Signal Maintenance Specifications

Technical Instruction

Issue date: 16th November 2023
Compliance date: 16th November 2023
Expiry date: 15th November 2024

Technical Instruction TI 182 is attached to this standard/control document.

This Technical Instruction mitigates an urgent safety/asset/equipment risk that cannot await a full review of this standard/control document.

This standard/control document will be reviewed and reissued before the emergency change expires on 15th November 2024.

User information

This Network Rail document contains colour-coding according to the following Red–Amber–Green classification.

Red requirements – *no variations permitted*

- Red requirements are to be complied with and achieved at all times.
- Red requirements are presented in a red box.
- Red requirements are monitored for compliance.
- Non-compliances will be investigated and corrective actions enforced.

Amber requirements – *variations permitted subject to approved risk analysis and mitigation*

- Amber requirements are to be complied with unless an approved variation is in place.
- Amber requirements are presented with an amber sidebar.
- Amber requirements are monitored for compliance.
- Variations can only be approved through the national variations process.
- Non-approved variations will be investigated and corrective actions enforced.

Green guidance – *to be used unless alternative solutions are followed*

- Guidance should be followed unless an alternative solution produces a better result.
- Guidance is presented with a dotted green sidebar.
- Guidance is not monitored for compliance.
- Alternative solutions should be documented to demonstrate effective control.

Compliance

This Network Rail standard/control document is mandatory and shall be complied with by Network Rail Infrastructure Limited and its contractors if applicable from 2nd March 2024.

Where it is considered not reasonably practicable[1] to comply with the requirements in this standard/control document, permission to comply with a specified alternative should be sought in accordance with the Network Rail standards and controls process, or with the Railway Group Standards Code if applicable.

If this standard/control document contains requirements that are designed to demonstrate compliance with legislation they shall be complied with irrespective of a project's Project Acceleration in a Controlled Environment (PACE) phase or equivalent governance framework. In all other circumstances, projects that have formally completed PACE strategic development & project selection phase may continue to comply with any relevant Network Rail standards/control documents that were current when PACE phase 1 was completed.

NOTE 1: *Legislation includes National Technical Specification Notices (NTSNs)*

NOTE 2: *The relationship of this standard/control document with legislation and/or external standards is described in the purpose of this standard.*

NOTE 3: *For more information on PACE see NR/L2/P3M/201.*

Disclaimer

In issuing this standard/control document for its stated purpose, Network Rail Infrastructure Limited makes no warranties, expressed or implied, that compliance with all or any standards/control documents it issues is sufficient on its own to provide safety or compliance with legislation. Users are reminded of their own duties under legislation.

Compliance with a Network Rail standard/control document does not, of itself, confer immunity from legal obligations.

Where Network Rail Infrastructure Limited has granted permission to copy extracts from Network Rail standards or control documents, Network Rail Infrastructure Limited accepts no responsibility for, nor any liability in connection with, the use of such extracts, or any claims arising there from.

This disclaimer applies to all forms of media in which extracts from Network Rail standards and control documents might be reproduced.

Supply

Copies of standards/control documents are available electronically, within Network Rail's organisation. Hard copies of this document might be available to Network Rail people on request to the relevant controlled publication distributor. Other organisations can obtain copies of this standard/control document from an approved distributor.

[1] *This can include gross proportionate project costs with the agreement of the Network Rail Assurance Panel (NRAP).*

1 Purpose

This document contains the index to the Signal Maintenance Specifications (NR/SMS) for signalling equipment on Network Rail Managed Infrastructure (NRMI).

2 Scope

This document applies to all staff who carry out corrective or preventative maintenance to signalling equipment on NRMI.

3 Index for NR/SMS

The indexes show the latest (current) issues of the individual NR/SMS documents.

NOTE: *Contractors are responsible for arranging and undertaking their own Detailed and Overview Briefings in accordance with their own processes and procedures.*

Signal Works Testing Handbook NR/L2/SIG/30014/D115

Note: All other activities can be safely undertaken unless disturbing paper gaskets and rope seals for which non-licenced asbestos work rules are to be followed. HW & Style 63 machines do not have paper gaskets or rope seals and the full range of asbestos-containing materials are captured in the archetypal reports for point machines.

[illegible]

NOTE: *The IMC040/IMC040A boards are used to process the information received from the strike-out wheel sensors. The Vamos crossing system uses the output from these boards to determine when to start displaying a green aspect to level crossing users.*

[illegible]

NOTE: *When the IMC040A boards have been accepted for use by NR, there will be separate communications regarding the arrangements for rolling these out to existing Vamos crossing systems and provision of them for use with new Vamos crossing systems.*

[illegible]

[illegible]	[illegible]
[illegible] Modul[illegible]	[illegible] ***NOTE:*** *Clause 3 of Appendix A sets out an additional process to support Routes in determining whether it is appropriate to bring a new Vamos crossing system into service at a particular level crossing in advance of the modified components being available.* *Clause 4 of Appendix A contains additional controls which apply should it be decided to bring a new Vamos crossing system into service at a particular level crossing in advance of the modified components being available.* *These controls align with current good practice as implemented on existing Vamos crossing systems in response to NR/SIN/211 and NR/SIN/212.*

[illegible]	[illegible]

[illegible]

[illegible]

Rationale: To provide an audit trail of decision making.

[illegible]	[illegible]
[illegible]	1
[illegible]	[illegible]
[illegible]	[illegible]

[illegible]

[illegible]

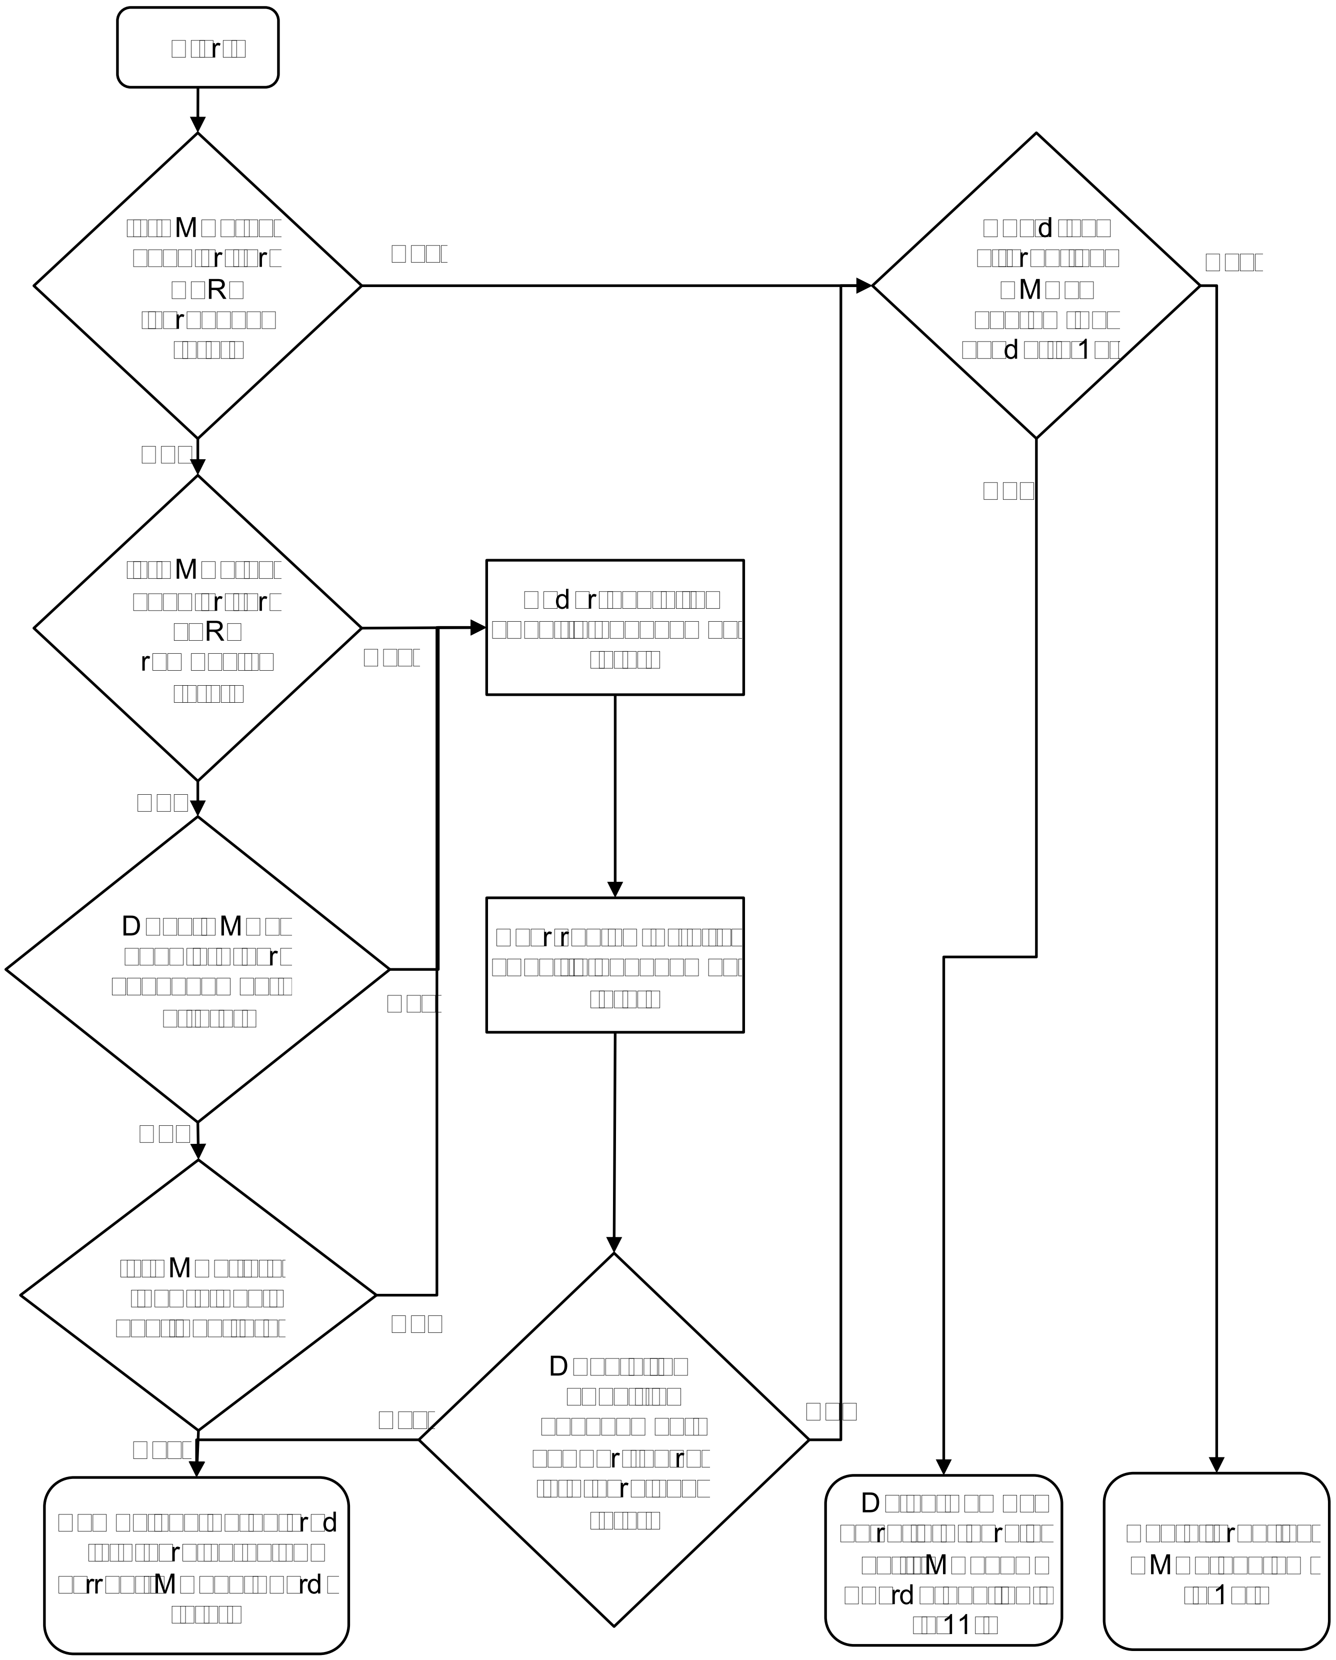
Rationale: To confirm that key accountable roles for asset and risk management at the level crossing are supportive of the intended actions.

[illegible]

[illegible]



[illegible]	[illegible]
[illegible]	1
[illegible]	[illegible]
[illegible]	[illegible]

[illegible]

[illegible]

[illegible]

Rationale: To avoid introducing a wrong side failure risk in situations where there is no existing safety hazard to be mitigated. Hazard review by a group of subject matter experts from across the Regions has concluded that it is not appropriate to bring a Vamos crossing system into service with the current IMC040 boards in situations where the provision of an OMSL solution is driven by a need to mitigate elevated hazards arising from a proposed increase in PSR.

Note: For the purposes of this process the current IMC040 boards are those referenced on product acceptance certificate PA05/05850 issue 8 (or earlier).

[illegible]

[illegible]

[illegible]

Note: The circumstances described in sections 3.4 and 3.5 may also be relevant at a particular level crossing. Where this is the case, these circumstances are also considered as part of the site-specific assessment.

[illegible]

Rationale: To allow a more detailed consideration of the risks and benefits associated with the potential introduction of a Vamos crossing system.

Note: The circumstances described in sections 3.3 and 3.5 may also be relevant at a particular level crossing. Where this is the case, these circumstances are also considered as part of the site-specific assessment.

Rationale: To allow a more detailed consideration of the risks and benefits associated with the potential introduction of a Vamos crossing system.

Note: The circumstances described in sections 3.3 and 3.4 may also be relevant at a particular level crossing. Where this is the case, these circumstances are also considered as part of the site-specific assessment.

Note: It is possible for more than one of the above circumstances to apply at a level crossing. The site-specific assessment undertaken for such a level crossing should consider all relevant circumstances and the factors which are applicable to them.

Rationale: To reduce the risk of the site-specific assessment failing to consider factors which influence hazards at the level crossing.

“window of opportunity” for the wrong side

Rationale: To reduce the risk of the site-specific assessment failing to consider factors which influence hazards at the level crossing.

Note: For guidance on items c) and d) in this requirement, refer to sections 3.6.5 and 3.6.6.

Rationale: To reduce the risk of the site-specific assessment failing to consider factors which influence hazards at the level crossing.

Note: For guidance on items c) and d) in this requirement, refer to sections 3.6.5 and 3.6.6.

The signaller's workload,

Rationale: To provide an audit trail of decision making.

Rationale: To achieve a consistent approach to the judgements which underpin the site-specific assessment activity and share good practice across NR.

[illegible]	[illegible]
[illegible]	1
[illegible]	[illegible]
[illegible]	[illegible]

[illegible]

Rationale: To provide a record of the discussion, any recommendations identified and the support (or otherwise) of the panel for audit purposes and to inform the Route's subsequent decisions on how to proceed.

[illegible]

Rationale: To confirm that the key accountable roles for asset and risk management at the level crossing are satisfied with the outcome of the site-specific assessment activities.

[illegible]

Note: Signage changes associated with the introduction of the Vamos crossing system cannot be implemented until the Vamos crossing system itself is brought into service. Covering over visual and audible warning devices avoids their presence misleading crossing users to expect a visual or audible warning.

INDEX

END

General

These systems have one type (DEK43) of rail mounted wheel detectors (heads). Wheel detection is provided by two different types of systems: ZP 43V Analogue (the original type) and ZPD 43 Digital.

The differences are limited to the components and method of operation of the equipment within the trackside connection box.

The voltages and frequencies transmitted between an axle counter evaluator and the ZP 43V and the ZPD 43 wheel detection systems are essentially the same

Currently two different AzS axle counter evaluator systems are in use on Network Rail infrastructure; these are the AzSM (E) and the AzS 350U.

Overview - Siemens (AzS series) Axle Counters

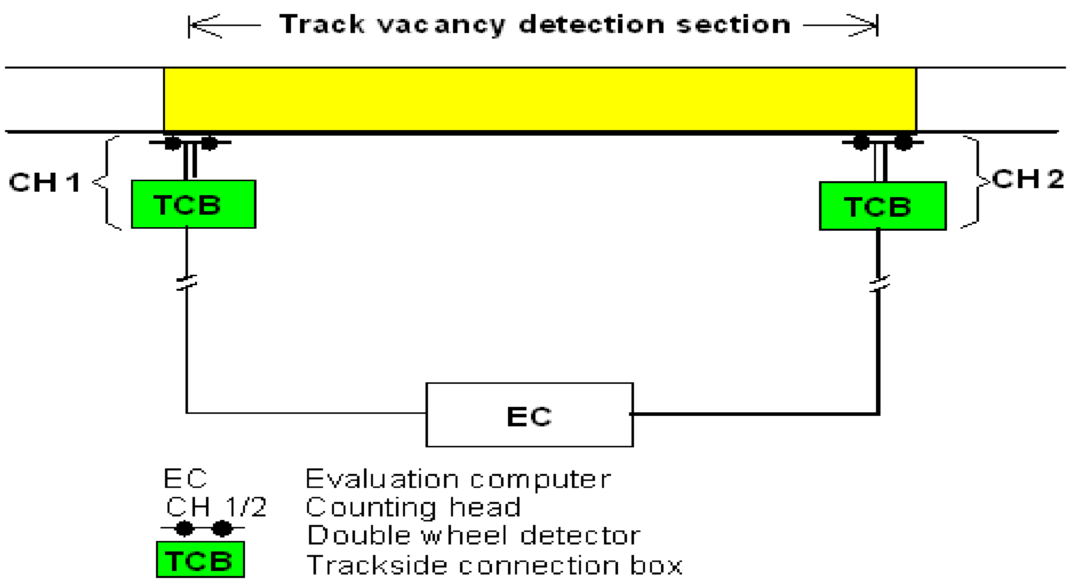

Figure 1 - Layout of Wheel Detection Equipment and associated components

The Wheel Detection Equipment consists of a rail mounted double wheel sensor and equipment within the trackside connection box that provides an output to the axle counter evaluator.

The DEK 43 consists of two detectors mounted in one unit on one rail that detects the passing wheels of the vehicles. As they pass, the wheels influence the electromagnetic field between the transmitter and the receiver of each detector; this alters the voltage induced in the receiving coil of the detector.

This voltage is converted by the trackside connection box to frequency/amplitude–modulated signals, which are transmitted to the evaluation computer.

The Evaluation Computer used can be either a AzSM (E) or a AzS 350U system. The ZAN card (in the AzSM (E)) or the VESBA card (in the AzS 350U) converts the signals from wheel detection equipment into a series of logic pulses so that the microprocessor in the evaluation computer can determine the train's direction of travel & the number of axles.

The Evaluation Computer interprets the signals transmitted by the counting heads. It then compares the numbers of axles, which have entered and left a track vacancy detection section to determine whether that track vacancy detection section is clear or occupied.

In the case of the AzS 350U evaluator the clear/occupied state of each track vacancy detection section determines whether the corresponding TR (track relay) is energised or de-energised, while the AzSM (E)) transmits the states of the track sections directly to the interlocking via the IL bus.

Up to 16 counting heads (ZP 43 V units) can be connected per evaluation computer in the AzSM (E) system. The AzS350U can have up to 5 counting heads (ZP 43 V units) connected per evaluation computer

DEK 43 Double Wheel Detector

The DEK 43 Double Wheel Detector consists of two electronic sensors. Each sensor (detector) has a transmitter and a receiver section.

The transmitter housing is located on the outer side of the rail, the receiver housing being on the gauge side of the rail.

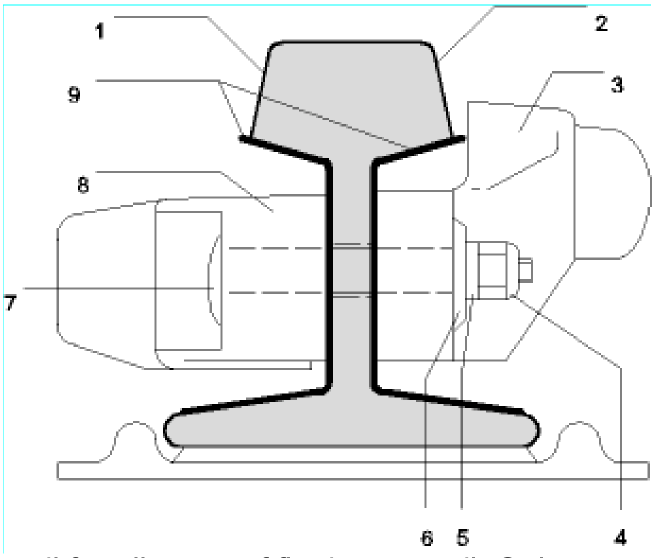
To prevent interference from the rail (due to track return currents), a reducing plate is fitted to both the transmitter & receiver.

The reducing plate is mounted on the side facing the rail. It is matched to the rail profile and reaches from the rail base across the web to below the railhead.

The double wheel detector is attached to the neutral zone of the rail web by two bolts.

DEK 43 Components

1. Gauge side of rail.
2. Outer side of rail.
3. Transmitter.
4. M12 prevailing-torque hexagon nut.
5. Spring washer.
6. Square washer.
7. Mushroom-head bolt.
8. Receiver.
9. Reducing plates.



Reduction plates are fitted to both sides of the rail for all types of flat bottom rail. Only one reduction plate is fitted on the receiver side for all types of Bull head rail.

ZP 43V Wheel Detection Equipment

This is used on the AzSM (E) and AzS 350U systems.

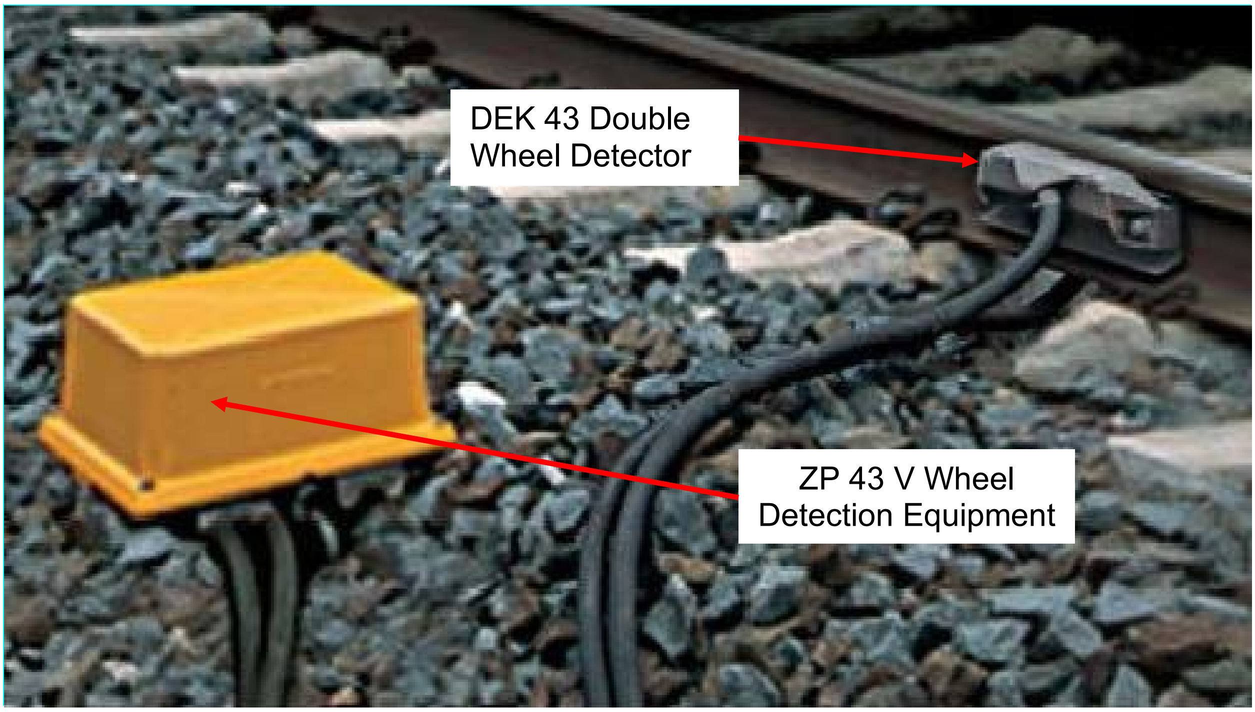


Figure 2 - ZP 43 V Wheel Detector Equipment

This equipment consists of a double wheel sensor (two detectors mounted in one unit on one rail) that detects the passing wheels of the vehicles. As they pass, the wheels influence the electromagnetic field between the transmitter and the receiver of each detector; this alters the voltage induced in the receiving coil of the detector.

This voltage is converted by the trackside connection box to frequency/amplitude–modulated signals, which are transmitted to the evaluation computer.

The ZAN card (in the AzSM (E)) or the VESBA card (in the AzS 350U) then converts these signals in to a series of logic pulses so that the microprocessor can determine the train's direction of travel & number of axles.

The equipment within the trackside connection box consists of vertical backplane with connectors where all incoming wires are terminated.

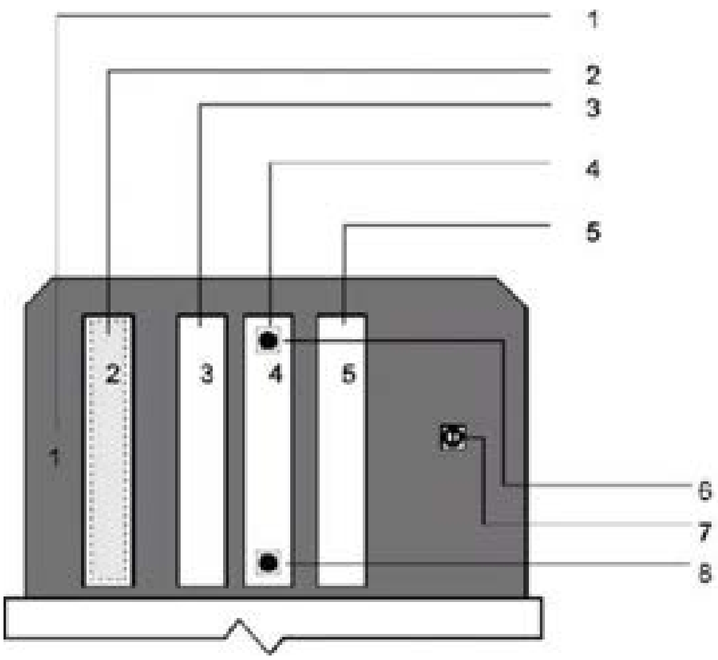
The backplane provides four circuit board connectors into which circuit boards can be plugged. Connector 3 is used for the Band Pass Filter board and connector 4 is used for the Generator board.

When it is necessary to take measurements, the PEGA 1121 test set is plugged into connector 2 (on the left hand side).

When adjustments have to be made during set-up and maintenance, this is done using potentiometers on the cards and on the backplane.

ZP 43 V Internal Layout

1 Wiring backplane.
2 Connection for WDE service equipment.
3 Band-pass filter board.
4 Generator board with adjusting control for signal frequencies.
5 Double-usage board.
6 Adjusting control for signal frequency f2(6.52 kHz)
7 Rotary switch for transmitting frequency (43 kHz)
8 Adjusting control for signal frequency f1(3.60 kHz)



Test Equipment

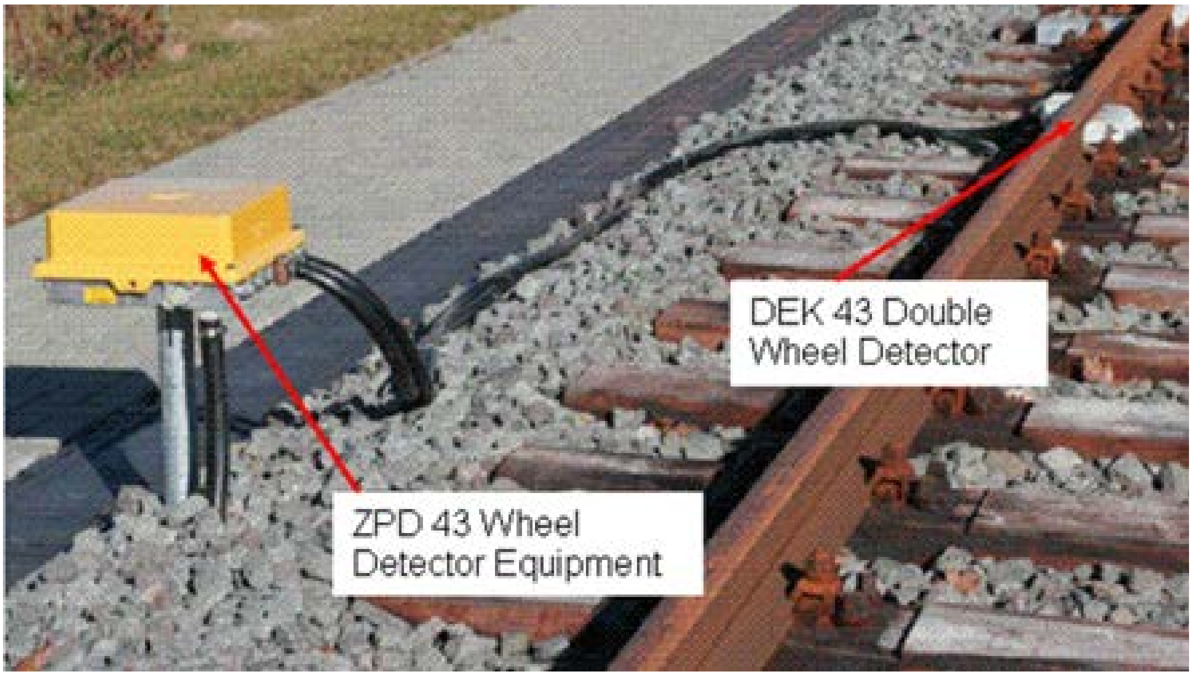
The PEGA 1121 test set is used for testing the ZP 43V.

1 Display
2 Test socket, positive input
3 Test socket, negative input
4 Round socket for WDE adaptor (WDE = Wheel Detector Equipment)
5 Display illumination, on/off
6 Operating mode/function indicator
7 Operating mode selector
8 Confirmation
9 Previous function/next-lower frequency
10 Next function/next-higher frequency

Check that the “ZP43” mode has been selected on the PEGA 1121 test set Check that the switch on the plug-in module has been set to “ZP43” (down) (The setting of the rotary switch is immaterial)

ZPD 43 Wheel Detection Equipment

This is used on the AzSM (E) and AzS 350U systems.



ZPD 43 Wheel Detection Equipment

This equipment consists of a double wheel sensor (two detectors mounted in one unit on one rail) that detects the passing wheels of the vehicles.

As they pass, the wheels influence the electromagnetic field between the transmitter and the receiver of each detector; this alters the voltage induced in the receiving coil of the detector.

This voltage is converted by the trackside connection box to frequency/amplitude–modulated signals, which are transmitted to the evaluation computer.

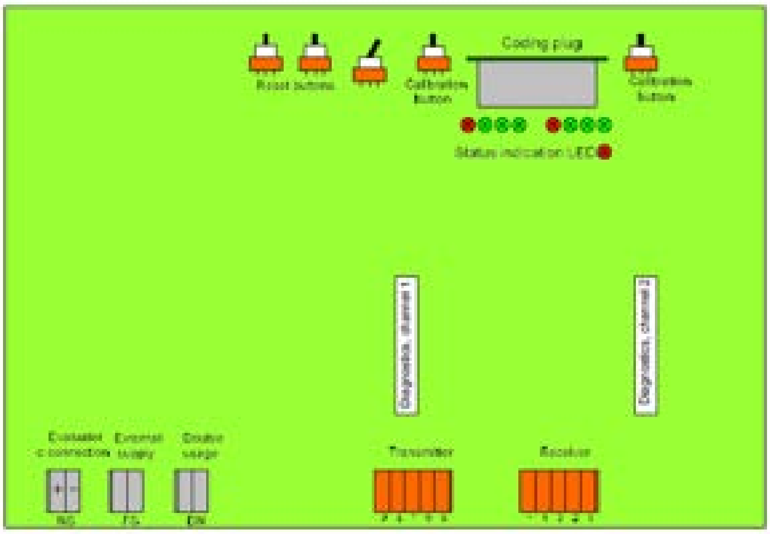
The ZAN card (in the AzSM (E)) or the VESBA card (in the AzS 350U) then converts these signals in to a series logic pulses so that the microprocessor can determine the train's direction of travel & number of axles.

The equipment within the trackside connection box consists of a single horizontal circuit board with connectors where all incoming wires are terminated, and on which the coding (identity) plug is located.

When it is necessary to take measurements, these are taken at the connector terminals, using an approved meter (Fluke 187 or similar).

When adjustments have to be made during set-up and maintenance, this is done using the pushbuttons this circuit board. The process is automated with no manual adjustments required.

ZPD 43 Internal Layout



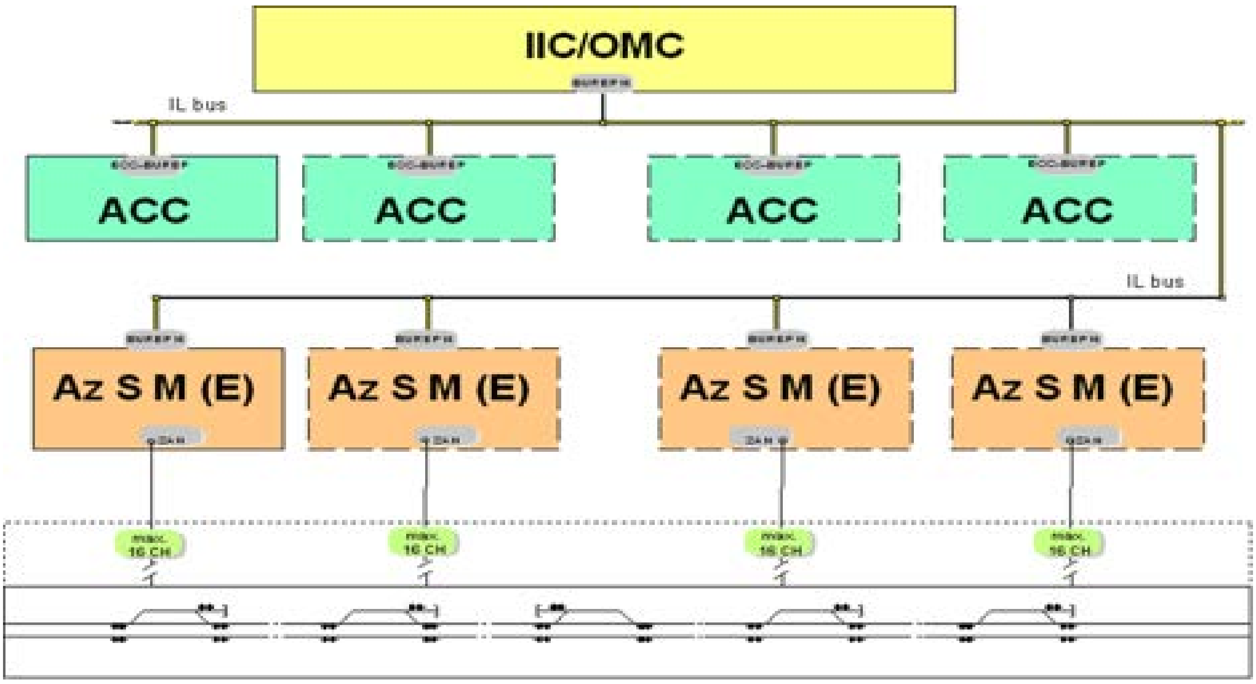
Test Equipment

All measurements are to be taken using an approved true RMS meter with frequency scale and with an internal resistance ≥ 50 kΩ (e.g. Fluke 187).

AzSM (E) Systems

The AzSM axle counter is a microcomputer based system with a multiple section evaluation computer for the track vacancy detection of track sections. The AzSM (E) variant is designed to interface with the Siemens SIMIS-W interlocking:

AzSM (E) System Architecture



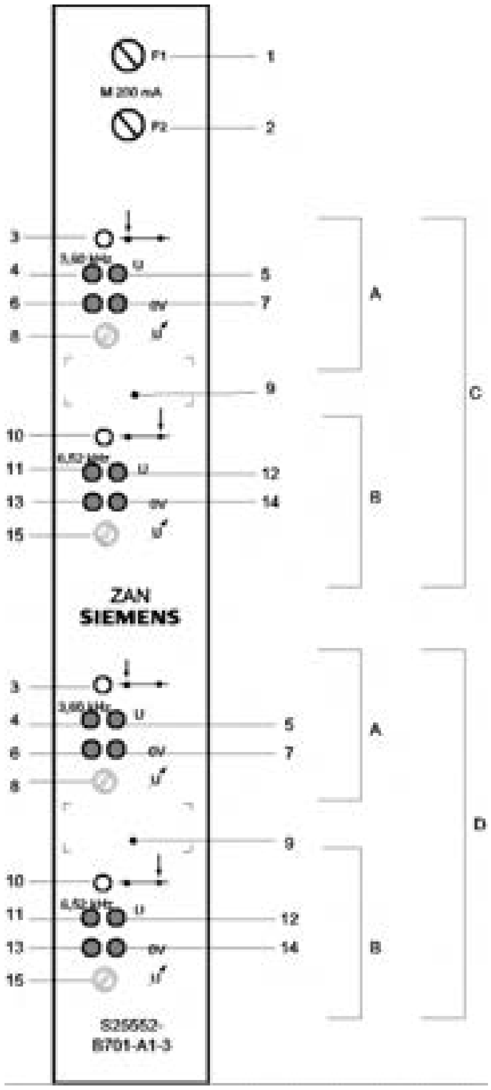
Abbreviation	Meaning
IIC/OMC	Overhead computer
ECC-BUREP	Element Control Computer interface board between computer & bus
BUREP	Interface board between computer bus
IL Bus	Interlocking Bus
ACC	Area Control Component (computer)
AzSM (E)	Axle counting system for multiple sections

Structure/Function

The AzSM (E) Axle Counting System consists of two main components:

a) Indoor system: evaluation computer (EC). The hardware is based on the SIMIS 3216 computer, connected to the ACC via the IL bus.
b) Outdoor system: ZP 43V Wheel Detection Equipment.

Evaluation Computer Test Points & Indications



Key to Test Points & Indications		
No.	**Item**	**Comment**
A	System 1	
B	System 2	
C	Counting Head 1	(System 1 & 2 of double wheel detector)
D	Counting Head 2	(System 1 & 2 of double wheel detector)
1	M 200mA	Fuse, counting head1
2	M 200mA	Fuse, counting head 2
3	LED Yellow	System 1 of double wheel detector being traversed.

5	Test Socket	Voltage U1 = 3.0V DC +/- 0.10v
6 & 7	Test Socket	0v sockets for both systems.
8	Potentiometer	Voltage adjustment to 3.0 V DC +/- 0.10V
9	Space for Label with CH	
10	LED Yellow	System 2 of double wheel detector being traversed
11	Test Socket	f2 = 6.52khz +/- 0.10 KHz (frequency adjustment at counting head)
12	Test Socket	Voltage U2 = 3.0v +/- 0.10v
13 & 14	Test Socket	0V socket for both systems
15	Potentiometer	Voltage adjustment to 3.0 V DC +/- 0.10V

AzSM (E) - Reset & Restore Procedures

The re-set and restore of the Siemens AzSM (E) axle counter is performed by the signaller.

The reset & restore procedure can be performed only when:

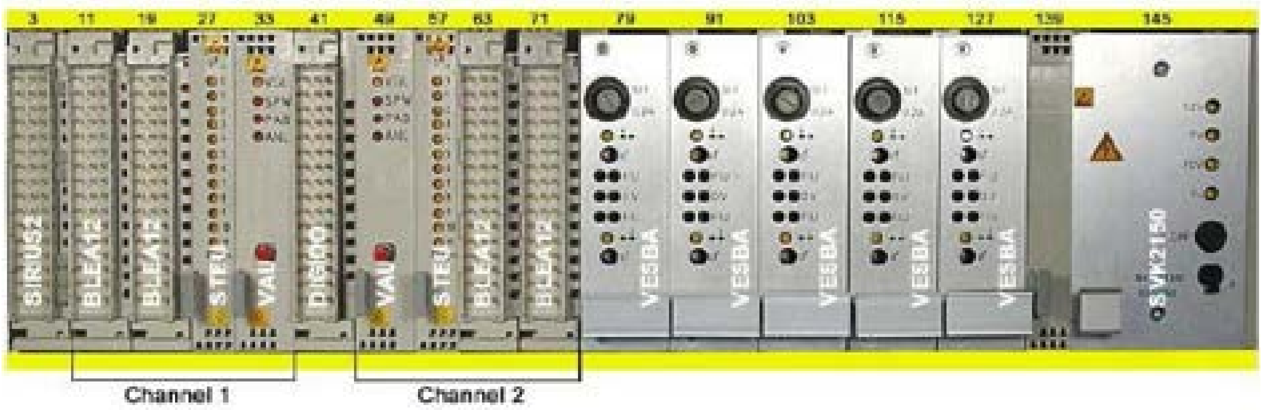
a) An axle counter section remains occupied after the passage of a train when the track section is “clear” or
b) Requested by the technician if the elements are indicated as being occupied when the axle counter section (s) is ‘clear’ (e.g. after the restart of an evaluation computer (EC) due to failure or maintenance work or after other faults)

The axle counter reset & restore procedure is split into the following stages:

a) Applying protection
b) Resetting the section
c) Restoration to normal working

AzS 350U Systems

AzS 350U ACE rack



The system can evaluate up to four track sections.

Structure/Function

The AzS 350U Axle Counting System consists of two main components:

a) Indoor system: evaluation computer (EC). The hardware is based on the 8085 microprocessor VAU board microcomputer system.
b) Outdoor system: ZP 43 Wheel Detection Equipment.

Evaluator Computer

This interprets the signals transmitted by the ZP 43 wheel detection equipment. It can connect to five ZP 43s directly and a further six remotely via two other evaluator computers. It compares the number of axles entering and leaving a tack section and outputs the track section state via voltage free contact relays. The evaluator computer can also be used as a transmission system for vital signal functions.

Before removing any board reference should be made to the Siemens maintenance manual. Following the correct removal/re-fitment procedures is critical to the operation of the axle counter.

AzS 350U - Reset, & Restore Procedures

The re-set and restore of the Siemens AzS 350U axle counter is performed by the signaller.

The reset & restore procedure can be performed only when:

a) An axle counter section remains occupied after the passage of a train when the track section is "clear" or
b) Requested by the technician if the elements are indicated as being occupied when the axle counter section (s) is 'clear' (e.g. after the restart of an evaluation computer (EC) due to failure or maintenance work or after other faults)

The axle counter reset & restore procedure is split into the following stages:

a) Applying protection
b) Resetting the section
c) Restoration to normal working

End

Contents

1 T72 POINT MACHINE

1.1 General Information

Any deficiency or failure, which could affect the safe running of trains or the integrity of the signalling system, shall be reported to the signaller immediately.

Before working on points:

- Set up possession and protection arrangements with the signaller.
- Check that a route cannot be set over the points being worked on (staff and safety of trains). This requires the implementation of a safe system of work which may include:
- Provision of a point operator at the controlling point.
- Verify the point end by asking the signaller to swing the points prior to starting work.
- A locally documented procedure.

1.1.1 Defects

Defects that could affect the safe operation of trains shall be advised to the signaller immediately.

Defects should be repaired as soon as possible. Where not rectified at the time, inform your SM (S).

If the point identification number is displayed on the detachable lid instead of on the machine body, check that when working on adjacent machines the lids are not inadvertently swapped. Incorrect point identification may result.

1.2 Mechanical Information

The Ansaldo Signal (CSEE Transport) type T72 point machine has a cast iron body which houses the control module, motor, and gear train with integral clutch. A lip is incorporated along each side of the machine body to enable it to be carried ‘stretcher style’ with two crowbars.

The separate steel lid is normally secured with four quick release clips, two of which can be secured with padlocks. However, to provide a more robust means of securing the machine against unauthorised access, the lid has been fitted with two lugs which engage the slotted blocks fitted to the machine body. A hasp and staple has also been fitted and is secured with an RKB221 padlock. A second RKB221 may be fitted to one of the quick release clips.

An RKB222 padlock is fitted to the crank handle access lever bracket.

In addition to the RKB222 padlock, the crank handle access lever is also secured by a fixed lock operated by a barrel type key. The fixed lock shall also be unlocked to allow the lever to be moved to the '*Hand'* position. The key is captive in the lock until the lever is restored and locked in the '*Motor'* position.

When the lid is removed, put it in a place of safety, preferably under cover or face down to prevent accumulation of rain, dust, grit, or foreign bodies in the cover being inadvertently transferred to the machine.

The first version of the point machine supplied to the UK had a 4.7 kN clutch setting, an internal diode, a thermostat plate that restricted the access to the fourth motor brush and a wiring anomaly. These machines have been superseded by machines with a 6 kN setting to meet the requirements for operating RT60 layouts and have been modified to remove the diode, provide an alternative thermostat mounting plate which allows access to the fourth motor brush and corrects the wiring anomaly. 6 kN machines are identified by means of the identification plate on the outside of the machine as follows:

Point machine label showing version E and 6 kN

Only machines with labels as shown above bearing the version E and 6 kN markings can be used. Any machines found without these labels or with other than version E and 6 kN shall NOT be used and your SM (S) shall be informed immediately so the machine may be placed in quarantine until it can be returned to the servicing agent or manufacturer.

1.2.1 Fixing

Four lugs each with a 20 mm diameter hole.

1.2.2 Size

750 mm (L) x 620 mm (W) x 215 mm (H)

1.2.3 Weight

150 kg

1.2.4 Throw

The throw of the machine can be adjusted between 105 mm and 260 mm by loosening the drive arm clamp and shortening or lengthening the drive arm as required. See Ansaldo Signal – T72 Point Motor DC Permanent Magnet Type - Manual 2 - Installation and Use – section 6.5 - Setting and Adjusting the Throw.

The drive arm clamp is secured with two hexagonal head screws locked with tabs on a common tab washer plate.

The tab washer plate shall be renewed every time the tabs are bent away to permit loosening / removal of the hexagonal headed screws (i.e. the tab(s) shall not be re-used).

The required drive rod varies according to the point layout on which it is being used. The drawings detail the components required for each layout.

1.2.5 Balance

The balance of the throw can be adjusted by shortening or lengthening the drive rod, such adjustment is necessary, in conjunction with the adjustment of the throw of the machines, to check that the correct switch openings are achieved.

1.2.6 Mid stroke indication

The point machine is in the mid stroke position when the line or groove on the output shaft is aligned with the pointer on the machine nose. Some machines may have spots of red paint as alignment indicators.

1.2.7 Drainage

A water drain device is fitted adjacent to the gear wheel assembly. A screw driver is required to open it. The device should be closed when drainage is complete.

If the machine has been flooded or is suspected of having been flooded, then the complete machine shall be replaced and the ‘flooded machine’ returned for refurbishing.

1.3 Electrical Information

1.3.1 External connection

Either a single 3 m or 5 m length of CMA 24 cable terminated with plug couplers connects the machine to the junction box. The threaded connector ring at the point machine end is tightened with a hook spanner. Provision is made for fitting locking wire. The armour cable sheath is secured to the plug coupler body with a worm drive clip.

During transit the plug coupler sockets are fitted with protective caps.

Before connection, especially if replacing a machine check that the plug coupler is free of any debris and contamination.

1.3.2 Internal connection

The internal cable connections are secured with ‘Faston’ clips. However, no internal connections are required to be made during installation or removal of the machine.

1.3.3 Motor

DC permanent magnet type motor operating between 90 volts dc to 170 volts dc. The control module restricts the current delivered to the machine to 7A, so that the 7A rating of the motor contacts is not exceeded.

The control module cuts off the power supply to the motor when the current falls to zero as a result of the internal control contact in the T72 opening when it nears the end of its travel. The control circuit includes a timer that cuts the current after between 6 - 9 seconds if the contacts have not opened in this time.

The T72 clutch protects the motor between encountering an obstruction and the timer becoming effective.

The motor cannot be replaced on site.

1.3.4 Motor brushes

The motor is fitted with four brushes. Each spring loaded brush assembly is retained by a threaded plug slotted to accept a wide blade screwdriver or coin. The brush cap may require assistance to ‘pop-up’ if the side arms bind in the brush guide slots.

When a brush has worn to the minimum permitted length (8 mm), renew it.

1.3.5 Heater

A thermostatically controlled 100 W (at 110 V) heating resistor is fitted to the gear train cover plate.

1.3.6 Clutch

A friction type clutch, mounted in the reduction gear assembly, absorbs the inertia of the motor and gears as the motor starts and stops or in the event of an obstruction preventing closure.

The clutch cannot be adjusted or serviced on site.

1.3.7 Isolation

Moving the selector lever from *‘Motor’* to *‘Hand’* causes an internal isolation switch to operate and permits access for the point crank handle.

1.3.8 Manual operation

Manual operation is via a spring loaded shaft fitted with a small gear wheel. The spring checks that the gear wheel is disengaged from the motor driven gear train when not required. Consequently, the crank handle should be pushed in during manual operation to keep the small gear wheel engaged with the main gear.

Non-UK versions of the T72 are manually operated by a long lever which is normally secured flat to the ground by a padlock. The crank handle is provided for the UK version of the T72, but the claw type clutch / bevel gear assembly for manual operation by lever remains. This is engaged and operates during manual operation.

1.3.9 Heater or Thermostat - replacement

If the heater and / or thermostat are replaced their correct operation shall be checked (NR/SMS/Test/170).

1.4 Spares and Replacements for the T72 Point Machine)

The following components can be replaced on site:

Component	CSEE Transport Part Number
Motor brushes	6520403-00 (electric motor reference)
Drive arm	6520354-01
Lid	2012491
Heater kit	6522389-10
Thermostat	6004122-00
Crank handle	2010063

Other components may be specific to the particular layout on which it is used. The drawings detail the replacement components required for specific layouts.

1.5 Tools

Open-ended spanner – 27 mm.

Hexagonal sockets – 24 mm and 27 mm.

‘Hook’ spanner (plug coupler) ‘FACOM’ – number 125 – 120.

Grease gun with Tecalmit type fitting

Other tools required include hammer, small drift (for securing washer tabs), combination pliers, insulated metre rule, and screwdriver (water drainage screw).

1.6 Torque Values

Component	Torque Values
Bolt and castellated nut connecting each crank control arm to coupling rod	15 Nm (maximum)#
T72 point machine fixing bolts	110 ± 10 Nm

#: If, when the nut has been tightened to 15 Nm, the security split pin cannot be fitted, the nut should be carefully slackened to align the first available slot with the hole in the bolt.

1.7 Lubricants

Lubricant	CSEE Transport part number
'SHELL' Rimula C oil for diesel engine Viscosity SAE 20W-40	6004075-00
'SHELL' Retinax HD Grade 2 grease – Multipurpose grease (blue)	6004075-00

The named lubricants shown above are recommended by the equipment manufacturer. Equivalent lubricants may be used.

2 COGIFER VCC LOCK & DETECTION MECHANISM

2.1 VCC Lock

2.1.1 Lock Mechanism

The VCC lock mechanism for the Network Rail applications are supplied to fit 113lb FB, UIC54, and RT60 rail sections. These three types are identified as follows:

The P80 version is used on full depth switch rails (113lb).

The M89 version is used on shallow depth switch rails (UIC54).

The M80 version is used for RT60/NR60 layouts.

The version of the VCC is stamped on the C-arm and adjacent to the entry hole for the "hammer head bolt" on the inside of the body of the VCC itself.

They differ in the switch rail fittings, the design of the switch rail bracket being the most obvious difference. The M80 and M89 bodies are similar but the RT60 version is for inclined rail and the UIC54 for vertical.

Check that the correct components for the particular configuration are available to suit the particular site requirements before starting work.

A left and right hand assembly is required for each installation. The handing is embossed on the lock body casting adjacent to the hole in the web that fits to the rail. 'G' Gauche - Left hand or 'D' Droite - Right hand. (The 'handing' is determined by facing the point toe).

The upper surface of the bearer on which the VCC lock and detection assembly is mounted shall be lower than the adjacent bearers to accommodate the VCC base plate which is an integral part of the VCC assembly. This bearer is usually a hollow steel bearer which is thinner than the surrounding concrete bearers.

2.1.2 Required Switch Opening

The required switch opening is greater than that normally provided on UK point layouts. The locking arrangement not only locks the switch rail to the stock rail but also locks the open switch open.

If the switch opening is insufficient, the crank arm is unable to complete its travel and lock the switch rail open. Failure to lock may therefore be due to the lock being tight on the closed switch side or inadequate switch opening on the open switch side.

The required switch opening for a 113A full depth layout is 115mm. 110 mm is the required switch opening on a shallow depth (UIC54) and RT60 switches.

2.1.3 VCC Exterior Cover

The crank head, locking piece and detector are protected by a cast iron cover retained by two spring hooks and secured against unauthorised access with an RKB221 padlock.

2.1.4 Lock Arm Stroke Balance

The crank head of a lock arm shall fully engage its respective locking piece when the switch rail is closed and locked in either normal or reverse position.

The amount of engagement for either lie of points should be as near the same as possible. To achieve this condition the coupling rod that operates the lock arms shall be adjusted so that the stroke of both lock arms is the same (in balance).

2.1.5 Checking the Lock Arm Stroke Balance

When the points are correctly set, the lock arms should both cover the locking surfaces fully and equally. If the stroke balance is incorrect – i.e. one lock arm travels further than the other, then the drive rod length is incorrect. If both lock arms travel the same distance but either travel too far or not far enough, then the drive arm of the T72 is the incorrect length.

The stroke balance can be checked by manually operating the points and noting the position of the crank head relative to its locking piece (distance of crank head from inner face of the casting) when the relevant switch rail is closed and locked. Repeat the procedure for the opposite lie of points and compare the amount of engagement (distance of crank head from inner face of the casting) with that previously observed.

For either lie of points, the amount of engagement should be approximately the same ± 3mm.

If the amount of engagement is not within the permitted tolerance then the cause shall be investigated and remedial action taken.

For further details refer to Cogifer VCC Clamp Lock Maintenance Manual 1010-100-005 or VCC Clamp Lock Installation Manual 1010-100-004

2.2 Detector

2.2.1 Detector Mechanism

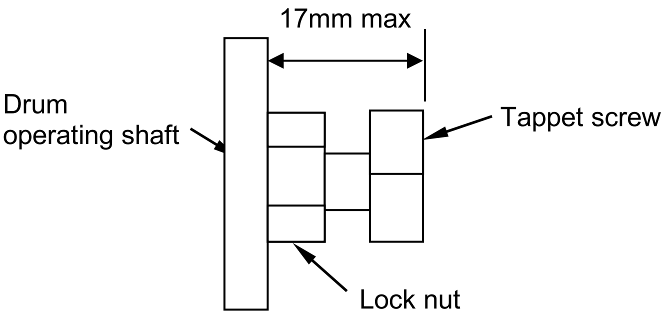
The detector drum and contacts are protected by an internal metal cover incorporating an insulation strip secured with rivets. The cover is a push fit and there is a risk that the wire insulation may be damaged by the sharp edge of the cover especially when the cover is refitted. Take care when fitting these covers as it is possible that, in extreme circumstances, damage to two of the wires insulation could result in false detection. If the wire insulation has been damaged arrange remedial action as appropriate.

2.2.2 Replacing a detector

If it is necessary to replace a detector, take care as it is very easy to bend the detector finger and/or damage the contacts.

It is very important that the following procedure for changing a detector is followed.

- Check that the detector is in switch open position (finger in pre-engagement notch).
- Check that the points are in the switch open position.
- Insert the plunger gauge through the hole in the stock rail.
- Fix the detector in place – 2 screws (cross-corners) will suffice at this stage.
- Set the tappet screw on the detector so that it is one to two turns out.
- Lever the finger open so that 6 mm gauge can be inserted — don’t lever against plunger gauge.
- Close and lock the switch (do this slowly, checking that the finger engages with the slot in the lock arm).
- Unscrew plunger gauge until it makes contact with tappet screw head.
- Unlock and open the points.
- Remove the 6 mm gauge checking that the finger is in the detector’s pre-engagement notch.
- Remove the detector.
- Remove plunger gauge without adjusting it.
- Cut the new plunger to the gauge length.
- Insert the plunger through the stock rail.
- Fix the detector using all four screws.
- Close and lock the points – watch the movement to check that it operates properly.
- Adjust the tappet screw (max. 17 mm) until the gauge is a sliding fit.



Detector adjustment showing maximum screw extension

- Repeat for the other detector.

2.2.3 Detector Electrical Connections

The terminal connectors used on the VCC are standard M6 ring tongue crimps with a black sleeve.

2.2.4 Cable Clamps

The cable clamps supplied with the equipment do not always adequately clamp the cables. Consequently the standard tail cable may not be sufficiently secured by the cable clamp. An additional sleeve may be required.

An alternative clamp has been supplied so that the cable is secured correctly; these should be recovered from units being replaced and re-used on the new units.

2.3 VCC Lock and Detector Spares and Replacements

2.3.1 VCC Lock and Detector

The following components can be replaced on site. However, due to the dismantling required to replace the lock crank wear pads, it is recommended that the complete lock crank assembly is replaced.

The oblong plastic sleeve on which the lock crank assembly slides should also be replaced to avoid unnecessary dismantling.

When replacing a lock crank assembly you cannot assume that the previous settings, packing and gauging of the associated components are still valid. The lock crank assembly may appear like for like but the replacement shall be treated as a new installation and the full installation procedure shall be applied.

See the relevant sections in Cogifer VCC Lock and Detector Mechanism manual.

When replacing the detector, check that the finger correctly engages the notch in the crank head. Otherwise the lock contact fingers, beneath the white plastic cover hinge, will be twisted and the contact gap reduced. A false circuit may be created.

If the VCC lock frame assembly requires replacement because of a ‘run through’ or suspected ‘run through’ then both VCC assemblies shall be replaced.

Component	COGIFER part number
Plastic sleeve	Specify VCC type
Wear pad kit: 1 x crank head pad 1 x fixing screw 1 x crank support pad 2 x fixing screws	871920025
Locking piece kit: 1 x locking piece 1 x castellated screw 1 x securing screw	871920009
Adjusting Shim Set (various thicknesses) (different material)	Specify VCC type Specify :stainless steel
Stabilising device: 1 x roller stabiliser 1 x spring 1 x stopping plate 1 x stopping ring	871920056
VCC cover retaining spring (2 required for each cover)	314040003
Hollow bolt kit: 1 x Ø27mm hollow bolt 1 x spring washer 1 x nut	Specify VCC type
Hammer head bolt kit: 1 x hammer head bolt 2 x spring washers 2 x flat washers 1 x slotted nut 1 x split pin	Specify VCC type
Lock crank assembly: 1 x lock crank 1 x lock crank bracket 2 x hammer head bolt kits 1 x stabilising device 1 x crank head pad 1 x control arm support pad	Specify VCC type

Component	COGIFER part number
VCC Detector kit: 1 x detector 1 x brass plunger 1 x terminal bag* *Note: Only the flat washers and nuts are required. The wires are terminated with black ring tongue crimps. Dispose of the remaining Paulvé terminal components in accordance with local instructions.	872220002 (Left hand model P80 - C9470)
	872120002 (Right hand model P80 - C9470)
	872220001 (Left hand model M80 & M89)
	872120001 (Right hand model M80 & M89)
Brass plunger (VCC Lock) (length 135 mm)	333050001

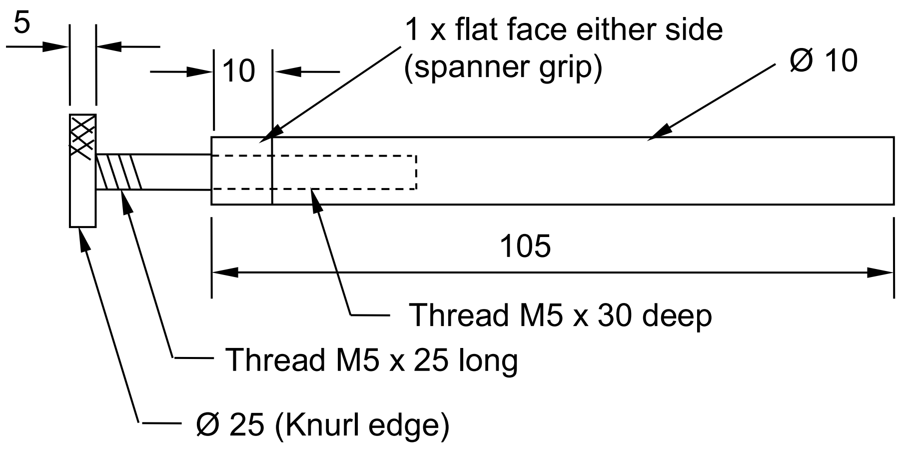
2.3.2 Wire Termination

Description	NRS part number
Terminal, crimp, ring tongue, M6, black sleeve	0054/119568

2.3.3 Gauges

Description	COGIFER part number
13/26mm	377001002
6mm ('U' shaped)	377001000

2.3.4 Special Gauge (Plunger Length Assessment)



Material: Silver steel or similar non rusting material (remove burrs and sharp edges)
Dimensions are in mm

The gauge may provide an alternative means of assessing the length of a replacement plunger

An alternative method for determining the plunger length is detailed in the manufacturer's installation manuals making use of callipers, a ruler and marking device if the above 'Gauge' is not available.

2.3.5 VCC Lock and Detector Lubrication

Description	Type
Lubricant	BP Energrease LS EP

The named lubricant shown above is recommended by the equipment manufacturer. An equivalent lubricant may be used.

2.3.6 VCC Lock and Detector Tools

Open-ended spanner – 13mm (2 required)

Hexagonal socket – 10mm

Torque wrench – range up to 400Nm

Other tools required include: feeler gauges, file, hacksaw, rule, screwdriver, and drill.

A small pair of inside callipers may be useful when:

- Measuring the projection of the brass plunger.
  (7.3).
- Measuring the gap between the hollow bolt and the top face of the tappet screw.
  (7.3).
- Measuring the length of the tappet / lock nut assembly.
  (7.3).

Ø 4mm drill – drilling hammer head bolt for split pin to secure castellated nut.

2.3.7 VCC Lock and Detector Torque Values

Component	Torque Values
VCC lock body to stock rail (Ø27mm hollow bolt)	40 Nm (maximum) *(Initial assembly to mate lock body with rail web) Shall be loosened before finally tightening to value below*
VCC lock body to stock rail (Ø27 mm hollow bolt)	300 ± 20 Nm
Bolts [3 off] securing VCC body to concrete bearer	300 ± 20 Nm
‘T’ head bolt with rail foot clamp securing rail to VCC body (steel or concrete bearer)	160 ± 15 Nm
Bolt with rail foot clamp securing rail foot to VCC body through to concrete bearer	160 ± 15 Nm
M12 x 35 hex. head screw either side of lock body	50 ± 5 Nm
Coupling rod / control arm connecting bolts	15 Nm (maximum) *(Slacken nut if necessary to insert split pin)*
Drive rod / coupling rod connecting bolt	15 Nm (maximum) *(Slacken nut if necessary to insert split pin)*

2.4 Fault Finding on the Detection Circuit

Typical faults on the detection circuit are likely to be:

- **Open Circuit:** Contact open because detection should not be made or broken wire;
- **Short Circuit:** Cable damage;
- **High Resistance:** Defective contact.

The conventional means of testing for the presence of a voltage is difficult with this circuit and so an alternative method is available. The circuit is terminated in a capacitor which is part of a tuned circuit. There is a 33 kΩ resistor across this capacitor which can be used for testing purposes.

The circuit should be first disconnected at the Junction Box by slipping the incoming detection feed links T1 1, T1 3 and T3 3. A meter on resistance setting is then put across the detection circuit T1 1 (right hand) or T1 3 (right hand) to T3 3 (right hand).

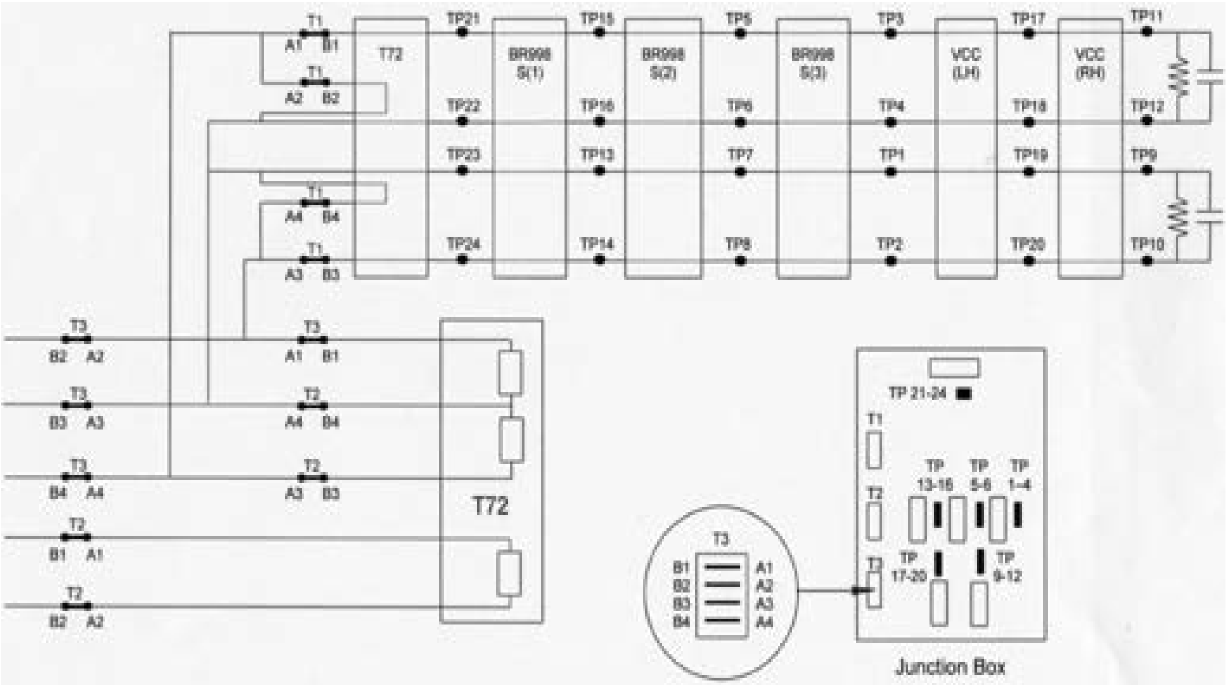
If the meter reads much greater than 33 kΩ, then it is likely that there is an **open circuit**. The test should be carried out on other sections of the circuit to localise the fault.

If it reads only a few ohms then this indicates a **short circuit**. Further testing is then required to localise the fault.

If the meter reads about 33 kΩ but the detection circuit does not operate, the n **high contact resistance** should be suspected. Test points are provided to test most contacts in the circuit (see simplified diagram for details of the test points). Test each contact in turn to determine its contribution to the total circuit resistance. The total series resistance of all the detection contacts measured at the junction box should be less than 1 Ohm. Cable resistance should be 5 Ohms or less. The total detection circuit resistance measured at the DEV card input should not be more than about 5 Ohms. If the total resistance exceeds 45 Ohms the DEV card will not operate correctly.

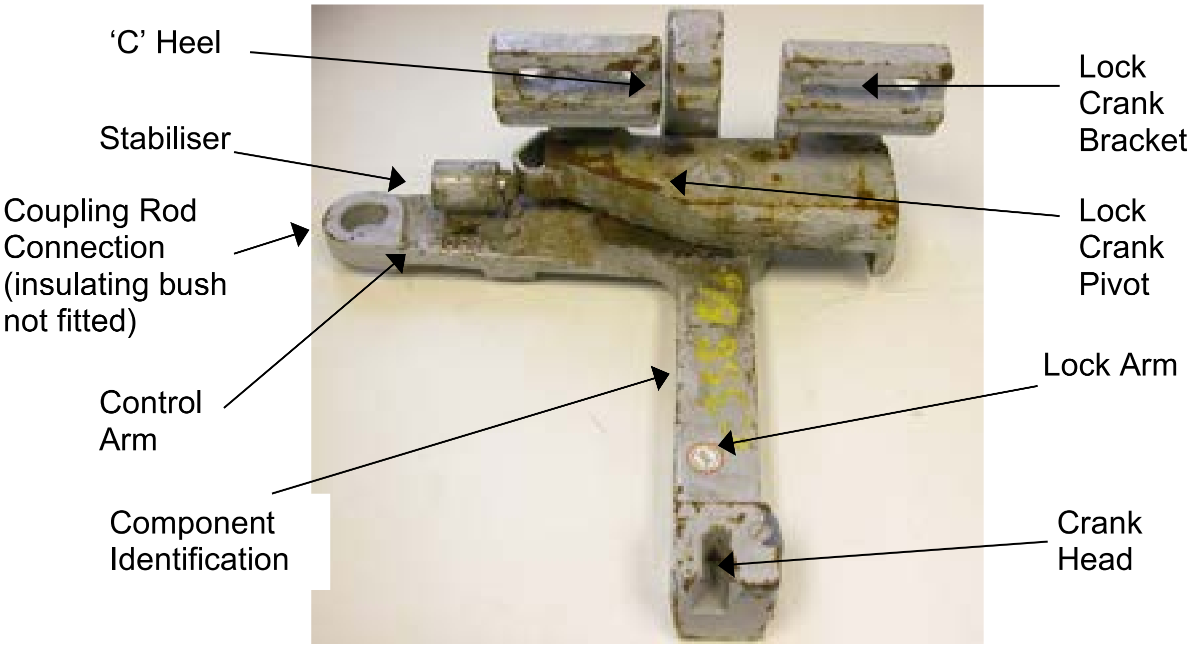
Simplified Point Circuit – New Junction Box

NOTE   Only the Test Points and principal components are shown in the diagram, i.e. contacts within the equipment are not shown.



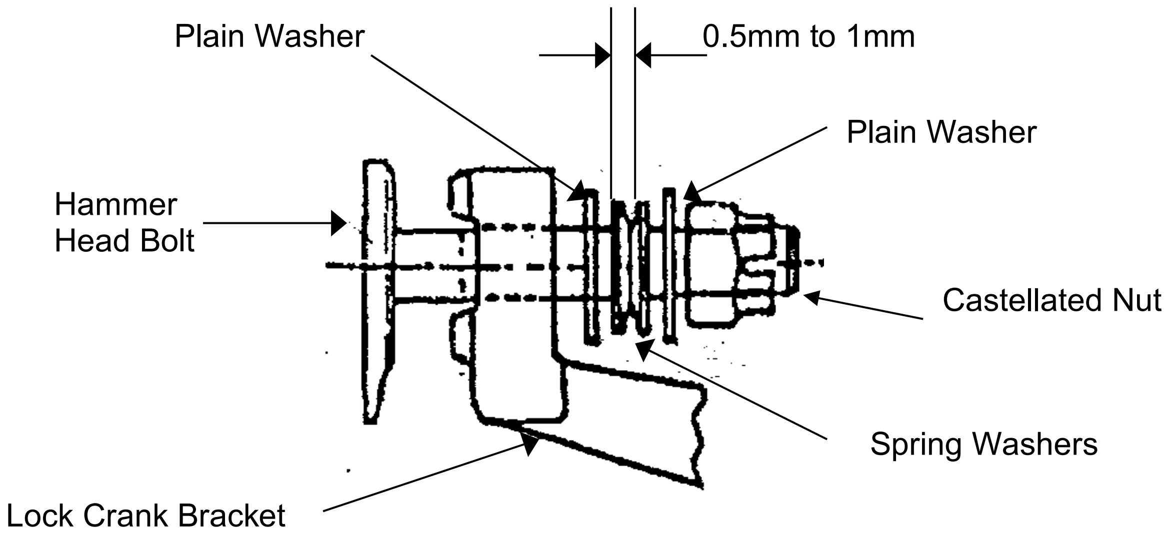
2.5 Component Details

2.5.1 Lock Crank Bracket ('C' arm) Assembly



Lock crank bracket ('C' arm) assembly for RT60 type rail. (Assemblies for UIC54 and 113A rail types are similar)

2.5.2 Detail (Hammer head bolt assembly)



3 CORRECTIVE & PREVENATIVE MAINTENANCE DETAILS FOR THE T72 POINT MACHINE AND VCC LOCK AND DETECTOR

3.1 Method of performing the Detection Test on the VCC Detector

Use the double ended 13/26 mm gauge to determine the operation of the lock contacts relative to the crank head position as it engages the locking piece during manual operation.

Figure 1

To check that the point detection is not ‘light’, the optimum moment of detection should occur midway between the 13 mm and 26 mm gauge positions. (Figures 2 and 3).

In Figure 2 and Figure 3 the crank head is shown moving towards the locked position (manual operation).
(The detector body has been removed for clarity).

Figure 2

The 13 mm gauge shall NOT overlap the locking piece.
If the gauge distance is less than 13 mm then the contacts are making late.

Figure 3

The 26 mm gauge shall overlap the locking piece.
If the gauge distance is greater than 26 mm then the contacts are making early.

3.2 Adjustment of the Detector Cam Stroke Tappet Screw

1. Open the switch blade.
2. Release the tappet screw lock nut.
   (Two 13 mm spanners are required)
3. Close and lock the switch blade.
4. Adjust the tappet screw until the 6 mm 'U' shaped gauge is a sliding fit.
5. Remove the gauge.
6. Open the switch blade.
7. Tighten the tappet screw lock nut.
   Check that the tappet screw does not move.
8. Close and lock the switch blade.
9. *Gauge* the stroke of the detector cam shaft.
   If correct proceed to clause 10 otherwise remove gauge and return to clause 1.
10. Remove gauge.
11. Open the switch blade.
12. *Measure* the overall length of the tappet screw and lock nut assembly (*7.3, Figure 4*).
    If greater than 17 mm, the cause shall be investigated and rectified. Possible causes may include a worn stock rail or damaged / worn brass plunger.

    NOTE If the tappet screw is unscrewed more than the 17 mm maximum to compensate for worn components it may become detached from the cam shaft.
    Renewal of the brass plunger is described in the next section.
    Return to DETECTION TEST VCC DETECTOR TEST (NR/SMS/Test/007).

3.3 Renewing the Brass Plunger

1. Disconnect CMA 24 cable connector in junction box. *(If applicable).*
2. Set the point machine selector lever to *'Hand'*.
3. Remove the VCC cover.
4. Remove the detector cover.
5. Manually operate the points to open the switch blade on the side to be fitted *(if applicable).*
6. Check detector finger is in pre-engagement notch. *(Switch open position, Figure 3).*

Figure 3

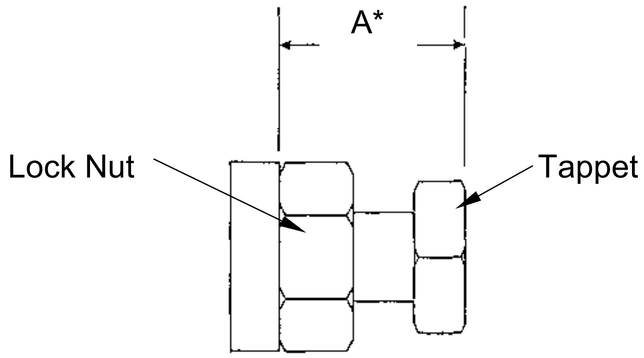
7. Remove detector from VCC lock body.
8. Remove plunger.
   (Dispose of in accordance with local instructions).
9. Insert plunger gauge into hollow bolt.
10. Re-fit detector.
    (2 screws in opposite corners sufficient).
11. Set tappet screw one to two turns out.
    *(Do **NOT** tighten lock nut).*
12. Lever the finger open and insert 6 mm gauge.
    *(Do **NOT** lever against plunger gauge adjusting screw. Insert screw driver behind finger pointing downwards towards pre-engagement notch with blade against base of terminal block to prevent damaging the plastic body, Figure 4).*

Figure 4

13. Slowly close and lock the switch.
    (Checking that the finger engages with the slot in the crank head).
14. Unscrew plunger gauge adjusting screw until it makes contact with head of tappet screw.
15. Unlock and open the switch.
16. Insert screwdriver to prevent finger springing back. *(Figure 4).*
17. Remove the 6 mm gauge whilst easing the finger into the pre-engagement notch.
18. Remove detector.
19. Remove plunger gauge without adjusting it.
20. Mark gauged length onto new plunger. Figure 5.

Figure 5

21. Cut plunger to plunger gauge length.
22. Insert plunger.
23. Re-fit and secure detector *(4 screws).*
24. Close and lock points.
    (Checking finger engages with slot in crank head).
25. Adjust detection tappet screw until 6 mm gauge is a sliding fit.
26. Open switch and tighten tappet screw lock nut.
27. Close and lock points. Re-check detector operation with 6 mm gauge.
28. *Measure* the overall length of the tappet screw and lock nut assembly.
    (dimension 'A' – Figure 6).



*Note: Maximum permitted length 17mm.

Figure 6

29. *Check* all fixings are secure.
30. *Lubricate* cam shaft. (NR/SMS/PC61).
31. Manually operate the points (over and back).
32. *Check* that the detector and lock operate correctly.
33. Refit the detector cover.
34. Refit the VCC cover and secure with the spring clips and RKB221 padlock.
35. Re-connect CMA 24 cable connector in junction box. *(If applicable).*
36. *FACING POINT LOCK TEST (NR/SMS/Test/005).*
    DETECTION TEST VCC DETECTOR TEST (NR/SMS/Test/007).

3.4 Procedure Following a 'Run-through'

To prevent damage to the VCC lock assembly in the event of a run through the crank lock arm has been designed to fail. The mode of failure will be by bowing, either concave or convex according to whether the associated switch rail was open or closed.

If a run through is suspected, examine the 'C' portion of the crank lock arm for each lie of points. An obvious gap between the 'C' heel and the switch rail shim pack when the associated switch rail is closed and locked will indicate a run through has probably occurred. In addition to the probable deformation of the 'C' arm, it is likely the detector contacts and "finger" will have become distorted – see Detector Mechanism section of this document if a run through has occurred.

To confirm the occurrence of a run through the crank lock assembly should be removed and the lock arm checked for distortion by placing it on a flat surface.

If the lock arm is found to be distorted, either concave or convex, then a run through has occurred and **both** lock crank assemblies shall be replaced along with a thorough examination and possible replacement of the detector mechanism.

The damaged lock crank assemblies and any elements of damaged detectors shall be destroyed to prevent accidental re-use.

If a run through has occurred the coupling and / or drive rods may have been distorted and other point equipment and fittings damaged.

Inform your SM (S) so that the necessary inspection and remedial action can be arranged.

3.5 Replacement of the Printed Circuit Board (PCB) in an Ansaldo T72 Point Machine Junction Box

- Isolate point machine *(disconnect CMA 24 cable plug coupler from junction box PCB).*
- Isolate junction box PCB, point machine heater supply cable (2 core), point control/detection cable (3 core).
- Note wire number and corresponding terminal block identity for the point machine heater supply also point control and detection.
- Unplug plug couplers and dummy plug coupler(s) if fitted.
- Disconnect point heater supply also point control and detection wires from respective terminal blocks.
- Carefully remove PCB assembly from junction box (retain fixings).
- Carefully install new PCB assembly in junction box and secure. *(Retain packaging for salvaged PCB).*
- Re-connect CMA 24 cable plug coupler.
- Re-connect plug couplers and dummy plug coupler(s) if applicable.
- Refit point heater supply and point control and detection wires in respective terminal block connections.
- Protect salvaged PCB with suitable packaging and return to the MSSCC for refurbishment.

3.6 Sources of Additional Information

The information contained within the maintenance specifications was sourced from the following documents. They may be used as a source of additional information.

Manufacturer's design changes may supersede the information contained within the documents listed below.

  (1st October 2001 Edition)

4 SD321 COLOUR LIGHT SIGNAL

The last function of maintenance is to test and observe that the equipment operates correctly from the controlling point.

Signal lamp voltage and proving tests shall not be carried out if a train is approaching as this may cause the displayed aspect to change from the lower to the upper unit.

4.1 SD321 Signal Details

4.1.1 Development

The SD 321 signal used with the Ansaldo ACC system has three aspects displayed from a single aperture which are operated and proved alight over a single pair of wires.

A signal head consists of two light units, each consisting of an optical assembly and an electrical filter unit. They are connected by a plug coupler and short cable.

The optical assembly contains 3 halogen lamps, one for the red aspect, one for the yellow and one for the green. Each lamp is mounted in a removable lamp holder. The optical assembly is sealed. It contains three filters, two dichroic mirrors and a lens. It is secured into the signal head by three bolts.

A dichroic mirror reflects light of one colour but allows light of other colours to pass through. The three light sources are mounted at right angles to each other.

The light from the red lamp passes straight though a red filter and then through the yellow and green dichroic mirrors.

The yellow light (from the top lamp) passes though a yellow filter and is reflected into the lens by the yellow dichroic mirror after passing through the green dichroic mirror.

The green light (from the bottom lamp) passes though a green filter and is reflected into the lens by the green dichroic mirror.

In the horizontal plane, the beam is slightly wider than a conventional signal but the beam is very narrow in the vertical plane. Correct adjustment of the signal head is therefore critical in the vertical plane.

4.1.2 Degraded modes

As each lamp is fitted with only a single filament, when a lamp fails, it cannot revert to an auxiliary filament. The failure of a lamp in one optical unit will cause a switch over to the other unit. The degraded mode 'corresponding auxiliary aspect' will be displayed.

If a train has passed the previous signal when a lamp failure occurs, then a more restrictive aspect may be displayed.

The normal aspects and degraded modes are shown below.

Aspect	Normal Aspect	Corresponding Auxiliary Aspect	Aspect Type
Red	Bottom red	Top red (previous signal at red)	2, 3 & 4
Yellow	Bottom yellow	Top yellow	2, 3 & 4
Double yellow	Top and bottom yellow	Top or bottom yellow (previous signal at double yellow)	4
Flashing yellow (single)	Bottom yellow	Top yellow (steady) **OR** Top yellow (flashing) see note below.	2, 3 & 4
Green	Top green	Bottom green	2, 3 & 4
Flashing yellow (double)	Top and bottom yellow	Top or bottom yellow (steady)	4

The flashing yellow auxiliary aspect is only available if the main flashing yellow aspect was already declared failed when a flashing yellow aspect is commanded to be displayed <u>and</u> there is no train approaching.

4.1.3 Failure of Corresponding Auxiliary Aspect

In the event that a corresponding auxiliary lamp should fail before the 'normally lit' lamp can be replaced then the next most restrictive aspect will be displayed.

4.1.4 Signal Lamp

The lamp is mounted in a holder which is secured to the optical unit with a bayonet type connection which also provides connection to the power supply.

The use of the correct lamp is vital to the performance of the signal. To produce light of the correct colour and intensity, the GE type M47 12 volt halogen lamp shall be used**.**

4.1.5 Signal Lamp Voltage

The signal lamp voltage shall be set to operate within the range **11.6** volts to **12.2** volts ac.

4.1.6 Maintaining the Specified Voltage Range

The lamp voltage cannot be adjusted at the signal head other than by means of adjusting the transformer in the lineside location case. However, this only provides a coarse form of adjustment. The lamp operating voltage is set up at installation and the control equipment maintains this voltage.

The set up voltage includes allowance for the length and type of cable feeding the signal. This is referred to as the ‘C – parameter’. If the cable is repaired or replaced, the lamp voltage shall be checked. If it is incorrect, the voltage parameters for the signal may need adjusting. This requires a data change, which currently has to be done by the manufacturer (Ansaldo), and a full re-test.

Conversely if the lamp voltage is found to be incorrect then the cable details, length, type, core size etc. shall be checked for compliance with the site drawings.

It is emphasised that any cable replacement shall be ‘like for like’.

Similarly cable repair shall not result in degradation of the original set up parameters.

On completion of the repair the lamp voltage shall be checked as follows:

(a) Check the lamp voltage of the most restrictive aspect is not less than 11.6V

then

(b) Check the lamp voltage of the normally lit aspect is not more than 12.2V (signals subject to the signallers extensive use of the auto-working facility should also be considered), i.e. predominant aspect displayed – green and not red.

The voltage is preset in the ACC and cannot be altered and should never require adjustment for maintenance purposes.

If the correct voltage cannot be maintained, report the problem to your SM(S) immediately.

4.1.7 Voltage on an Unlit Signal Lamp

If the voltage on any unlit lamp exceeds 0.8 volts report the situation to your SM(S) immediately.

A possible cause may be a faulty power supply unit. The unit cannot be serviced on site and should be replaced.

4.1.8 Signal Lamp Power Supply

All SDO signals are fed by POT / LAP circuits, with the exception of signals used to control the Cheadle Junction, Adswood Road, and the Macclesfield line. These signals are fed from PLS: 01, 51, 51A, 52, and 53 by POT / CLAM circuits.

4.1.9 Service Replacement

The GE type M47 12 volt halogen lamp is the only acceptable service replacement lamp.

Check that sufficient spare lamps are readily available.

If the lamp has recently been illuminated, the envelope and some metal components of the lamp holder will be very hot.

When changing the lamp take precautions to keep the lamp envelope clean, see *'Caution'* below.

The lamp shall be pushed completely into the lamp holder and shall be upright in the holder. Failure to do so may cause the beam to be out of alignment by up to 1.5° in the vertical plane.

Misalignment of the lamp can lead to the signal appearing dim when viewed from a train and in certain circumstances, when viewed off axis and close up; the signal may appear slightly discoloured.

It is therefore extremely important that after replacing a lamp, the colour of the particular aspect is checked from a position adjacent to where a train would normally stop.

If the signal appears discoloured re-check the lamp fitting and alignment and repeat the lineside check.

When replacing a lamp holder, the red notch on the lamp holder should align with the red notch on the optical assembly to check correct polarisation.

This lamp replacement procedure is described below:

- Turn the lamp holder counter-clockwise to release / remove the holder
- Remove the lamp
- Insert both pins of the new lamp into the sockets of the lamp holder
- Push the lamp firmly into its seat. Take care to avoid bending the pins
- Check the lamp is centred relative to the lamp holder. This is to check correct focusing of the optical system and the required visibility
- Align the red notches and re-insert the lamp holder

- Turn the lamp holder clockwise until locked
- Check that the lamp illuminates correctly

The glass envelope of a signal lamp, especially a halogen lamp, shall not be touched with bare hands because the skin's natural oils will cause the glass to blacken when the lamp gets hot. The light output will be reduced. Always use tissue paper or similar clean material when handling a signal lamp.

If the lamp becomes contaminated, clean it with methylated spirit.

4.1.10 Signal Lamp Failure Mode

An apparently 'healthy' lamp was found to be the cause of an intermittent signal failure. This incident has revealed that this type of lamp may fail intermittently prior to total failure. It is recommended that lamp substitution is considered as the first option when rectifying a similar fault. Recovered lamps shall be disposed of in accordance with local instructions to prevent accidental re-use which could result in a similar failure elsewhere and / or invalidate the lamp life monitoring data.

4.1.11 Replacement – Frequency

The GE type M47 12 volt halogen lamp has a rated life of 2000 hours when run at 12.0 volts as specified to check optimum luminance and aspect colour.

The lamp shall be changed when the aggregate operational hours are within 1750 and 1800 hours.

The actual period over which the hours are accrued will vary according to the typical daily operation of the signal and the usual aspect displayed.

To enable a robust and effective replacement schedule to be maintained, the operational life of each lamp in the signal head assembly is monitored. Therefore when a signal lamp is replaced, the MSSCC Box Technician shall be informed to enable the particular lamp life counter to be reset to zero ('no hours'). The ONLD PC at the Maintenance Desk in the MSSCC is used to extract and review this data. For further information refer to the Manchester South Signalling System O&M manuals.

4.1.12 Dispersing Lens

The dispersing lens (outer lens) spreads the light from the lens so as to provide the desired beam shape. There are three types of lens available for the SD 321 signal. Type 'A' (the 'standard') lens, type 'Bd' and type 'Bs'. The lens type is indicated by a small 'A' or 'Bd' or 'Bs' adjacent to the lens locating lug / nib on the rim at the bottom of the lens.

The type 'Bd' lens spreads the light to the right of the signal axis - 'd' (destro – right).

The type 'Bs' lens spreads the light to the left of the signal axis - 's' (sinistro – left).

The direction of the light spread is also indicated by a small arrow adjacent to the 'Bd' or 'Bs' identification. .

The majority of UK signals are fitted with the type 'A' lens.

It is important that the correct lens is fitted or the signal beam will not be aligned as specified on the signal head record card or sighting form. The beam produced by the lens will also be different.

The lens type and orientation marking is obscured by the lens retaining ring when mounted in the signal head.

4.1.13 Hot Strip

Unlike the lenses fitted to typical colour light signals the 'hot strip' is at the **top** of the lens and directs part of the beam downwards. The position of the lens is fixed by the small locating lug / nib engaging a slot in the lens retaining ring. The ring is secured by five screws arranged in a pattern to check correct orientation. Consequently the position of the 'hot strip' is not adjustable to operate at different angles.

4.1.14 Lens Replacement

Check that when replacing a dispersing lens that the small locating lug / nib on the rim at the bottom of the lens engages the **correct** slot in the lens retaining ring.

The centre slot is marked 'A' and is used for type 'A' lenses. The adjacent slots are marked 'Bd' and 'Bs' as appropriate. The locating lug / nib of the type 'Bd' lens shall be inserted in the slot marked 'Bd'. The locating lug / nib of the type 'Bs' lens shall be inserted in the slot marked 'Bs'.

Unless correctly seated, the lens will be mis-aligned reducing light output in the required direction.

4.1.15 Hood Replacement

There are three types of hood fitted to the SDO type signal. Each hood has been designed to check the optimum performance from the particular dispersing lens.

It is extremely important that the correct hood is fitted in conjunction with the particular lens type. For further details refer to 'Service Replacements (Signal Head Assembly)'.

4.1.16 Lens Cleaning

External
The external surface of the dispersing lens should be cleaned with a clean soft cloth dampened with water or similar non abrasive cleaning agent to remove dust and grime.

Internal
If it becomes necessary to clean the internal surface of the dispersing lens the optical unit will have to be removed. The method of cleaning is the same as for the external surface.

The reflectors and dichroic filters are sealed within the optical unit, and do not require any maintenance procedures.

To reduce the ingress of insects, dust, smoke or similar contaminants check that the door seal is in good condition. Arrange replacement if damaged or missing.

4.1.17 Signal Light Beam Alignment

Always refer to the signal head record card for the signal alignment details. If the details are not available or clarification is required, report it to your SM (S).

In the case of the 'Bd' and 'Bs' lens the alignment device does not align with the centre of the beam. The designated alignment point is specified at site and does not represent the point at which the signal will appear at its brightest.

The alignment procedure for the SD 321 signal is different to that used for other types of colour light signal.

The alignment device is a small portable telescope which is only fitted to the signal head for the duration of the alignment procedure. This permits use at other sites as necessary.

The signal head can be aligned by adjusting the nuts on the four M16 studs securing the signal head to the base plate. Four slotted holes in the base plate permit limited lateral rotation.

Because of the narrowness of the beam in the vertical plane, care should be taken to check that the signal head is correctly aligned.

The signal head is aligned as follows:

- Fit the small telescope to the two supports on the left side of the housing
- Raise the panel obscuring the corresponding hole in the background
- Adjust the signal head to align the centre of the cross on the alignment point
- Tighten the nuts and lock nuts on the four M16 base plate studs
- Tighten the nuts on the four M20 bolts securing the base plate to the post
- Check that the signal head is still aligned on the alignment point
- Remove the telescope
- Lower the obscuring panel
- Close and secure the access door

Check that the telescope is protected from damage during storage.

4.2 Item Replacement Procedures

4.2.1 Optical Unit

- Disconnect the plug coupler.
- Unscrew the M5 screw securing the lower lug of the unit.
- Unscrew the two M10 captive screws securing the side lugs of the unit.

- Remove the unit.
- Install the replacement unit into the aperture and firmly tighten the two M10 captive screws.
- Re-fit and tighten the M5 screw to check that optical unit is firmly locked in place.
- Reconnect the plug coupler.
- Confirm correct operation.

4.2.2 Filter / Power Supply Unit

- Remove the two ‘U’ links (power supply connection).
- Disconnect the earth connection.
- Disconnect the plug coupler.
- Unscrew the lower two knurled fixing nuts.
- Slide unit out of the signal head.
- Slide the replacement unit into position.
- Re-fit and tighten the lower two knurled fixing nuts.
- Reconnect the earth connection.
- Reconnect the plug coupler.
- Re-fit the two ‘U’ links (power supply connection).
- Confirm correct operation.

4.3 Construction Details

4.3.1 Signal Head Assembly Service Replacements

Component	Ansaldo Signal Part number
Housing assembly comprises: Housing Lower fixing / adjustment flange Cable terminal board Dispersing lenses type ‘A’ Hoods (compatible with lens) Background (1120 x 600mm)	P21B.000006
Housing assembly as above Dispersing lenses type ‘Bs’	P21B.000007
Housing assembly as above Dispersing lenses type ‘Bd’	P21B.000008

Hood (Signal fitted with a type 'A' lens)	109E.A29003
Hood *(Signal fitted with a type 'Bd' lens)*	109E.A29018
Hood (Signal fitted with a type 'Bs' lens)	109E.A29019
Dispersing lens (type 'A') (Standard lens)	2/993117
Dispersing lens (type 'Bs') (Where specified on site record card or sighting form)	2/993118
Dispersing lens (type 'Bd') (Where specified on site record card or sighting form)	2/993119
Optical unit	P21B.000003
Filter / Power supply unit	P31B.000001

4.3.2 Signal Lamp Service Replacement

Component	GEC Part number
12 volt halogen lamp	GE type M47

4.3.3 Fixings

Four slotted holes in flange (M20 bolts) – (typical signal head fixing / adjustment flange)

4.3.4 Weight

A complete signal assembly comprises of:

A housing unit: 58 Kg (approx.)

2 x Optical unit 7Kg (3.5 Kg each)*

2 x Filter unit 11Kg (5.5 Kg each)*

This makes a total weight of the signal assembly of approximately 76 Kg.

*The optical units and filter units are usually fitted after the housing unit has been fixed to the post or gantry.

4.3.5 Special Tools

Tools required in addition to the standard toolkit.

Component	Ansaldo Signal Part Number
Signal alignment telescope	109E.A29015

4.4 Ancillary Signals

These consist of the following:

- Position Light Junction Indicator (PLJI)
- Position Light Signal (PLS)
- Ground Position Light Signal (GPLS)
- Banner
- OFF Indicator

4.4.1 The Basic Lamp Driving Circuit

Each lamp (or pair of lamps for a PLJI) is driven directly by a POT (via a CLAM) over a 2-core cable, the maximum output of the POT being 60W. The POT provides the lamp feed and lamp proving.

The POT/CLAM combination produces a feed at 200 volts at a frequency of 250Hz. This is stepped down to 110 volts at an intermediate apparatus case. This then feeds to the transformer in the signal where it is transformed to 12 volts.

The POT provides a carefully regulated supply for the lamp and monitors that the current flowing is between pre-set limits. In the event of the lamp failing, its POT recognises that the current has fallen to nearly zero (a small amount of current still flows through the transformers). The POT then shuts down its output and provides an alarm to the signaller and MSSCC Box Technician.

The signal units and associated lamp details are shown below:

Unit	Lamps	Number of POTs	Rated Life (Hours)
PLJI	5 x 12V 24W SL35 2 pairs in parallel and 1 pivot	2 per route and 1 for pivot	Standard 2000 Long life 8000
GPL	3 x 10V 50W halogen (2 ON, 1 OFF)	3 (2 ON, 1 OFF)	6000
PLS	1 x 10V 50W halogen (1 OFF)	1 (1 OFF)	6000
Banner	3 x 12V 55W halogen (2 ON, 1 OFF)	3 (2 ON, 1 OFF)	1000

The rated life is dependant on the lamp being operated at the specified voltage.

4.4.2 Position Light Junction Indicator

The PLJI used in the Ansaldo ACC signalling system is optically similar with conventional PLJIs and uses the same SL35 lamps. The differences are in the internal wiring and the transformers provided.

To light a junction indicator requires three POTs, one for the pivot lamp and two POTs each driving two lamps wired in parallel. Lamps 1 and 3 are paired as are lamps 2 and 4.

The current sensing limits are set differently for the POT feeding the pivot to the other two POTs. Those feeding the junction arm lamps will detect the current falling below that required for two lamps but is more than that required to feed one lamp. It can thus detect a single lamp failure and shut down. The other lamp of the pair will be switched off. The POT feeding the pivot will detect when the current falls below that required to light one lamp and will switch off the feed to that lamp.

With a single POT shut down, there are at least 3 lamps lit so the signal is allowed to clear. If it is the pivot lamp that has failed, 4 lamps remain lit. Should a further lamp fail, this will shut down an additional POT. With 2 POTs shut down, the signal is prevented from clearing.

The PLJI transformers are of toroidal design. In the case of the single arm PLJI there is insufficient room for the three transformers and so theses are accommodated within a separate enclosure mounted within 5 metres of the PLJI with cabling between.

4.4.3 Position Light Signal

The PLS used in the Ansaldo ACC signalling system is optically and electrically similar to the fibre optic PLS and uses the same 10 volt 50 watt halogen lamps.

Normally a PLS is provided with a main and standby lamp, the auxiliary being switched in when the main lamp fails. Because of the relatively low usage of the OFF indication and the hours lit being monitored by the system, only a single lamp is provided. The lamp can be replaced after a specified number of hours before failure is likely.

The PLS unit is a standard fibre optic unit but with the auxiliary lamp and lamp proving relay omitted.

4.4.4 Ground Position Light Signal

The GPLS used in the Ansaldo ACC signalling system is optically similar to the fibre optic GPLS and uses the same 10 volt 50 watt halogen lamps. The differences are in the internal wiring and the transformers provided.

Normally a GPLS is provided with a main and standby lamp for both ON and OFF aspects, the auxiliary being switched in when the main lamp fails. Because of the low usage of the OFF indication and the hours lit being monitored by the system, only a single lamp is provided for the OFF indication. Main and auxiliary ON lamps are provided. The unit is wired differently to a standard unit. It is provided with three transformers (one per lamp) instead of the usual two.

The GPLS is directly fed by 3 POTs (via CLAMs). POTs are provided for the Main ON lamp, the Auxiliary ON lamp and the (Main) OFF lamp. Failure of the Main ON lamp will cause the Auxiliary ON lamp to light. Failure of the OFF lamp to light will cause an ON lamp to light so that the signal is not blacked out.

4.4.5 Banner Signal

The Banner Signal used in the Ansaldo ACC signalling system is optically and electrically similar to the fibre optic Banner and uses the same 12 volt 55 watt halogen lamps. Two ON lamps and one OFF lamp are provided.

4.4.6 OFF Indicator

The OFF Indicator used in the Ansaldo ACC signalling system is optically and electrically similar to the fibre optic OFF Indicator and uses the same 12 volt 55 watt halogen lamp.

4.4.7 Signal Lamp Replacement (PLJI)

The life of each signal lamp is monitored, consequently it is essential that if one of the non-pivot lamps is replaced then the other lamp fed from the same POT shall be replaced and the MSSCC Box Technician informed so that the lamp life counter for that particular circuit can be reset to zero (‘no hours’). Similarly, if the pivot lamp is replaced the MSSCC Box Technician shall be informed to enable that particular counter to be reset to zero. For further information refer to the O & M manuals.

4.4.8 Signal Lamp Replacement (PLS and GPLS)

When a lamp is replaced the MSSCC Box Technician shall be informed to enable that particular lamp life counter to be reset to zero. For further information refer to the O & M manuals.

5 CABLE MAINTENANCE

A safe system of work shall be agreed and implemented before any work is undertaken. The safe system of work may be by local directive.

Signal control cables, track circuit feed cables and apparatus case power supply cables operate at 230 volts. Before working on a cable, the cable shall be isolated at the Peripheral Location and steps taken to check that power cannot be re-connected before work is complete. (details can be found in NR/SMS/EL00).

Prior to working on any lineside circuit(s) check it is isolated and the MSSCC Box Technician made aware of the isolation.

Do not rely on the Field Device Controller disconnection switch alone to provide circuit isolation. Remove (and retain) the relevant ‘U’ link from the back of the unit or, where provided, slip the appropriate 2BA terminal link.

Do not rely on SW(2) or SW(3) disconnection switches alone to provide circuit isolation.

Isolate and lock S1 to isolate supplies to both SW(2) and SW(3).

5.1 Cables

Cables fall into one of five categories comprising: Monitored Cables, VIO Fed Cables, Non-Monitored Cables, Signal Control Tail Cables, and Other Tail Cables.

5.1.1 Monitored Cables

Signal Control Cables (ACC SIM PC monitored)

LAPS fed signals – Normally between the LAPS in the Peripheral Post and the filter in the signal head.

CLAM fed signals (only applies to signals fed from PLSs 01, 11, 51, 51A, 52 and 53) - Normally between the CLAM in the Peripheral Post and the step down transformer in the signal location.

In the rare cases where an isolation transformer is provided if the cable length exceeds 1300 metres, the monitored cable is between the CLAM in the Peripheral Post and the isolation transformer.

Point Control Cables (ACC SIM PC monitored)

All cables associated with point control and detection between the C-DEV in the Peripheral Post and the point junction box.

Track Circuit Cables (ACC SIM PC monitored)

The cables between the CTRC in the Peripheral Post and the step down transformer feeding the track feed unit (referred to as the Track Feed cables).

The detection and diagnostic cables between the track circuit relay/ICDR and the CTRC in the Peripheral Post (referred to as the Track Relay cables).

Power cables (SCADA Monitored)

Power cables connected to the SECAP 230 V power supplies between the Peripheral Location (PL) and apparatus cases, supplying the power for equipment such as AWS, TPWS, location heaters and lighting etc. are monitored by the in-built ELDs within the SECAP units. The alarms from these units are collected on the SCADA system and displayed on the SCADA terminal on the MSSCC Box Technicians desk.

5.1.2 Non-Monitored Cables

Indication cables

All VIO cables (control and indication) including:

Cables between the VIO or Terminal Board Rack in the Peripheral Post and the relay in the location case for equipment such as AWS and TPWS. The cables between the location case for equipment and the VIO or Terminal Board Rack in the Peripheral Post indicating the state of TPWS.

Multicore Cables

Multicore Cables between the Terminal Board Rack in the Peripheral Posts and the Fringe Boxes.

Signal Control Tail Cables

LAPS fed signals**;** not applicable.

CLAM fed signals (only applies to signals fed from PLS 01, 11, 51, 51A, 52 and 53),

The cables between the isolation transformer and step down transformer (where an isolation transformer is provided) and between the step down transformer and the filter unit in the signal head.

Track Circuit Tail Cables

The cables between the location case and lineside disconnection boxes and/or rails.

Other Tail Cables

The cables between the location case and equipment such as AWS, TPWS, etc.

5.2 Insulation Integrity Testing

5.2.1 Monitored Cables - ACC

These cables are continuously monitored by the ACC equipment. Should the leakage to earth exceed a pre-set level, an alarm is produced.

As set, the system will report the cable condition. If the cable resistance is greater than 5000kOhm, the Diagnostic Console will display **'Rd: > 5.0M'** with a status of **'Insulation OK'**.

If the resistance is between 5000kΩ and 1000kΩ, the actual value is displayed e.g. *1732K* with a status of **'Insulation OK'**.

If the resistance is less than 1000kOhm, the actual value is displayed, e.g. *135K* with a status of **'Insulation Error! <->'**.

Periodically, a record should be made of the actual values for earth leakage as measured by the monitoring equipment where these are less than 5000kΩ so that trends can be detected.

5.2.2 Monitored Cables - SCADA

Treat power cables as any other cable fitted with ELD.
High voltages are present on power cables, the appropriate precautions for working on high voltage equipment shall be implemented and observed (see NR/SMS/EL00).

5.3 Earth Monitoring Integrity Testing - ACC

This tests that the ACC's integral earth monitoring system is working correctly. The method of testing is described in NR/SMS/Test/171.

5.3.1 Equipment

The following equipment is required:

A calibrated resistance decade box with 'flying leads' that can be clipped to the Earth Bus-Bar (or similar suitable earth point) and inserted in to the 'test hole' on the 'U-Link' (see below).

Each 'U-Link' is provided with a 'test hole' in its insulation to enable the circuit to be tested without the need to partially withdraw the link thereby risking circuit interruption.

The actual circuits to be tested are detailed in the O&M manuals for the system.

5.3.2 Resources

Personnel will be required at the Peripheral Post and at the MSSCC as described below.

Peripheral Post: – to undertake the tests and to record the resistance shown on the CNT diagnostic screen section of the SIM PC (alternatively this can be viewed from the SIM PC on the "on-line" diagnostic terminal located on the Maintainers Operating Terminal in the MSSCC).

MSSCC: – to observe that the alarm is displayed on the Maintainers Operating Terminal.

5.3.3 Records

A list of the circuits tested, and a log of the test results shall be kept.

5.4 Monitored Cables – SECAP Insulation Monitor

The integrity of the signal power cable insulation is monitored by the Earth Leakage Detectors (ELDs) contained within the SECAP 230 volt power supply units fitted in the Peripheral Location. Each unit contains an integral audible alarm and LEDS which indicate the severity of the earth fault (local monitoring).
An alarm message will be displayed on the SCADA terminal on the MSSCC Box Technicians desk when the earth resistance drops below 5000k Ohm.
A typical message format is:
'North West Zone Manchester South – Middlewich South – REB 91 - PL 91 ELD FAILURE ALARM '

Earth alarms are to be investigated with on-site attendance at the earliest opportunity.

5.4.1 Non-Monitored Cables – Earth testing

V10 Fed Circuits:
These cables should be dealt with as any other tail cable connected to similar equipment, see NR/SMS/Test/051

Signal Control Tail Cables
These cables should be treated as any other tail cable and should be tested as specified in NR/SMS/Test/054

Track Circuit Tail Cables
These cables should be dealt with as any track circuit tail cable

Other Tail Cables
These cables should be dealt with as any other tail cable connected to similar equipment see NR/SMS/Test/051

5.5 Corrective Maintenance on Cables

5.5.1 Monitored, VIO Fed (Control), Signal Control Tail Cables and Power Cables

The cabling differs from conventional signalling in that most cables are two core rather than multicore and the distances between disconnection points are much greater. Different techniques are therefore required for fault location.

Earth faults on these types of cable shall be located and repaired promptly. The system can tolerate a single fault. Such a fault shall be removed before a second fault occurs at a different point on the cable. This allows, in normal circumstances, up to two weeks for remedial action.

As the monitoring system can cover groups of cables, the actual defective cable shall be localised.

Testing with the 1000 volt insulation tester will escalate the breakdown of defective cable insulation thereby reducing the time scale for remedial action.

Cables showing values between 5000kΩ and 1000kΩ

- The specific defective cable should be identified and tested within four weeks (maximum).
- The defective cable should be regularly monitored and remedial action agreed with the SM (S).

Monitored cables showing values between 1000kΩ and 100kΩ inclusive

- The S&TME shall authorise retention in service and manage the repair within two weeks (maximum).
- The Route Asset Manager (Signals) shall be advised of the situation as soon as practicable.
- All actions taken shall be recorded.
- The insulation resistance of any cable in this insulation range shall be re-checked every 24 hours.

- The insulation resistance values shall be recorded to enable the rate of degradation to be assessed.

If the rate of degradation increases rapidly the S&TME shall be informed and urgent remedial action taken.

The S&TME authority to retain in service is extended down to 100kΩ.

Cables showing values below 100kΩ (except track circuit feed circuits)

- The Route Asset Manager (Signals) has the discretion to retain in service.
- There will be no need to sign out of use in this range pending this permission.
- The defective cable should not be allowed to remain in service for more than two weeks (maximum).
- During this period the insulation resistance value of the affected circuit shall be checked and recorded on every shift to enable the rate of degradation to be assessed.

If the rate of degradation increases rapidly the S&TME shall be informed and urgent remedial action taken.

Track circuit feed cables showing values at or below 50kOhm

- The affected circuit shall be repaired within 2 days, if this is not possible:
- The signaller will invoke GE/RT8000 Rule Book Module TS2 'Track circuit block regulations' - Section 10 – 'Failure of signalling equipment' until such time as the failure is repaired.

With the proposed method of testing, there is a risk that an earth fault may be present and undiscovered for some time. Any earth fault discovered shall be promptly located and repaired.

The location of a fault might require the use of a Time Domain Reflectometer. Once localised it is necessary to identify at site which cable is the one in question.

Spare cables have not been provided so there is no easy means of cable diversion available. Any substitute cable used shall be of the same conductor size and length as the defective cable. Any cable inserted as part of a repair shall be of the same conductor size and length as the cable it replaces.

Cable jointing techniques are the same as for normal signalling cables.

Before re-commissioning a previously defective circuit, the requirements of SMTH shall be followed.

A particular hazard is that of cables being connected to the wrong function. A crossed cable may cause a wrong signal to show a proceed aspect. Where more than one cable is cut, it is essential that it is positively established that the correct cables are being rejoined.

Track Circuit Tail Cables

These are repaired, tested, and re-commissioned in the appropriate way for that type of conventional equipment.

Other Tail Cables

These are repaired, tested, and re-commissioned in the appropriate way for that type of conventional equipment.

Service Replacement

For details of replacement components refer to section 11.

6 CONTROL ROOM EQUIPMENT

6.1 Display System

6.1.1 Rear Projection Display System

The image displayed on the rear projection cube screens (wall display) is produced by a GraphXMaster Projector. To promote optimum performance of the projector the optical system shall be kept scrupulously clean, preferably by keeping invasive maintenance to the absolute minimum.

Personal protective equipment will be required when servicing this apparatus, especially when handling the lamp.

6.1.2 GraphXMaster Projector

High voltages are present in the projector.

When performing any service on this equipment, precautions for working on high voltage equipment shall be implemented and observed.

An AC leakage test shall be performed on completion of any service to check the equipment is safe to operate.

A 500 volt dc Insulation Tester is required; the test is detailed in NR/SMS/Test/173.

For further information see GraphXMaster Service Manual - 54-017145-02P - section 2.3 General Guidelines – AC Leakage Test – Cold Check.

6.1.3 Electro Static Sensitive Devices (ESSDs)

ESSDs are installed in this equipment. Electro Static Sensitive precautions shall be taken during all servicing of this equipment.

6.1.4 Projector Lamp

The lamp used in the ‘GraphXMaster’ projector is a 100W Ultra High Pressure (UHP) lamp which produces an intense source of light and heat. The lamp should be enclosed during operation and shall be treated with care.

Never look directly into the lens of the projector. The brilliant light emitted may cause permanent damage to your eyes.

The ultra-violet light generated by the lamp can have the same effect on the skin and the eyes as sunlight. Wear ultra-violet protective goggles with side guards when servicing the lamp.

6.1.5 Ventilation

To check that the lamp and projector do not overheat the ventilation slots shall not be obstructed.

6.2 Lamp Replacement in the GraphXMaster Projector

6.2.1 Aggregate Hours

The aggregate operational hours of the lamp are monitored by the system software and can be ascertained by pressing the 'Display' key on the keypad.

It is recommended that the lamp should be changed when its aggregate operational hours total 6000. If the lamp is used in excess of 6000 hours the risk of the lamp shattering is increased as a result of changes in the quartz glass.

Never remove the lamp from its housing immediately after it has been powered down. The lamp is under great pressure when hot and may explode causing personal injury and / or property damage.

6.2.2 Precautions

After turning off the projector wait at least 20 minutes before unplugging it to allow sufficient time for the internal fans to cool the lamp and for the projector to automatically turn off. The fans will shut off when the lamp has cooled sufficiently.

The lamp shall be allowed to cool for at least 1 hour before removing it from the lamp compartment.

When replacing the lamp, do not touch the sapphire (glass) surface of the lamp otherwise the output will be seriously degraded. Intense heat (hotspots) can occur where fingerprints are left and could cause the lamp to explode.

If the surface is accidentally touched it shall be cleaned with a lint-free cloth moistened with isopropyl alcohol.

Always wear clean cotton gloves and protective UV goggles with side protection when handling the lamp.

6.2.3 Procedure

- Press 'POWER OFF' on keypad to isolate the projector.
- Wait until the fans automatically shut off.
  Approximately 20 minutes.

- Remove the 2 small panels on the rear panel to gain access to the input panel and the lamp.
  4 screws per panel.
- Turn OFF the MAIN POWER SWITCH
  Located on the input pane).
- Unplug the projector and allow the lamp to cool
  Approximately 1 hour.
- Loosen the captive screws securing lamp module.
- Pull the lamp module from its compartment using the handle provided.
  Keep the module level as it is withdrawn by supporting it underneath with your other hand.
- Slide the new lamp module into position using the handle provided.
  Keep the module level as it is inserted by supporting it underneath with your other hand).
- Check that it is fully inserted into its compartment and secure in position with the captive screws.
- Plug in the projector.
- Turn ON the MAIN POWER SWITCH.
- Replace both access panels and secure in position.

  NOTE If the lamp module is not seated properly in the compartment or the captive screws are not tightened sufficiently the lamp module will not strike and the lamp error code '**4**' will appear on the status screen.

- Reset the lamp timer to record the aggregate operating hours of the new lamp.
  Service Menu.
- *Adjust the CSC (primary colour purity).
- (Adjust CSC)
  Highly recommended.
- *Align the lamp unit.
  6-Axis Adjuster.

*: For procedure refer to GraphXMaster CX50-100U Installation and Maintenance Manual - 54-017148-02P - section 2 - Installation and Setup.

6.2.4 CSC

The function of the CSC is to adjust the actual colour of the primary colours (red, blue, and green) to achieve optimum matching between cube screens in the video wall (wall display). Adjustment may be required when a lamp is renewed. Check that sufficient time has elapsed for the new lamp to warm up before proceeding.

The quality of the primary colours may deteriorate when a lamp is nearing its maximum permitted operational life (6000 hours).

6.2.5 6-Axis Adjuster

The 6 axis adjuster comprises 4 screws and a 2 position lever. Any distortion observed in the displayed image can be corrected by adjusting the screws using the 5mm and 2 mm Allen keys provided in the User's Kit.

6.2.6 Focus

Once set, adjustment of the image focus should not be necessary. Any subsequent adjustment to counteract distortion of the projected image may require the attention of a skilled technician. The focus can be manually adjusted by turning the thumb screws on the lens barrel but is not normally required.

6.3 Cleaning

The projector shall be unplugged before cleaning.

Generally, cleaning should not be necessary and should be avoided unless absolutely essential. This is to prevent accidental contamination of the optical surfaces and subsequent degradation of the projector output.

Maintaining the cleanliness of the projector and its components during servicing is essential to the continued optimum performance of the projector.

During servicing take every precaution to avoid contaminating the optical surfaces. Fingerprints on the optical components may cause a noticeable reduction in lamp output. Wear clean cotton gloves when handling internal components.

6.3.1 Projector Lens

To avoid the risk of scratching the lens it should only be cleaned when it is absolutely necessary, i.e. degradation of the image and / or foreign bodies appearing on the wall display.

A light coating of dust will not adversely affect the quality of the image.

If cleaning is required, use a clean DRY soft cotton cloth rubbing gently in a circular motion.

6.3.2 Projector Lamp

The lamp should not require cleaning during its lifetime.

However, if the sapphire (glass) surface is accidentally touched with bare hands it shall be cleaned with a lint-free cloth moistened with isopropyl alcohol.

Finger marks or similar contamination will reduce the output of the lamp and create 'hotspots' which may cause the lamp to explode.

6.3.3 Cube Screens (Low glare and High contrast type)

Clean with a clean soft damp cloth rubbing gently in a circular motion.

6.3.4 Cube Enclosure

Clean with a clean soft damp cloth. Do not use liquid or aerosol cleaners.

6.4 Keypad, IR, and Wired Type

6.4.1 Keypad Batteries

The keypad is powered by 4 AA size alkaline batteries.

6.4.2 Battery Replacement Procedure

- Remove cover on the underside of the keypad.
  Push the small tab in and up at the same time.
- Remove old batteries.
  Dispose of in accordance with local directive(s).
- Fit the new batteries.
  The battery orientation is marked in the battery compartment.
- Refit the battery cover.
  Check the bottom edge of the cover engages the rim of the compartment before closing. An audible 'click' will indicate that the cover has been refitted correctly.

6.5 Sources of Information

For further information refer to the relevant sections of:

GraphXMaster User Manual - 54-017144-02P (© 2001).

GraphXMaster Service Manual - 54-017145-02P (© 2001).

GraphXMaster CX50-100U Installation and Maintenance Manual - 54-017148-02P (© 2001).

6.6 Ordering Service Replacements

The equipment is covered by the ACC system product approval, projector lamps (and other components) can be ordered direct from Christie.

The following details are required:

- Christie Digital System part number (each item)
- Projector model number*
- Serial number*
- Date of manufacture*

*These details are on the projector license label.

The Christie Digital System part numbers are shown in the parts index list in section 5 (Parts and Module Replacement) of the GraphXMaster Service Manual - 54-017145-02P. Exploded views of the equipment to assist identification of the components are also included.

7 MSCC System Layout - Fibre Optic Configuration

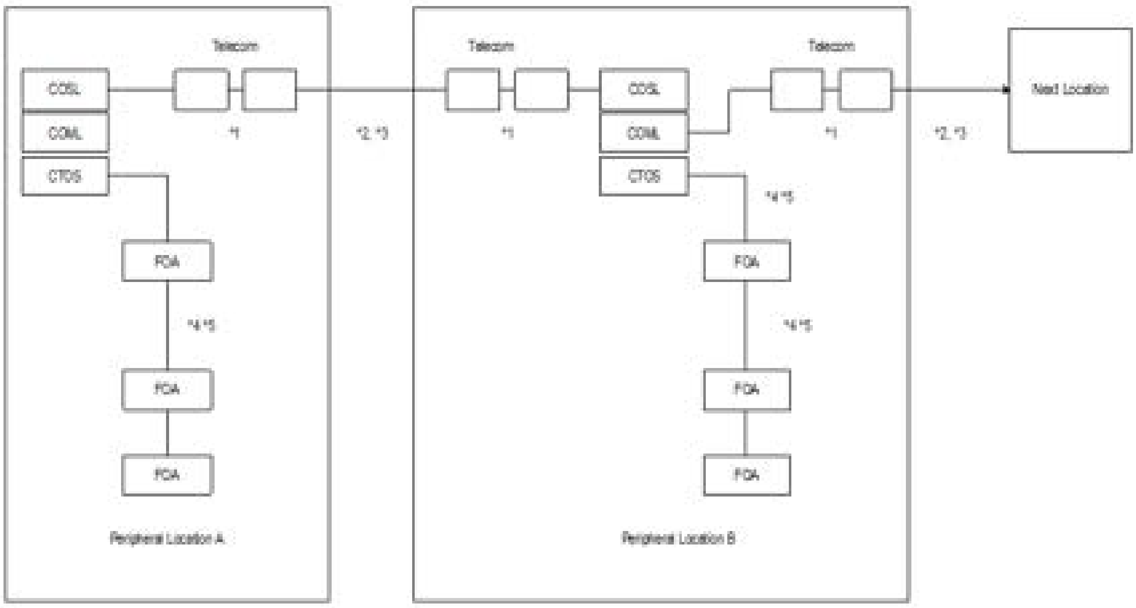
The infra-red light used for transmitting data in the fibre optic system is not visible but the intensity is sufficient to cause permanent eye damage. Do not look into the end of a fibre, nor directly into the open connectors of a fibre optic card while the card is plugged into a working system.

Module(s) shall only be changed with the co-operation of the maintenance desk operator. The signaller shall be informed of any likely effects.

Determine whether the fibre optic cable(s) to be tested are part of the primary or the secondary system. If the system on which tests are to be performed is active, check that the alternative system and its components are functioning correctly before commencing tests.

These tests require use of specialist test equipment that shall only be used by an ‘Instrument Engineer’ or a ‘Special User’ who has been suitably trained in their use.

7.1 MSCC System Layout - Fibre Optic Interconnection



Simplified Layout – Single Link

Transmission between peripheral locations is at 1310 nm over single mode fibre, with SC-AP end connectors.

Transmission within the peripheral location between CTOS and FOA, FOA - FOA is at 850 nm over multi mode fibre, with ST end connectors.

The entire transmission network duplicated with automatic changeover to check system availability.

Notes:

*1: SC-AP connectors

*2: 1310 nm transmission over single mode fibre

*3: Fibre in external telecomm cable

*4: Multi mode fibre with ST connectors

*5: 850 nm transmission

7.2 Values

Minimum bending radius **20 mm**

Transmission Level

Module	Input Sensitivity	Output Power
COML	-15 dBm	-31 dBm
COSL	-15 dBm	-31 dBm
CTOS	-15 dBm	-31 dBm
CTOM	-11.5 dBm	-24 dBm
COMX	-11.5 dBm	-24 dBm
FOA	-15 dBm	-31 dBm
PCDR	-11.5 dBm	-24 dBm

Maximum permissible loss

Component	Loss
Fibre optic patch cord	1 dB
Fibre optic cable section (Single mode, 1310 nm)	23 dB

For actual fibre optic cable section losses refer to loss budget records in local documentation.

Permissible attenuation for fibre optic components

Component	Loss
Connector (two connectors mated = one connection)	0.40 dB
Splice	0.05 dB
Fibre Loss (Single mode, 1550nm)	0.22 dB per km
Fibre Loss (Single mode, 1310nm)	0.22 dB per km

Calculated Attenuation for a Fibre Optic Cable Section

If the actual loss exceeds the budget records or the calculated section loss, investigation is required. Tables for calculation of expected section loss are given below.

Permissible attenuation for fibre optic cable section

Component	Quantity	Loss (dB)	Product
Connector		0.40 dB	
Splice		0.05 dB	
Fibre Loss		0.22 dB per km	
Total (Calculated loss for section)			dB

Typical Attenuation for Fibre Optic Components

Component	Loss
Connector (two connectors mated = one connection)	0.40 dB
Splice	0.05 dB
Fibre Loss (Single mode, 1550nm)	0.22 dB per km
Fibre Loss (Single mode, 1310nm)	0.22 dB per km

7.3 Connector types in use

	Lead connector	Card connector
COML/COSL	SC	SC
Telecoms interface	SC-APC	SC-APC
CTOS	ST	ST
FOA	ST	ST

8 SERVICE REPLACMENT COMPONENTS

8.1 Track Circuit Capacitor (TH)

The track circuit capacitor (TH) is fixed to a mounting plate that is secured to the rack with the plugboard’s lower fixing screw.

Description	Type
Track Circuit Capacitor (TH) 2.2µF	Capacitor (ASF) N9502700225

Description	NRS Part Number
Mounting Plate	NRS 0050/000694

8.2 Field Adaption Unit

The original units have been discontinued. Equivalent units providing the same functionality are available under the following part numbers:

Old Part Number	New Part Number
MSC/11/00/00	FF05-000-SG-DRG000001
MSC/11/00/01	FF05-000-SG-DRG000002
MSC/11/00/02	FF05-000-SG-DRG000003
MSC/11/00/03	FF05-000-SG-DRG000004

Old Part Number	New Part Number
MSC/11/00/04	FF05-000-SG-DRG000005
MSC/11/00/05	FF05-000-SG-DRG000006
MSC/11/00/06	FF05-000-SG-DRG000007
MSC/11/00/07	FF05-000-SG-DRG000008
MSC/11/00/08	FF05-000-SG-DRG000009

8.3 POT Field Device Controllers

The firmware installed on the original POTs that interface the BR867 Track Feed Units and SD321 Main Signals to the Ansaldo ACC interlocking has been updated. The new unit is available under the following part number:

Old Part Number	New Part Number
FM9088300400	FM90883000402

8.4 CDEV Board

The surge arrestor has been removed from the CDEV board and a new part number allocated. The new board is available under the following part number:

Old Part Number	New Part Number
FM9088300903	CDEV-06 B22B.0100150

8.5 CTRC

The CTRC has been modified in compliance with the SHWW redesign. The version has been incremented but the existing part number has been retained. Some of the earlier boards may have been modified and labelled accordingly. If an early type board is not labelled it shall not be used and should be returned to the store or to your SM(S) so that it can be returned to the manufacturer for modification.

Version	Part Number
See wiring diagram	B2GB.000021

End

1. Road Traffic Light Signals

1.1 General Description

Early type traffic lights were fitted with 36-watt filament lamps and can often be identified by the high visibility white border on the periphery of the lamp backboard.

The later filament type is fitted with 50-watt Quartz Halogen (QH) lamps and can be identified by the high visibility red and white border on the periphery of the lamp backboard.

A new LED unit is now approved. The three types shall not be mixed at the same crossing.

Many older installations have been converted to use the 50-watt QH lamps to comply with the improved performance for road traffic light signals specified by BS505. On early conversions the high visibility red and white border was clamped on to the existing backboard.

The modified assemblies were fitted with a GEC identification label on the underside of the lamp bowl unit. The red lamp unit should be labelled LL5101 and the amber lamp unit LL5102.

1.2 Lens Orientation

It is important that the plastic lens (Red or Amber) is installed correctly and that the beam is concentrated downwards.

The plastic lens comprises a large number of small lenses arranged in rows on the rear face of the lens. The lens shall be installed with the arch of the small lenses upper most. Some lenses might have the word “TOP” embossed on the inner or outer face near the edge of the lens to indicate the correct orientation. See Figure 1.

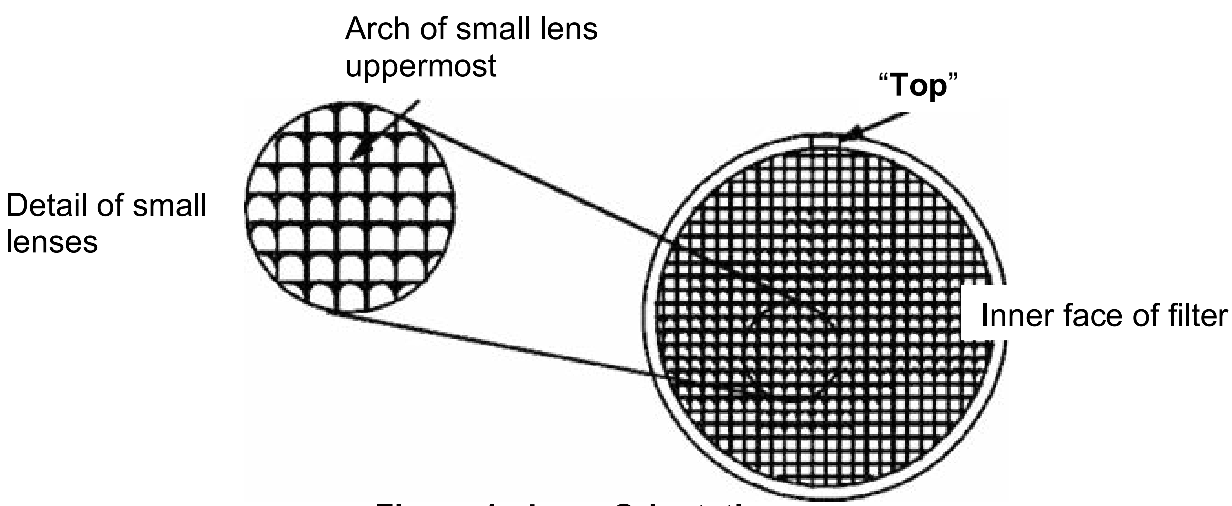


Figure 1 - Lens Orientation

The lens fitted to the QH type lamp assembly should have “TOP” moulded on a small raised block on the rim at the rear of the lens.

The latest type of traffic lights replacing the 50W QH lamps are LED based.

LED modules are NOT interchangeable with the current lamp assemblies and cannot be replaced individually, nor can they be mixed on the same crossing.

2. Booms

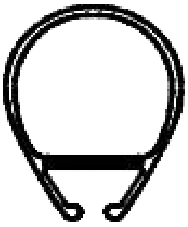
2.1 General Description

Booms may be constructed of wood, aluminium or glass reinforced plastic (GRP) e.g. Western Region type barrier.

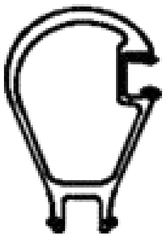
The method of construction can also vary. Timber booms may be laminated or jointed lengths of solid timber.

Other types, such as boom gates, are constructed of marine ply to form a box section approximately 300 mm x 200 mm. The addition of vertical timbers creates the “gate like” assembly.

Some barrier machines are similar in design but are fitted with booms of different cross section. When replacing a damaged boom, it is essential for the continued correct operation of the barrier equipment that the replacement boom is the correct length and that the boom cross section is correct for the machine. See Figure 3 also Barrier out of Balance (Tip) Force.



Used on G.W.E. Type Manually Controlled



Used on BR Spec. 843 machines manufactured by G.W.E. and Smiths Industries

Figure 2 - Cross section of typical metal booms

SPX style booms shall be measured from the centre bolt of the side arm, older GWE’s shall be from the end of the slot for the boom within the side arm, Penguins shall be from the centre pivot.

3. “Sangamo” or “Schlumberger” Time Switches

NOTE: *These time switches are no longer permitted and shall be replaced by the SELC electronic timer.*

3.1 Back-up Battery

The 110V supply cannot supply the peak pulse currents required by the time switch mechanism. These pulses are supplied from the internal back up battery which is also there to cover for power failures.

The backup battery is therefore essential to the correct operation of the time switch, such that a faulty battery can seriously affect the accuracy of the device.

As the purpose of the time switch is for controlling / muting the night time Yodalarm output, a slow time switch can eventually result in a muted Yodalarm during day time operation.

If a clock consistently loses time, arrangements shall be made to replace the time switch as soon as practicable.

Even if the time switch appears to be accurate the battery condition can be examined as follows:

- Remove the Cover
- Detach the timer dial by unscrewing the screw in the centre of the dial and easing it off. Do not turn the knurled Knob.

If the battery shows any sign of discharge or contamination, the complete unit should be considered as being defective and a replacement obtained.

The battery, which is incorporated in the printed circuit, cannot be replaced on site.

The battery should be examined when installing time switches as the battery condition can also deteriorate during storage.

NOTE: *The manufacturer recommends that the life expectancy of the backup battery with continuous use is approximately 10 years. However, prolonged storage in a discharged state may have an effect on the battery, limiting the life expectancy. It is recommended that the time switch is replaced at five-year intervals.*

3.2 Day Omit Device

The “Sangamo” or “Schlumberger” time switches may also incorporate a “Day Omit” option which is not required when they are used at level crossings. It is extremely important that this option is disabled. There are two methods by which this may be achieved.

The “Day Omit” option is controlled by seven arrows, one for each day. It is therefore extremely important that this option is disabled for each day of the week. Otherwise the volume of the “Yodalarm” will be muted during the daytime on those days not disabled.

Method 1

a) The position of the arrows on the “Day Omit” dial may be observed by carefully turning the “Day Omit” dial so that each arrow is just visible in turn at the edge of the main dial. The arrows on the face of the “Day Omit” dial shall be set to point towards the centre of the dial. See Figure 3. Take care not to rotate the timer dial.

b) To adjust the direction of an arrow, use a small flat bladed screw driver (blade approx. 3mm wide) and turn the arrow in an anti-clockwise direction until it points towards the centre of the “Day Omit” dial.

c) Check that the time setting is correct.

Method 2

Remove the central screw holding the timer dial and carefully lift it off. See Figure 3.

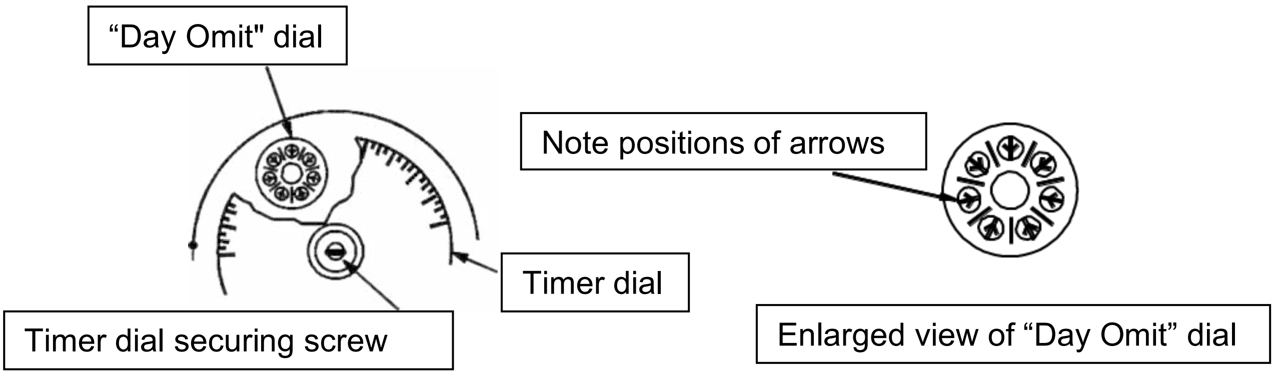


Figure 3 – Time Omit Device

Caution: Do not turn the knurled knob because the “ON” and “OFF” timing tappets will be loosened, and their relative time settings may be lost.

The arrows on the face of the “Day Omit” dial shall be set to point towards the centre of the dial.

To adjust the direction of an arrow, use a small flat bladed screw driver (blade approx. 3mm wide) and turn the arrow in an anti-clockwise direction until it points towards the centre of the “Day Omit” dial.

When all the arrows of the “Day Omit” device are set correctly, carefully replace the timer dial and secure with the centre screw.

Check that the time setting is correct.

3.3 Volume Control Adjustment

The times when the volume of the audible warning is to be reduced will be stipulated in the level crossing order or on the crossing layout drawing where an order does not exist. The timer “ON” and “OFF” tappets shall be set to correspond with these times.

The standard time clocks are supplied with pairs of “ON” and “OFF” tappets. The second tappet acting as a back-up for each type. The “ON” tappets switch the audible warning to the higher volume (Day setting) and the “OFF” tappets to the reduced volume (Night setting). i.e. “ON” days and “OFF” nights.

The first tappet of each type (“ON” or “OFF”) should be set to the time specified in the Order or layout drawing. The second (back-up) tappet of the pair should be set to follow approximately one hour later.

The latest type of time switch made by a firm called SELC. It is electronically based, and it carries out the change to and from British Summer Time (BST) automatically. In early 2008 each area was supplied with a sufficient quantity of SELC timers to replace the previous mechanical type. These should be replaced at the NEXT maintenance visit or failing that at the earliest opportunity.

4. British Railways Board Automatic Half Barrier Crossing - Machines

4.1 General Description

The British Railways Board (BRB) Mk I and Mk II Automatic Half Barrier Crossing (AHBC) machines are often referred to as the “Penguin” type because of the bulbous shape of the concrete column.

The column tapers towards the top and may carry the road traffic light signals. At many crossings the road traffic light signals have been removed from the column and the typical post mounted road traffic light signal assembly has been installed adjacent to the machine.

The barrier operating equipment is housed in a steel frame mounted to the rear of the column. Robust moulded ABS plastic covers protect the equipment. The ‘Y’ barrier machine, contained the telephone and local controls.

Two doors were provided in the side of the top cover, one for public access to the telephone and the other for operator access to the Local Control Unit.

The operator's door is fitted with a locking device activated by a magnet bonded to the inner face of the machine cover adjacent to the door lock.

When the door is closed and locked, the magnet lifts a gravity-operated pawl at the rear of the lock permitting the key to be withdrawn.

At some installations the telephone has been removed. A cover without a telephone access door has been fitted to the machine.

This modified cover is necessary to prevent unauthorised access to the local control buttons via the adjacent unlocked telephone door.

The telephone is usually relocated in a weatherproof housing mounted on a post adjacent to the barrier machine. Similar arrangements may also apply to the local control unit.

The timber boom is mounted on boom carriers on either side of the machine. The boom lengths range from 3.98 m (13ft 1in) to 6.02 m (19ft 9ins) pivot to tip.

Boom lengths of 3.35 m (11ft 0ins) to 3.96 m (13ft 0ins) are available for special installations.

Two boom lamps are usually fitted, one of which is mounted approximately 150 mm (6 ins) from the tip of the boom.

The boom carriers on either side of the machine are fitted with moulded ABS plastic covers. These covers, often referred to as the anti-guillotine shields, shall be fitted securely to provide protection from the equipment as it operates. Arrangements shall be made to replace the shields if they are damaged or missing.

On early models, the main shaft on which the boom mechanism rotates, was carried on plain shell bearings. This main shaft / shell bearing assembly required frequent re- alignment following bearing renewal or if the boom was damaged.

During the 1970s the main shaft / bearing assembly of many machines were converted to a self-aligning bearing arrangement utilising special washers. An oil hole was also provided in the top of the bearing housing.

Many machines were subsequently fitted with PTFE coated bearings to produce a self-lubricating bearing, consequently an oil hole was not provided in the bearing housing.

PTFE coated bearings shall not be oiled as the oil can cause the coating to deteriorate.

4.2 Top Ram Pin Clamp

The hydraulic ram, which operates the barrier, is pivoted from a ram bracket fitted to the bottom of the steel frame attached to the rear of the concrete column.

The bottom pivot may be either a ram pin or bolt and nut assembly. The top of the ram is connected to the boom driving lug sub-assembly by a ram pin.

The ram pins are secured with split pins except where the modified top ram pin is fitted.

The ram journal rotates around the top ram pin as the ram extends and retracts to raise and lower the barrier.

If the pin is not lubricated it is prone to seizure and the barrier might fail in the raised position.

This is a potential Wrong Side Failure condition. However, oiling shall be done carefully to avoid surplus oil contaminating the “Metalastik” bush fitted to the ram journal.

A clamp has been developed to prevent the top ram pin turning in the driving lug sub- assembly.

The ram pin has been modified to incorporate a central hole and a grease nipple, which is fitted to one end of the pin. See Figure 4.

This arrangement makes the lubrication easier to apply and is delivered direct to the ram journal.

The clamp and modified top ram pin assembly can be fitted on site.

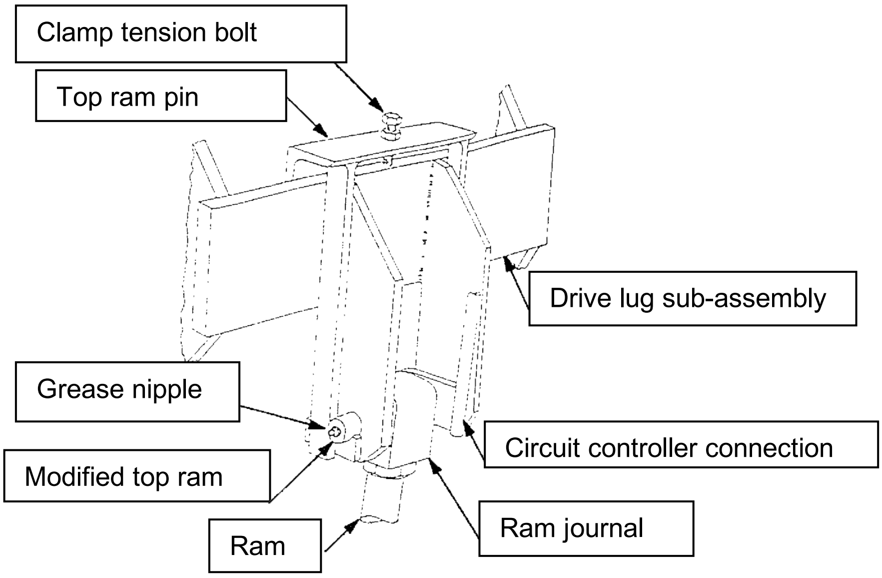

Figure 4 – Top Ram Pin Clamp Assembly

4.3 Local Control

The button switching mechanism is interlocked to check that only one button can be in the depressed position. When a button is depressed it is mechanically latched and is only released when another button is fully depressed and latched.

To check that the crossing is returned to automatic operation, the “Auto” button shall be depressed and the interlocking lever / cam assembly repositioned against the push button fascia.

The cam engages the aperture of the depressed “Auto” button verifying that the other buttons cannot be depressed. Unless this procedure is followed the access, door cannot be shut and locked.

The lever / cam assembly is an interlock and is not intended to force the “Auto” button into the latched position. The button shall remain latched until released by depression of another button.

Due to normal wear, free play might be present in the lever / cam assembly.

Therefore, it is very important that the “Auto” button remains latched irrespective of the position of the interlocking lever.

If the latching mechanism does not operate correctly, arrangements shall be made to replace the unit as soon as possible.

4.4 Barrier Out of Balance (Tip) Force

With the weights fitted and correctly adjusted, check the barrier is able to lower within the specified time. Incorrect setting can affect the lowering time.

The barrier might be slow to lower or prevented from lowering during windy conditions.

It is essential for the continued correct operation of the barrier machine that the correct boom is fitted, especially when a boom is replaced. If a boom of a different weight or of an incorrect length is fitted, the existing boom weights are likely to be incompatible and the out of balance force incorrect.

An incident occurred during strong windy conditions in which an incorrectly weighted boom was still lowering as the train passed over the crossing.

The boom eventually reached the lowered position, just within the time margin, allowing the crossing to normalise before the crossing indication time out period expired.

Consequently, the crossing operation was “normal” and the Signalman was unaware of the problem. A serious accident could have occurred.

Always check the replacement boom is a "like for like" replacement and that the out of balance (tip) force is correct even though the boom might appear to be identical.

NOTE: *Details of the out of balance tip force weights can be found in NR/SMS/PartZ/Z04 (Level Crossing – Reference Values).*

4.5 Hydraulic Unit (Removal)

a) Close the stop valve and manually raise the barrier to the fully raised position using the hand pump. See Figure 5.

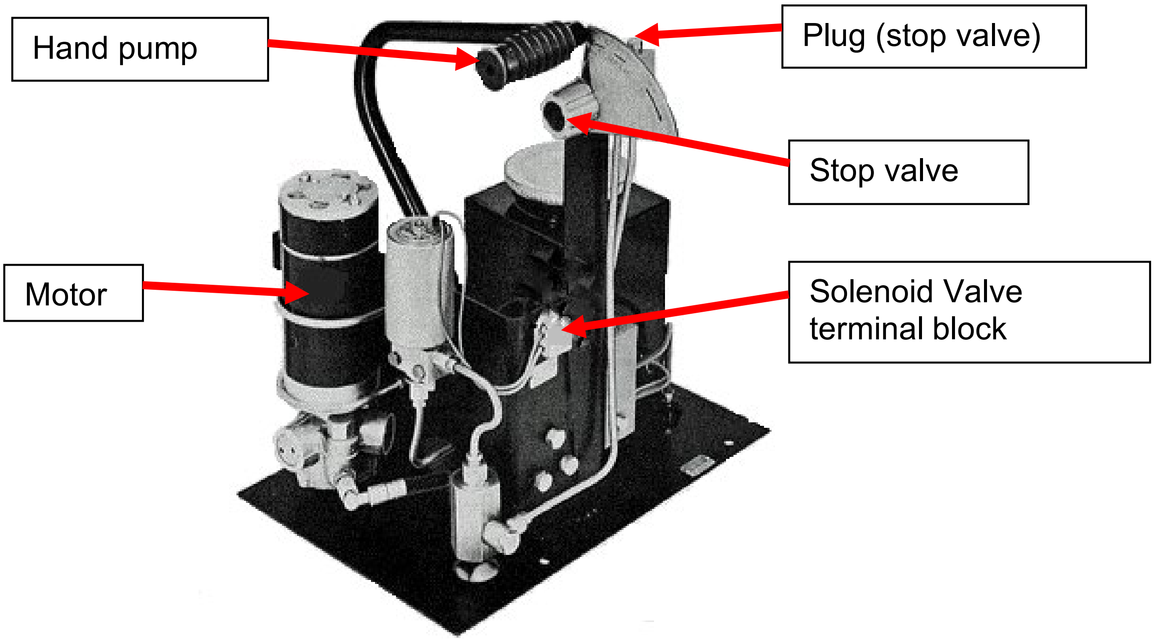

Figure 5 – Hydraulic Unit

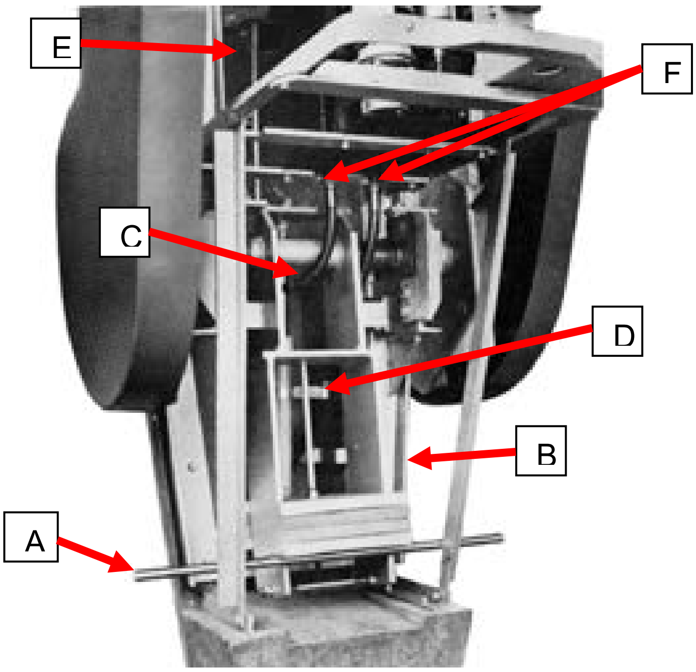

Figure 6 – Hydraulic Unit (Replacement)

b) Place a strong bar (A) between the machine frame and the counter balance weight carrier arm (B). See Figure 6.

c) Open the stop valve (1) to release the hydraulic pressure.

d) Disconnect the wires from the motor (3).

e) Disconnect the wires from the solenoid valve terminal block (4).

f) Carefully remove the plug (5) from the top of the stop valve body and connect the special drain pipe.

g) Close the stop valve (1). With a clean container held beneath the drain pipe, use the manual hand pump (2) to drain the reservoir (E).

h) Loosen the hose connections (F) at the bottom of the reservoir.

i) Remove a blanking plug from the connection at the bottom of the new unit.

j) Check the new unit is protected from contamination.

k) Disconnect one hose (C) and quickly fit the blanking plug to the connection (F) to prevent residual oil running out of the reservoir.

l) Temporarily tie the hose in an upright position to prevent loss of oil.

m) Repeat disconnection procedure for the other hose.

n) Remove the bolts securing the hydraulic unit to the machine frame.

o) Carefully remove the hydraulic unit from the machine frame.

4.6 Hydraulic Unit (Replacement)

a) Manoeuvre the hydraulic unit into the machine frame and bolt in position.

b) Reconnect the flexible hoses (C) to reservoir connections (F).

NOTE: *The hoses shall also be renewed at the time the pack is replaced as any contamination within the existing hoses can migrate back into the reservoir of the pack thus causing early ‘hunting’ problems of the new pack as the contamination takes effect.*

c) Check the bracket (D) securing the flexible hose to the ram body is secure.

d) Reconnect the wires to the solenoid valve terminal block (4).

e) Reconnect the wires to the motor terminals (3).

f) Fill the reservoir with clean approved hydraulic oil. Use the dipstick attached to the filler cap to determine the level. The reservoir capacity is approximately 2.3 litres (1/2 gallon).

g) Close the stop valve (1) and operate the hand pump.

h) With the boom manually supported carefully remove the locking bar (A).

i) Open the stop valve (1) and lower the boom.

j) Use the hand pump (2) to fully raise and lower the boom 3 times to bleed air from the system.

k) Restore the machine to power operation and raise and lower the boom 3 or 4 times and observe that the machine operates correctly.

l) Check the hydraulic system for leaks and rectify as necessary.

m) Check the level of the hydraulic oil and top up as necessary.

n) Replace the filler cap.

o) Check the operating time is correct.

RAISE TIME	4 to 5 seconds
LOWER TIME	6 to 8 seconds

p) Restore machine to automatic operation. See Restoring to Service.

5. G.W.E. Electro / Mechanical and Electro / Hydraulic Barrier Machine

5.1 Limit Switch

The 24-volt battery feed is housed in the pedestal of the Electro/Mechanical barrier machine

The limit switches fitted to the G.W.E. Electro/Mechanical and Electro/Hydraulic machines are manufactured by Crabtree.

The original switches were manufactured with the hole centres spaced at 30 mm x 80 mm and are identified by the Crabtree part number 24395. These dimensions were subsequently changed to 30 mm x 60 mm. The later type can be identified by the Crabtree part number 15045/2.

NOTE: *The original Crabtree switches are now obsolete. New Honeywell types are available but require the mounting plate changing at the same time.*

The Crabtree switches are not interchangeable and the whole mounting plate should be changed. When switches are changed it is essential that the mounting plate and switches are secure and the contact gap is correct.

The internal switch unit is secured within the metal housing by two screws. The housing is tapped to accept a conduit connection; however, when used in the barrier machine a plastic insert is fitted forming an open entry gland for the cable.

Drops of moisture can enter the switch unit through the open cable gland. The resulting contamination and corrosion could cause the switch to malfunction and could result in a Wrong Side Failure. It is therefore essential that the anti-condensation heaters and the thermostat operate correctly. The thermostat should be set to approximately 16°C (60°F).

A rubber grommet or similar cable gland sheath should prevent the ingress of moisture. Mastic sealant is not recommended as it might enter the switch and affect the operation of the contacts and could result in a Wrong Side Failure.

6. G.W.E. Electro/Mechanical Barrier Machine, Electro-Magnetic Clutch Mechanism Type

6.1 Barrier Damping Adjustment

The damper controls the lowering of the barrier and prevents the barrier end stop striking the road surface with excessive force, the result of which could damage the barrier and associated equipment. To check that the feature is operating correctly, proceed as follows:

a) Isolate the machine from power.

b) Observe the barrier as it descends.

The barrier should lower gently to the horizontal position and come to rest without bouncing.

If the damping is insufficient, turn the adjusting valve screw, if fitted, very slightly in a clockwise direction.

NOTE: *The damper adjusting screw is very sensitive and requires minimal adjustment to alter the damping effect. When the correct damping is obtained secure the screw with the locknut.*

If correct damping cannot be obtained by adjusting the screw, the barrier shall be re- balanced using the counter-weights. Moving the counter-weights can be used to increase their effective weight when the barrier is horizontal.

7. Lifting Barrier Machine to BR Spec 843

7.1 Main Shaft Weather Seals

When refurbishing the barrier machine, the seals and the exposed portions of the main shaft shall not be painted. (Else the seals can stick to the main shaft and are damaged when the barrier is operated. This can allow water to penetrate, which on freezing could prevent the barrier operating.

Seals that have been deformed, cut, or torn shall be replaced.

7.2 Main Shaft End Cap

Machines supplied with booms less than 7100 mm (pivot to tip) are not fitted with a support arm. An end cap should be fitted to the machine pedestal to cover the exposed end of the main shaft.

A mastic compound is used to provide a weatherproof seal between the end cap flange and the pedestal. The end cap shall be kept secure and the mastic seal in good condition to prevent the ingress of dirt and water which could freeze during the winter months.

Frozen grease and water caused both barriers at an AHB crossing to remain raised during the passage of a train. Grease expelled from the bearing during greasing could fill the end cap and extreme winter temperatures might cause it to freeze with similar results.

Packing the end cap with grease to prevent the ingress of water is not recommended for the same reason. The use of a frost resistance grease might be necessary during the winter months.

7.3 Boom Re-Fitting Procedure

a) Note the number and size of the weights on each side arm.

b) Remove the weights from the side arms.

c) Lift the side arm to the horizontal position and support.

d) Replace, if necessary, the displacement detection micro switch. See boom displacement detection micro switch re-fitting procedure.

e) Locate the boom adapter (pre-assembled to the boom) on to the two taper bushes fitted to the side arm. Check that the boom adapter is correctly seated in the side arm channel. See Figure 7.

f) Secure with two M12 x 70 bolts, each bolt to be complete with special thick washer (16 mm internal diameter) under the head of the bolt, M12 plain washer and an ordinary M12 hexagonal nut. See Figure 7.

g) Support the boom assembly at the tip.

h) Check that the boom and boom adapter fastenings are tight.

i) Fit and secure, if provided, the skirt linkage to the pedestal.

j) Fit and secure, if provided, support frame. See Support Frame Re-Fitting.

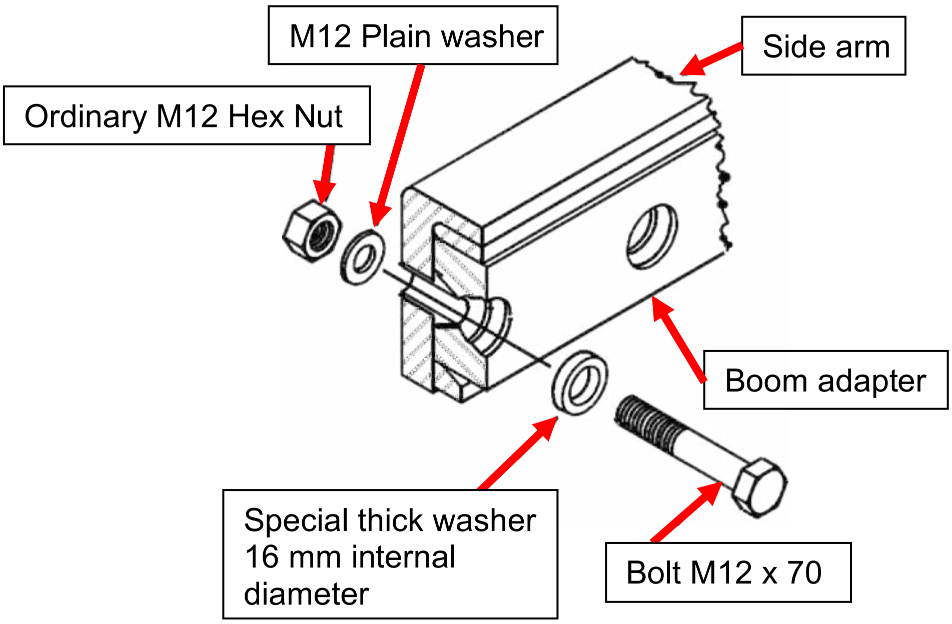

Figure 7 - Boom adapter to side arm - initial assembly

Assemble the Locating Pins with the Special Thick Washer (16 mm internal diameter), “E” Clip, and M6 Slotted Pan Head Screw. See Figure 8.

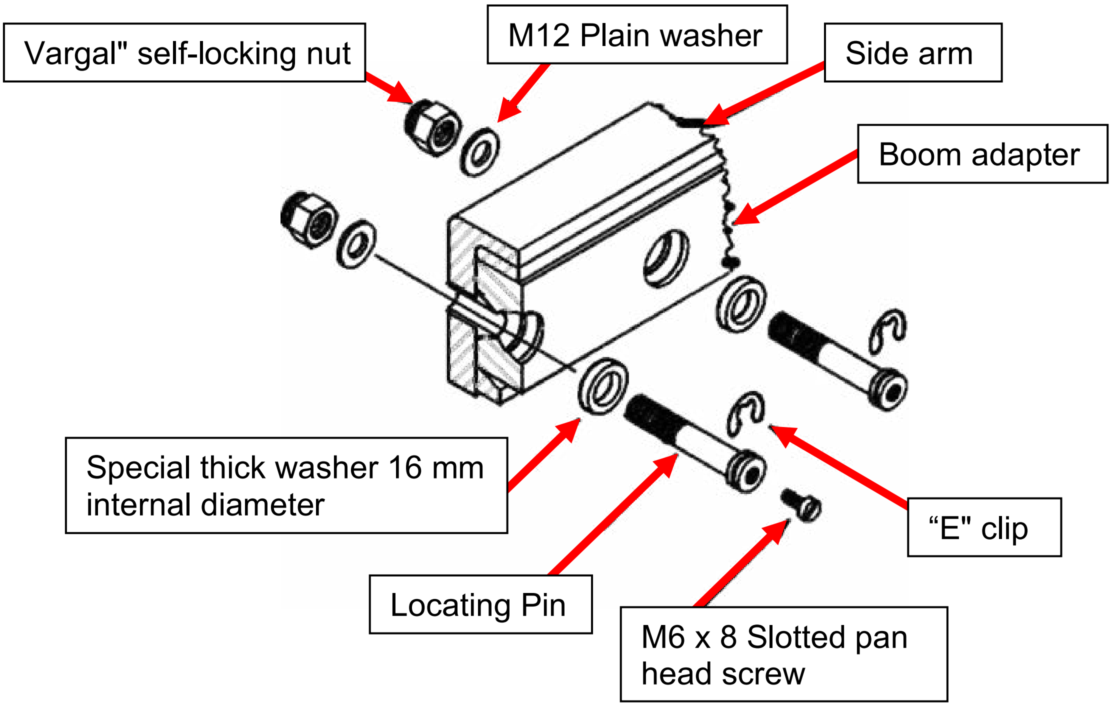

Figure 8 - Boom adapter to side arm fixing

k) Apply adhesive type grease to the locating pin assembly.

l) Remove one temporary M12 x 70 bolt assembly. Replace with a locating pin assembly complete with the special thick washer, M12 plain washer and "Vargal" self-locking nut.

NOTE: *The "Vargal" self-locking nut is designed to be re-used.*

m) Hold the locating pin assembly by inserting a screw driver into the slot of the M6 pan head screw. Tighten the "Vargal" self-locking nut to 16 Nm (12lbs. ft).

n) Remove the M6 pan head screw.

o) Repeat the procedure for the other temporary bolt assembly.

p) Pack the locating pin "E" clip cavity with adhesive type grease.

q) Fit the flexible conduit, which carries the boom light and displacement detection wires, over the fulcrum and then into the pedestal. Secure by means of the cable clips.

r) Route the boom light and displacement detection wires within the pedestal and fix into position. Check that the wires are supported clear of all moving parts and cannot become trapped when the door is closed or when the ram unit operates.

s) Remove the support from the side arm, fit, and secure the weights.

t) Fit, if provided, the strainer wire and adjust as necessary. See '7.6 Strainer Wire Re-Fitting'.

u) Terminate the boom light and displacement detection wires and check that the circuits operate correctly.

v) Measure the tip force and adjust the weights as necessary.

w) Operate the machine manually.

x) Power operate the barrier five times and observe that the operation is satisfactory.

y) Re-adjust the strainer wire, if necessary. See '7.7 Strainer Wire Tension'.

7.4 Assembly Bolts and Spare Locating Pins

It is good practice to keep the M20 x 70 bolts, nuts, washers, spare locating pins complete with "E" clips, M6 pan head screws, "Vargal" nuts and washers in a bag in the relay room or REB. The components are then readily available in the event of boom displacement or false indication.

Where the components have to be stored in the machine pedestal, check that they cannot interfere with the operation of the machine. Anti-rust protection may be necessary in some locations. Rusted or distorted "E" clips shall be replaced otherwise they might fail prematurely in service or during installation.

7.5 Support Frame Re-Fitting Procedure

NOTE: *The support frame shall not be fitted until the boom has been fitted.*

a) Slide the clamp plates into their approximate positions in the boom slot.

b) Fit and secure the support frame adapter to the support frame.

c) Position the Support Frame Adapter and using a 12 mm A/F Hex. Wrench Key screw the two M12 Taper Ended Screws so they protrude into the Side Arm. See Figure 9.

d) Commencing at the Pedestal End of the Support Frame, secure each Cross Member to a Clamp Plate with two M12 x 25 mm bolts and M12 washers. See Figure 10.

e) Check that the Cross-Member fastenings are tight.

f) Adjust the two M12 Taper Ended Screws so their taper ends protrude into the Side Arm by approximately 10 mm when measured from its outside face.

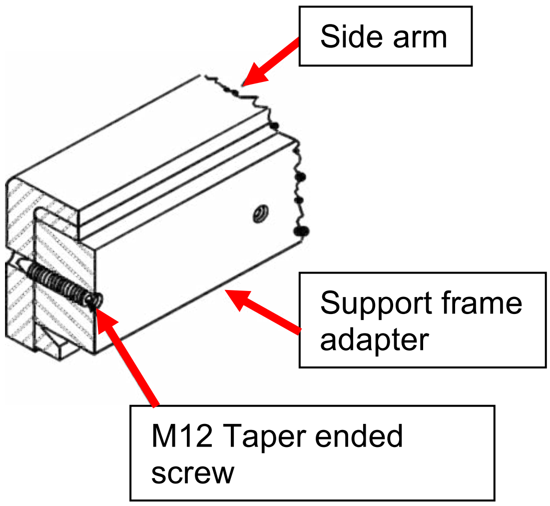

Figure 9 - Support frame adapter and side arm assembly

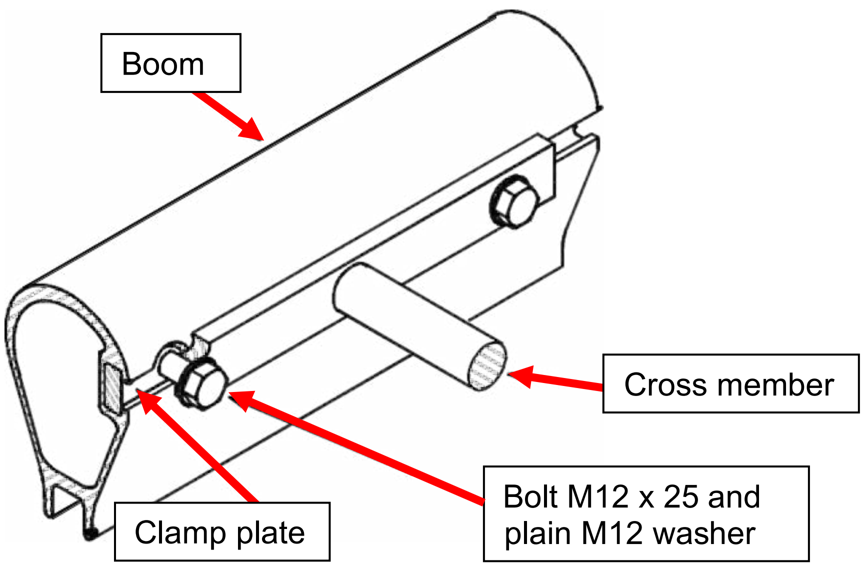

Figure 10 - Cross member to boom assembly

7.6 Strainer Wire Re-Fitting Procedure

a) Fit and secure the Strainer Wire Support and Rear Anchorage assemblies onto the Side Arm.

b) Check that the Boom Tip Eye Bolt assembly is secure.

c) Fit and secure the Strainer Wire.

d) Adjust the tension of the Strainer Wire so that the boom is straight throughout its length. See ‘7.7 Strainer Wire Tension’.

NOTE: *Only approved strainer wire shall be used.*

7.7 Strainer Wire Tension

If after carrying out the SMS process or replacing a strainer wire it requires to be tensioned the following process should be carried out.

With the barrier in the lowered position the strainer wire should maintain the boom in a straight alignment (i.e. minimum sag).

If a boom support is provided it should be removed temporarily before assessing the alignment of the boom or adjusting the tension of the strainer wire.

This is to check that enough tension is applied to the strainer wire to maintain the boom in straight alignment.

When the tension is correct, tighten the Rear Anchorage adjusting nuts.

Apply adhesive type grease to the exposed adjuster threads to protect the threads and make adjustment easier when required.

Refit the boom support, if provided.

7.8 Boom Displacement Detection Micro Switch Replacement Procedure

The micro switch assembly comprises a mounting bracket to which is fitted the micro switch and a short length of wiring harness encased in a flexible conduit. The micro switch assembly is fitted to the underside of the boom adapter. See Figures 11 and 12.

a) Remove the M6 x 15 screw.

b) Remove the M4 Dog point socket head screw.

c) Loosen the M4 socket head screw securing the conduit clamp to the inner face of the side arm.

d) Disconnect the 4-pin connector. (Adjacent to the conduit clamp).

e) Remove the short length of skirt channel (complete with skirt rods, where fitted)

f) Disconnect the 2-pin connector. (Adjacent to the micro switch).

g) Loosen the M4 socket head screw securing the conduit clamp to the boom adapter.

h) Remove the two M4 pan head screws securing the micro switch mounting bracket to the boom adapter.

i) Remove the old micro switch assembly.

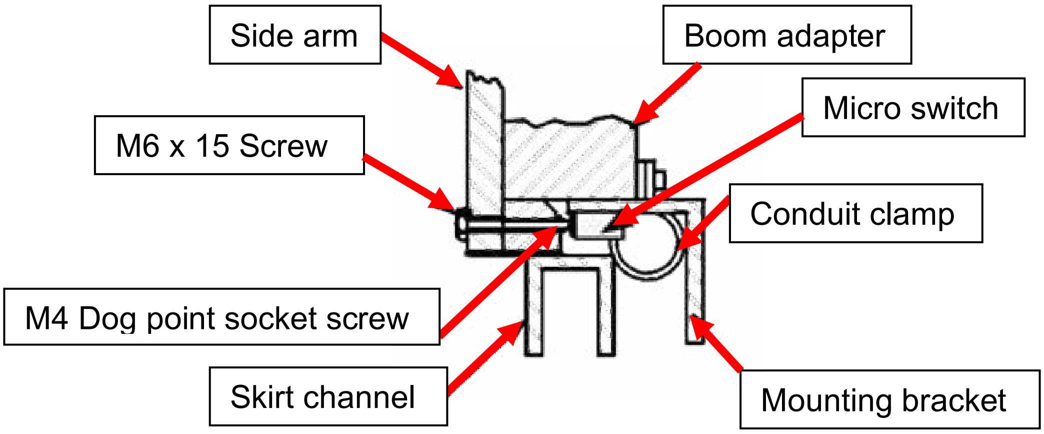

Figure 11 - Section through boom assembly looking towards the machine (cables and wires not shown)

j) Fit the new micro switch assembly and secure to the boom adapter.

k) Locate the flexible conduit in the conduit clamp.

l) Tighten the conduit clamp securing screw.

m) Reconnect the 2-pin connector.

n) Refit the short length of skirt channel (complete with skirt rods, where fitted).

o) Reconnect the 4-pin connector.

p) Tighten the conduit clamp securing screw.

q) Set the boom detection by carefully adjusting the M4 Dog point socket screw until the micro switch contacts just 'make'.

NOTE: *This should be undertaken using a multi-meter as over-tightening of the Dog Point socket screw can cause severe damage to the micro-switch assembly*

r) Turn the screw a further ½ turn (maximum).

s) Refit the M6 x 15 screw to protect the micro switch adjusting screw.

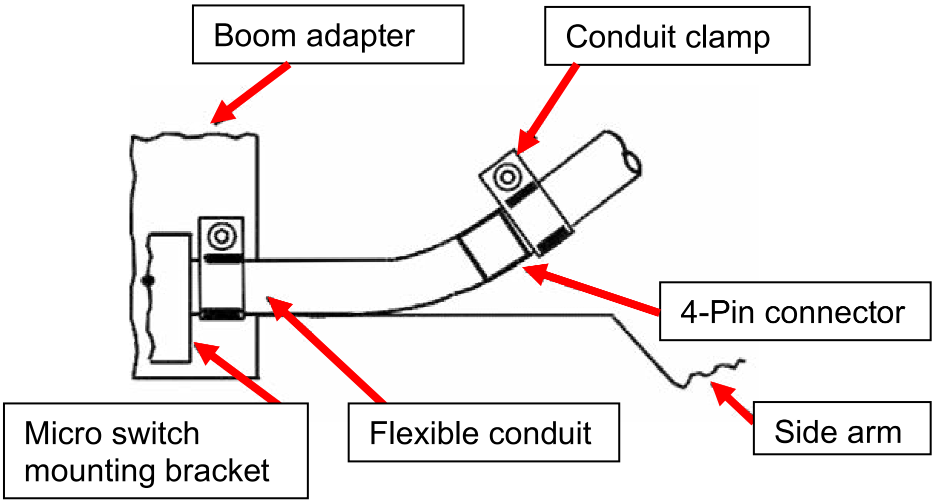

Figure 12 - Micro switch mounting

It is important that the 4-pin connector is located on the correct side of the side arm conduit clamp. Otherwise the connector might not pull apart when the boom is dislodged and the boom displacement detection could fail to operate. To prevent the cable being strained the clamps shall be secure and the conduit held firmly without damage.

7.9 False Indication of Boom Displacement

If false indications of boom displacement are reported, check the setting of the M4 Dog point socket screw that operates the micro switch.

This screw is located beneath the M6 x 15 mm screw fitted at the lower edge of the side arm. See Figure 11.

a) The M4 Dog point socket screw should be set so that the micro switch contacts just 'make'.

NOTE: *This should be undertaken using a multi-meter as over-tightening of the Dog Point socket screw can cause severe damage to the micro-switch assembly*

b) The screw should be turned a further 1/2 turn (maximum).

c) Refit the M6 x 15 screw to protect the micro switch adjusting screw.

If the setting was found to be correct, check that the boom adapter is securely fitted to the side arm. Any movement of the boom adapter might cause the micro switch to operate.

If movement of the boom adapter is suspected, do not try to secure it by tightening the nuts on the locating pins otherwise the “E” clips might be distorted or displaced.

Use the M12 x 70 bolt, washer, and nut assembly to tighten the boom adapter onto the side arm. See ‘7.3 Boom Re-fitting Procedure’.

7.10 Barrier Out of Balance (Tip) Force

With the weights fitted and correctly adjusted, check the barrier is able to lower within the specified time. Incorrect setting can affect the lowering time.

Incorrect setting could affect the lowering time or might prevent the barrier from lowering during windy conditions.

It is essential for the continued correct operation of the barrier machine that the correct type of boom is fitted, especially when a boom is replaced.

If a boom of a different weight or of an incorrect length is fitted, the existing boom weights are likely to be incompatible and the Out of Balance Force incorrect.

An incident occurred during strong windy conditions in which an incorrectly weighted boom was still lowering as the train passed over the crossing. The boom eventually reached the lowered position, just within the time margin, allowing the crossing to normalise before the crossing indication time out period expired.

Consequently, the crossing operation was “normal” and the Signaller was unaware of the problem. A serious accident could have occurred.

Always check the replacement boom is a “like for like” replacement and that the Out of Balance (Tip) Force is correct even though the boom might appear to be identical.

Correct setting of the Out of Balance (Tip) Force is especially important at Automatic Half Barrier Crossing (AHBC), Automatic Full Barrier Crossings Locally Monitored (AFBCL), Automatic Barrier Crossing Locally Monitored (ABCL) and Automatic Open Crossing Locally Monitored plus Barriers (AOCL+B) installations.

NOTE: *Details of the out of balance tip force weights can be found in NR/SMS/PartZ/Z04 (Level Crossing – Reference Values).*

7.11 Hydraulic Unit (Removal)

The power pack can be changed with the barrier either raised or lowered. If, due to local traffic conditions, the pack has to be changed with the barrier in the raised position check that it is safely secured.

NOTE: *Failure to do so results in the barrier crashing down.*

a) Lower the boom.

b) Isolate the machine from the power supply and disconnect the plug coupler on the top of the unit.

c) Remove the bolts from bottom bracket (3). See Figure 13

d) Check that the unit is supported in an upright position and remove the bolts from the top bracket (2).

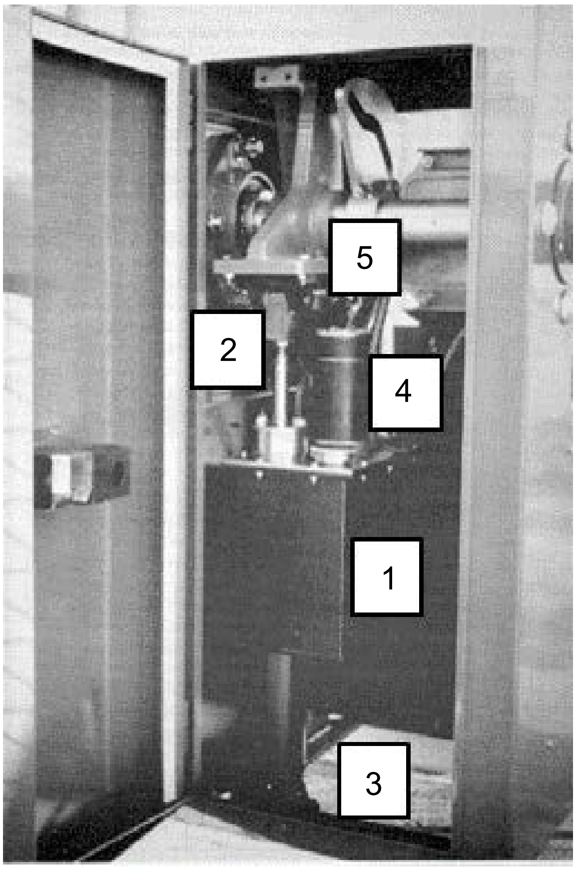
e) Note which holes in the operating arm were used as there are two fixing positions ‘Short Stroke’ and ‘Long Stroke’. The holes not used should have been fitted with nuts and bolts painted red during manufacture. (Arrange replacement if they are missing).

f) The “Long Stroke” position (bolt holes furthest from the pivot shaft) is used if the boom length is in excess of 7100 mm (pivot to tip).

g) Lift the hydraulic unit (3) remove from the barrier machine pedestal.

h) The hydraulic oil can be drained from the unit via the reservoir filler.

i) Replace the cap securely to prevent the ingress of dirt or water.



1 Hydraulic unit and reservoir.

2 Top pivot bracket (see note 2).

3 Bottom pivot bracket (see note 2).

4 Motor.

5 Ram-rod adjustment (see note 1).

Figure 13 – Barrier unit Internal components (front)

NOTE: *The PTFE lined pivot bearings shall not be lubricated.*

NOTE 2: *The length of the ram-rod is set during manufacture and shall not be altered as this affects the timings and damage the machine.*

7.12 Hydraulic Unit (Replacement)

NOTE: *It should be noted that there are two different types of power packs which can be fitted within a BR843 cabinet.*

The Grey units are fitted within AHB and MCB installations and fail in the lowered position if the solenoid feed is disconnected.

Blue coloured units are fitted within ABCL installations and require the solenoids to be energised for the barrier to lower. (i.e. they can fail in the raised position). It should be noted that some drive up drive down GWE units have been replaced with blue packs.

The correct type of power pack should be selected.

a) Remove the new unit from its transit box. Use box to return old unit.

b) Clean the pivot bracket fixing bolts, if necessary.

c) Hold the unit upright and carefully position the bottom pivot bracket (3) onto the mounting in the base of the pedestal and bolt in position.

d) With the unit supported in an upright position fill the reservoir (1) with clean approved hydraulic oil until it is visible in the strainer. The reservoir capacity is 10 litres (2.2 gallons).

e) Check the machine is isolated from the power supply and reconnect the plug coupler.

NOTE: *Current packs are self-bleeding. If the pack is not self-bleeding, the ram shall not be connected to the operating arm until the hydraulic system has been bled as follows:*

f) Keep the unit in the upright position and use the manual pump handle to fully extend the ram.

g) Continue to pump for another 5 full strokes of the manual pump handle.

h) Stow the manual pump handle and restore the power to the motor and solenoid valve.

i) Operate the motor for approximately ten seconds and then isolate the machine from the power supply.

j) Check that the ram top pivot bracket (2) is located in the same position on the operating arm as the original unit and bolt in position.

k) Top and bottom pivot securing bolts shall be fitted with TAB washers.

NOTE: *The dimension between the joint faces of the top and bottom pivot brackets is set at the factory to check that the boom should be horizontal when fully lowered.*

This dimension shall not be altered. Unauthorised adjustment of the ram-rod length might result in incorrect operating times and could damage the ram and associated equipment.

l) Using the hand pump, check that the machine operates correctly. Raise and lower the boom 2 or 3 times. Approximately 20 full strokes of the handle should be necessary to fully raise the boom.

m) Restore the machine to power and raise and lower the boom 3 or 4 times and observe that the machine operates correctly.

n) The barrier should rise smoothly without hesitation and should not oscillate excessively during the last few degrees of movement.

o) Check the operating time is correct.

Boom Length	Up to 7.3 m (24 ft)	Over 7.3 m (24 ft)
Raise Time	4 to 6 seconds	6 to 8 seconds
Lower Time	6 to 8 seconds	8 to 10 seconds

p) Power the boom to the fully raised position. Observe that the boom rises smoothly and remains in the fully raised position without any signs of lowering.

q) When the boom is released, it should lower smoothly and be damped during the last 10° of fall.

r) Set the Auto / Manual valve to the correct mode of operation and secure with the pin and wire seal. See Lock Down Feature Also Restoring to Service.

s) Check the level of the hydraulic oil, top up as necessary. The oil should be just visible in the filler strainer.

t) Replace the filler cap securely.

7.13 Operators Door Micro Switch

When the operators’ door is closed and locked it is electrically proven by a micro switch operated by the movement of the lock tongue.

Problems have occurred when the door has been locked but not proven. To check correct operation of the lock and micro switch proceed as follows:

a) Check that the door is free of obstruction and fully closed.

b) Insert the “Allen” key and turn it clockwise ¼ of a turn to engage the door latch behind the door rebate. Remove the “Allen” key.

c) Turn the Yale key fully in the clockwise direction to verify the maximum extension of the lock tongue and the satisfactory operation of the micro switch via the spring-loaded plunger.

d) Turn the key anti-clockwise to the vertical position and withdraw it.

NOTE: *Unless the Yale key is turned to its fullest extent the door could be locked but not proven. If the door closed proving cannot be obtained on one door the plunger should be lubricated to make sure it moves freely.*

If the proving can still not be obtained then try another key. If both of these options do not work further fault finding should be undertaken. When the door is fully open the key should be removed to prevent it being damaged by the barrier back weight when lowering the barriers.

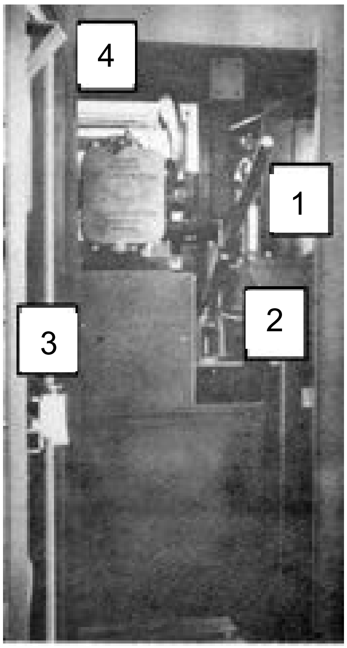
NOTE: *Do not force the key.*

7.14 Manual Pump Handle (Faulty Stowage)

The single acting telescopic manual pump handle is located in a casting bolted to the top of the reservoir.

When the handle is extended for manual operation it lowers into the pumping position. See Figure 14.

With the handle in this position it causes the hand lever stop (HLS) valve to close. Further downward movement operates the pump causing the barrier to rise.



1 Pump handle.

2 Pump handle casting bolted to top of reservoir.

3 Operators door.

4 Operators door pump handle check bracket.

Figure 14 - Barrier unit Internal components (rear)

The extended length of the handle is controlled by a spiral guide pin that protrudes through the slots in the lower shaft. When the handle is lifted, the spiral guide pin engages in guide slots in the pump handle casting.

The handle can then slide down into the stowed position causing the HLS valve to open and the barrier to lower. Unless the handle is in the stowed position the operators' door cannot be closed.

A potential wrong side failure condition was found during a routine test of an AHB crossing. The condition was created by the combination of a step at the bottom of the guide slot in the pump handle casting and a bent spiral guide pin. See Figures 15 and 16.

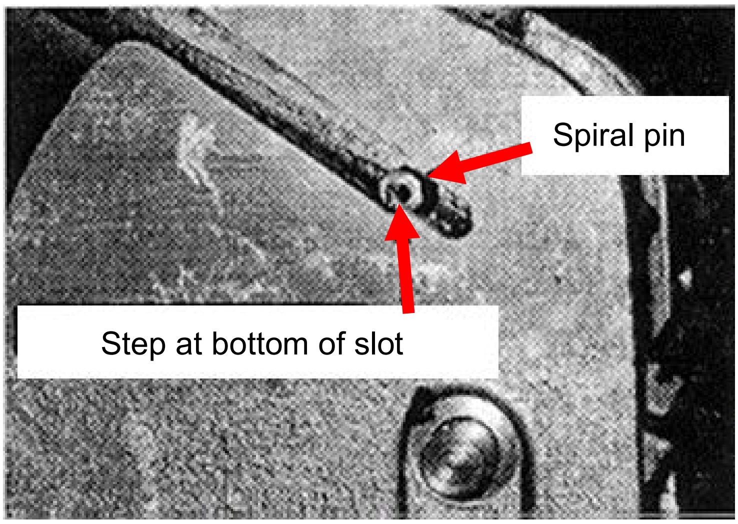


Figure 15 – Wrong side failure example

The step prevented the handle sliding fully home, whilst the bent spiral guide pin allowed the handle to be stowed sufficiently to enable the door to be closed with minimal force.

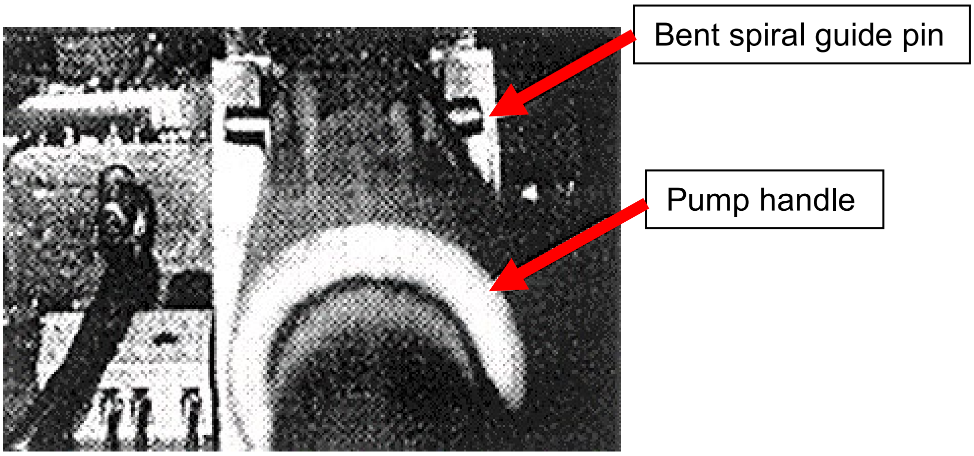

Figure 16 - Wrong side failure example

The closed door applied enough force to the pump handle to cause the spiral guide pin to ride up the step in the guide slot. The bent spiral guide pin allowed the handle to travel just far enough to open the HSL valve. The barrier commenced to lower as expected.

However, as the barrier lowered, the tilting movement of the power pack / ram assembly negated the force applied to the pump handle.

The spiral guide pin dropped down the step causing the HLS valve to close and the barrier stopped lowering.

Other castings have been inspected and found to have similar steps. However, the height of the step was not constant due to the machining tolerances and the width of the cast slot.

Excessive wear on the lower face of the machined slot could increase both the height of the step and the risk of the handle not fully seating at the bottom of the slot.

The machines most at risk are those fitted with booms in excess of 7600 mm (pivot to tip). In these cases, the long stroke coupling position is used which tilts the power pack further from the door check bracket.

In this position the clearance between the closed-door check bracket and the pump handle is increased comparative to that when the “short” stroke position is used.

7.15 Main Shaft Movement

A Wrong Side Failure occurred when a barrier remained in the raised position throughout the crossing sequence. The main shaft had moved through the bearings causing the machine components to come into contact with each other and obstruct the operation of the barrier.

In this case the probable cause was a severe blow to the end of the main shaft. However, the inspection revealed other potential failure conditions affecting BR Spec. 843 machines manufactured by both G.W.E. and Smiths Industries.

In a number of machines manufactured by G.W.E. the main shaft bearings were found to be loose. This made it possible for the rotating shaft to move through the bearings during the barrier operating cycle. The lateral movement would have caused the machine components to foul each other preventing the correct operation of the barrier.

Some machines manufactured by Smiths Industries were found to be slow in operation, which is a potential Wrong Side Failure condition. The cause was attributed to the main shaft bearings being over tightened during manufacture.

In both cases, personnel trained in the use of the special tools required undertook the rectification.

The above conditions should not re-occur. However, if movement of the main shaft is found or suspected, or the specified operating times cannot be achieved when the machine is set up correctly, the cause might be one of the above. It is stressed that adjustments shall not be undertaken locally unless the staff have been trained and the special tools are available.

7.16 Field & Grant Circuit Controller

The type TY 199 group 5 circuit controllers fitted to barrier machines during manufacture or supplied direct from the manufacturer as service replacements from 1996 are pre-set in compliance with BR Spec. 843 and do not require on-site coarse adjustment. However, fine adjustment might be necessary to compensate for local site variations such as site foundation levels, road profiles, or boom lengths.

Where site conditions require fine adjustment of the circuit controller proceed as follows:

a) Open the lid of the circuit controller.

b) Identify the band that requires adjustment.

c) Loosen the nut on the terminal stud just enough to allow the spring contact finger and its associated adjuster to be moved.

d) The adjuster is located into one of seven holes in the contact spring and is to be disengaged to permit the contact spring to be moved.

NOTE: *Very fine tuning can be achieved by moving the adjuster tip in the free space within the original hole in the contact spring. (particularly useful on long WR style booms).*

e) The contact spring has a slotted fixing hole and can be moved in the required direction to achieve the correct setting.

f) Re-engage the adjuster into the next available hole in the contact spring.

g) Carefully tighten the terminal nuts verifying that the contact spring and wire terminations are secure.

h) Test for correct operation.

i) Repeat the above procedure as necessary until the operation is correct.

j) Close and secure the circuit controller lid.

If the circuit controller springs are excessively worn, have lost tension are corroded or have fractured, replacement of the complete controller is recommended as good practice rather than changing the contact springs.

A heavily worn or grooved band is indicative of incorrect spring tension, maladjustment, or malformed springs.

The complete controller should be replaced.

The sleeve is an "Oilite" bearing which continually lubricates throughout the life of the unit. The cover of the modified units carried the letter "P" or "R" adjacent to the logo to aid identification.

The "R" type is fitted with larger spline collars which are coloured red instead of black. Labels with the legend "DO NOT OIL" are fitted to the bearing housings.

Although the type "R" is the latest version, either "P" or "R" types can be fitted.

For optimum performance, the "Oilite" type of bearing relies on 360° rotation of the shaft to distributed the lubricant evenly. However, in this design of circuit controller full rotation does not occur and can result in inadequate distribution of the lubricant and bearing failure.

The end of the bearing nearest the operating arm is also exposed to the atmosphere. In some instances, the lubricant has been found to dry up causing the bearing to seize on the shaft.

The dried lubricant / dirt contamination might appear as a black or brown film in the area of the bearing. However, this is not always visible until the unit is dismantled. If a faulty circuit controller is thought or found to be the cause of slow or faulty operation of the barrier equipment, a replacement controller is the only option.

It is stressed that the "Oilite" type of bearing shall not be lubricated, internally or externally otherwise the porous bearing material can become clogged.
A faulty bearing cannot be rejuvenated and a good bearing might fail prematurely. "Elvolube" contact lubricant contains oil and has a similar affect, it is emphasised that excess lubricant or spillage shall be carefully removed.

7.17 Hydraulic Ram Failures

There have been instances where the hydraulic ram has broken at the upper trunnion block end.

This defect was "masked" by the barrier continuing to operate by driving along the inner face of the pedestal front door.

The fault only comes to light when the front door is opened with the boom in the raised position. Once the door is opened the hydraulic unit is free to fall forward and the barrier falls, uncontrolled, on to the person opening the door.

This issue was immediately addressed by labelling the front door instructing not to be opened with barrier raised.

Later hydraulic units have ram modifications to eliminate this mode of failure.

8. Rural Barriers

8.1 General Description

The rural barrier apparatus usually encountered on the railway was manufactured by Godwin Warren Engineering (G.W.E.). The G.W.E. rural barrier has now been superseded by a version of the Standard Lifting Barrier machine manufactured to BR Spec. 843 by Smiths Industries.

The level crossing barriers are normally in the lowered position and the crossing may also be protected by miniature warning lights or miniature stop lights.

Telephones connected direct to the adjacent signal box or other monitoring point are provided for the crossing user. Operating instructions are displayed on a sign fitted to the side of the machine housing on the approach side of the crossing.

The barriers are raised by the user applying a pumping action to the long handle on the exterior of the machine. Approximately 14 full strokes of the handle are required to produce enough hydraulic pressure to completely raise the barriers.

The BR Spec. 843 machine requires approximately 14 to 24 strokes.

Lifting a small lever on the opposite machine lowers the barriers. Operation of the lever releases a valve causing the hydraulic fluid to return to the reservoir ready for the next operation.

The crossing user is responsible for the correct operation of the equipment, their own safety, and that of others, by lowering the barriers after use.

If the barriers are left raised it might be thought that it is safe to cross and could result in an accident.

Instances of the barriers being left in the raised position, especially if it is a common occurrence at a particular crossing, shall be reported to your manager so that action can be instigated.

8.2 Faulty Operation

The hydraulic system of the G.W.E. rural barrier is a relatively simple design. However, for optimum operation of the system, the reservoirs should be at the same height and the return pipe run below the oil level of the reservoirs throughout its length.

If, due to the profile of the crossing area, the barrier machines are installed at different heights, the variation in reservoir height and associated fluid level can affect the rate of the return flow to the higher reservoir.

The problem could be accentuated when the barriers are repeatedly operated from the same side of the crossing without a significant time delay between operations. The length, gradient, and height of the return pipe can also affect the return cycle of the hydraulic oil.

The fault can self-rectify if enough time has elapsed and therefore the reported barrier malfunction can be difficult to trace.

In severe cases, the combination of excessive use from one side of the crossing and an air lock or restriction in the balance pipe might cause the hydraulic oil to overflow from the lower reservoir whilst starving the higher reservoir. See '8.3 Air in the System'.

8.3 Air in the System

Pump the barriers to the fully raised position usually 14 full strokes are required for the GWE type. The machine derived from the BR Spec. 843 machine needs approximately 40 full strokes.

Lower the barriers and note the lowering time (usually 6 seconds). Both barriers should lower together, although the barrier of the machine at which the lowering lever was operated might tend to lead the other barrier.

If the barriers of the GWE type machine lower slowly check that the bleed valve jet on the ram is clear.

8.4 Bleeding Air from the System (G.W.E. Type)

Hold down the lower release valve and pump air through into the reservoir. Repeat the procedure from the other barrier machine. Loosen the bleed valve at the top of the ram and allow any trapped air to bleed off. Repeat the procedure for the other barrier machine ram.

To check that air is expelled when refilling the system with hydraulic fluid it is necessary to pump through the main pressure feed pipe. To do this, disconnect the pipe from the master barrier and pump fluid through the slave.

When connecting the main pressure pipe hold down the lower release valve and pump the air through into the reservoir, as previously described.

8.5 Bleeding Air from the System (BR Spec. 843 Type)

The ram body incorporates an air bleed groove which allows any air trapped below the piston to escape to the reservoir when the ram is caused to over travel before installation in the pedestal.

If it becomes necessary to bleed the system, the ram top pivot bracket shall be disconnected from the operating arm to allow the ram to over travel and note which fixing holes are used. (Unused holes are usually blanked with bolts and nuts painted red).

a) Keep the unit in the upright position and use the manual pump handle to fully extend the ram. Continue the pumping action to cause the ram to over travel and the air to return to the reservoir.

b) Reconnect the ram top pivot bracket to the original holes in the operating arm.

c) Raise and lower the boom 2 or 3 times and check that the machine operates correctly.

d) The barrier should rise smoothly without hesitation and should not oscillate excessively during the last few degrees of travel.

e) Check the level of the hydraulic oil, top up as necessary. The oil should be just visible in the filter strainer.

f) Replace the filler cap securely.

g) Repeat the procedure for the other barrier machine.

9. Western Region Barrier

9.1 Hydraulic Ram Setting

The correct height at which the lowering barrier is damped is reliant on the dimension between the centres of the barrier pivot and the bottom ram pin. This dimension is 891 mm (2 ft 111/16 ins).

The dimension between the centres of the top and bottom ram pins is 1021 mm (3 ft 43/16 ins) and can be used for the initial setting. See Figure 17.

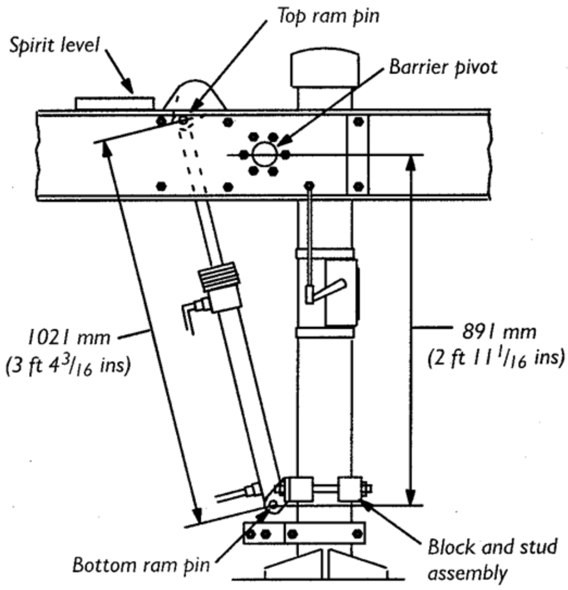

Figure 17 – Hydraulic Ram Setting

Checking this dimension is difficult due to the restricted working area. A simple gauge can be made from an old locking bar and the driving tips from two copper earth rods, See Figure 18.

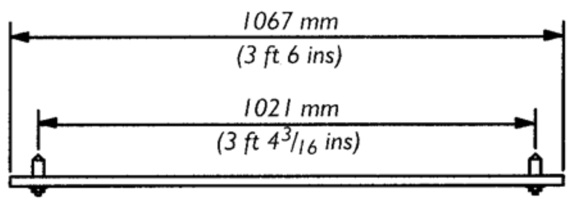

Figure 18 – Dimension Gauge

Cut the bar to length and carefully remove all burrs and sharp edges. Take great care when marking out the position for the two holes for the locating pins (driving tips).

Punch the hole centres and drill through with a sharp 9.5 mm (3/8 in) drill. Assemble the tips to the bar and secure with M10 nuts and washers.

With the barriers in the fully lowered position, check that the barrier is horizontal by placing a spirit level on the top of the side arm channel that carries the boom. See Figure 17.

Wipe each grease nipple and the end of each ram pin before removing the grease nipples. Check they are kept clean prior to refitting when the check is completed.

Check that the tip ends of the gauge are clean and free from dirt. Try to locate the tip ends into the grease nipple holes in the ram pins. If the dimension is correct, they should fit centrally in the holes. If not, adjustment could be required.

This can be achieved by moving the clamp blocks and bottom ram pin bracket assembly, as required. When the dimension is correct, secure the assembly, and re-check the dimension.

If still correct, check that the grease nipples are clean and re- fit them. Replenish the lost grease using a grease gun filled with lithium based grease.

Test the barrier to verify that it operates correctly. Operate the barrier several times to clear any air from the hydraulic system before finally checking the damping action as the barrier lowers.

The barrier should be damped when the tip is approximately 914 mm (3 ft 0 ins) from the road surface. If the damping is incorrect further adjustment may be necessary. Failure to achieve the correct setting may be due to movement of the clamp blocks. See ‘9.2 Bottom Clamp Block Movement’.

9.2 Bottom Clamp Block Movement

During 1977 the bottom clamp block and “U” bolt assembly which also secures the bottom ram pin bracket to the post was replaced with two blocks. The “U” bolt was replaced with two ¾ inch x 10½ inch studs with a ¾ Whitworth thread at either end. Each stud end was fitted with a plain washer, spring washer, and nut.

At some installations the clamp blocks and bottom ram pin assembly moved during operation of the barrier. The movement altered the setting of the ram length dimension and the position at which the barrier was damped as it lowered. The blocks were not securely clamped to the post due to insufficient length of thread on the studs. Although the nuts were fully tightened, they had only “bottomed” on the end of the thread.

If the correct clamping position cannot be maintained, movement of the clamp blocks could be the cause. Fitting additional washers may prove a temporary cure until the faulty studs can be replaced.

Some machines are fitted with a bar between one leg of the lower “U” bolt that secures the barrier pivot bracket to the top of the post and one of the studs that secures the clamp block and bottom ram pin assembly to the bottom of the post.

This was a local modification to address the problem of clamp block movement. However, the bar should not be necessary if the stud thread lengths are correct and a plain and spring washer is fitted beneath each nut.

9.3 Ram Pin Failure

An investigation into the failure of a Western Region type barrier revealed that the top ram pin had broken in half.

In this condition the retaining cotter pin was rendered ineffective allowing the broken ram pin to fall out. The hydraulic ram became detached from the drive lugs of the side arm cross member (rear strut).

This failure occurred with the barrier in the fully lowered position. If the pin had failed during the operating cycle only the counterbalance weights would have prevented the barrier falling without warning.

In high wind conditions the counterbalance forces might not be enough to prevent such an occurrence. Similarly, if the counterbalance weights are not at the optimum setting the result could be the same. In either case a serious accident or injury could occur.

9.4 Top Ram Pin

Lubricant is delivered to the bearing surface via a longitudinal hole drilled along the axis of the pin. A countersunk cross drilled hole connects this gallery with an annular groove at the centre of the pin. See Figure 19.

NOTE: *The following illustrations derived from drawing F1A2239/I5, have been exaggerated for clarity, and are not intended for manufacturing purposes.*

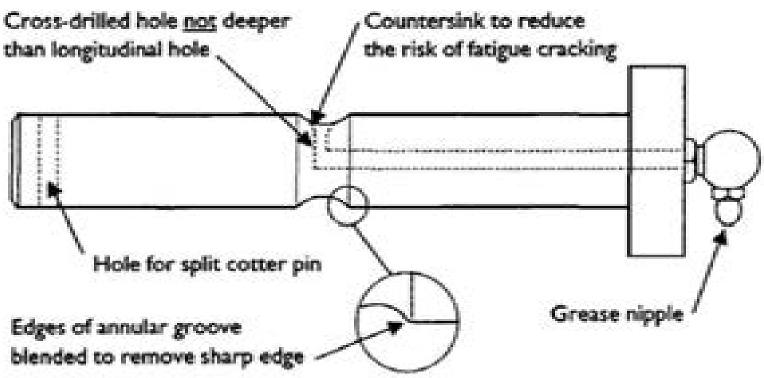

Figure 19 – Correctly manufactured ram pin

10. CLOSED CIRCUIT TELEVISION (CCTV)

10.1 Camera Column (Code of Practice)

The winch mechanisms and ropes used on camera columns should be inspected at regular intervals. This work is done by plant staff who work to NR/L2/ELP/27238 Appendix L.

END

General

Point rollers are designed to assist the movement of the switch rail during the operation of points by reducing the effects of friction. This leads to a reduction in the amount of drive force that is required to operate the points hence reducing the wear on the asset.

The point rollers are adjusted to achieve the minimum amount of lift of the switch rail as quickly as possible during the movement of the switch rail.

If the point rollers are set too high then the point operating equipment has to work harder to lift the switch rail higher than what is required, which leads to an increase in drive forces.

If the point rollers are set too low, then there will still be issues associated with the friction between the switch rail and the slide baseplates, also leading to an increase in drive forces.

Due to the condition of the switch rail i.e. hogging or differing track conditions, the rollers might require adjusting from their optimum setting in order to maintain reliable operation of the point operating equipment.

When the rollers are set to the correct height, it should be possible to slide a 1mm feeler gauge between the bottom of the switch rail and the slide baseplates.

If point rollers are set to a height to accommodate poor switch rail or poor track conditions, there will be a need to reset the position of the point rollers if any track improvement work is carried out (eg. tamping, stone blowing, or lifting and packing) as the relationship between the bottom of the switch rail and slide baseplates will be altered.

Point rollers might also need adjusting due to changes in track condition over time caused by the passage of trains.

Where points are fitted with Remote Condition Monitoring equipment, this should identify where the point rollers are not operating correctly. Also, it should be possible to compare current traces from before and after adjustment to make sure that the point roller adjustment has been effective.

Setting Up Point Rollers

Adjustment of the rollers should be done if they are out of position due to:

- Back Drive adjustment
- Manual Lift & Packaging
- Tamping or Stone Blowing

On Hy-Drive mk2 installations, the rear rollers might need to be lowered to allow manual pumping of the points due to the back of the switch starting to move before the toe leading to the lock arm jamming.

The height of the rollers can only be set when the switch rail is in the closed position.

1.1 Check to see that the switch is fitting up with the stock rail. If this is not the case then the back drive may need to be adjusted before the point rollers are set up.

For each roller assembly:

1.2 Clean the slide / base plates of dust and debris and remove the fixing bolts from the roller package.

It is good practice to grease the holes that are not used with lithium grease to prevent the threads from rusting (see figure 1).

Figure 1 – Grease Holes

1.3 Check the condition of the thread on the fixing bolts, replace them if necessary.

1.4 Place the fixing bolts back onto the roller package, before tightening lower the roller assembly to the lowest setting and slide the roller package horizontally underneath the rail.

1.5 Adjust the height of the roller so it comes into contact with the bottom of the switch rail (see figure 2); make a note of the height.

Figure 2 – Grease Holes

1.6 Slide the roller package out from under the switch rail and raise the roller assembly by 1mm.

1.7 By using a feeler gauge, measure the gap between the bottom of the switch rail and the slide plate (see figure 3), this distance will be known as 'X' mm during the following set up procedure.

Figure 3 - Gap

1.8 Slide the roller package horizontally underneath the switch rail allowing a gap equal to 1mm + 'X' mm to accommodate dynamic loading.

1.9 If a second roller is present, then set the second roller 1mm higher than the first.

1.10 Tighten the fixing bolts to 70NM by using the torque wrench, then recheck the height of the roller assembly as it may have moved in the tightening process.

1.11 Repeat the process for all roller packages throughout the closed switch.

1.12 Check the roller height settings (see figure 4). If they are approaching their maximum height setting, this should be reported to your supervisor as corrective maintenance such as lifting and packing might be required.

Grey roller packages provide a lift upto 6mm whereas blue packages provide a lift upto 4mm.

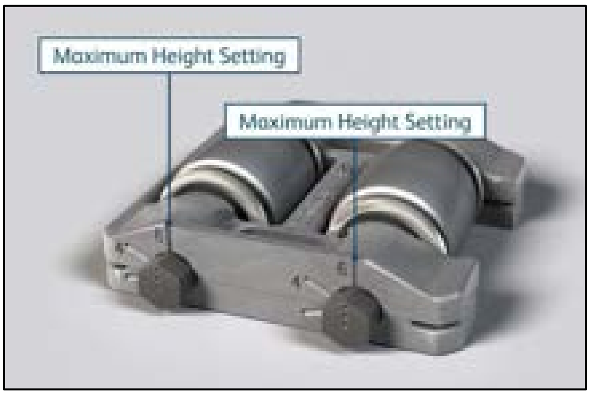

Figure 4 – Height setting

1.13 Operate the switch into the open position so the switch rail moves across the rollers.

1.14 Check the clearance between the bottom of the switch rail and slide baseplates through the switch lengths (see figure 5) . Ideally this gap should be between 1-3mm.

Figure 5 – Clearance check

1.15 If the 1mm clearance has not been achieved then raise the height of the roller, if the clearance is greater than 3mm then the height of the roller shall be reduced.

1.16 Recheck all slide plate clearances are within 1–3mm, if not then readjust.

1.17 Check that the kicking strap has a 6-9mm clearance from the stock rail.

1.18 Once all rollers have been set, operate the switch over and back a few times and assess the roller operation.

1.19 Check for signs of binding.
If the kicking strap is binding and this cannot be adjusted at the time of the roller setup, the front rollers can be lowered whilst arrangements are made to adjust the kicking strap. This should be reported as corrective maintenance.

1.20 Check the switch and rollers function normally after all work has been completed. Any issues that could not be rectified should be reported to a supervisor.

Further details of how to set up the rollers can be found in the standardised task video found on the Network Rail Intranet and How To app.

END

1. Mil Spec 5015 Plug Couplers, General

1.1 Mil Spec 5015 Plug Couplers (Figure 1) are defined in Network Rail standard NR/L2/SIG/30027 and consist of a plug and a receptacle which mechanically lock together via a reverse bayonet fitting.

Figure 1 - Mil Spec 5015 Plug Coupler. Male (left) and female (right)

1.2 Cables are supplied as pre-fitted “sealed units” with plugs/receptacles.

1.3 Maintainers shall not attempt to re-terminate plugs or receptacles.

1.4 A receptacle will typically be provided on lineside equipment by being mounted in the equipment’s housing. Alternatively, the equipment can be fitted with a receptacle on a cable, which is then wired into terminals in the equipment.

1.5 5015 Plug Couplers are supplied with an environment cap to stop contamination of both pins and sockets. See Figure 2.

Figure 2 - Plug Coupler with (detached) environmental cap

2. General Maintenance

2.1 MIL 5015 connectors do not need scheduled maintenance and should not be disconnected during routine maintenance. Routine examination is limited to visual external inspection for signs of damage to the connector/cable boot and incorrect alignment/incomplete locking. It is not necessary to lift troughing etc to inspect inaccessible plug coupled joints.

2.2 Figure 3 shows the locking mechanism in both the locked and unlocked positions.

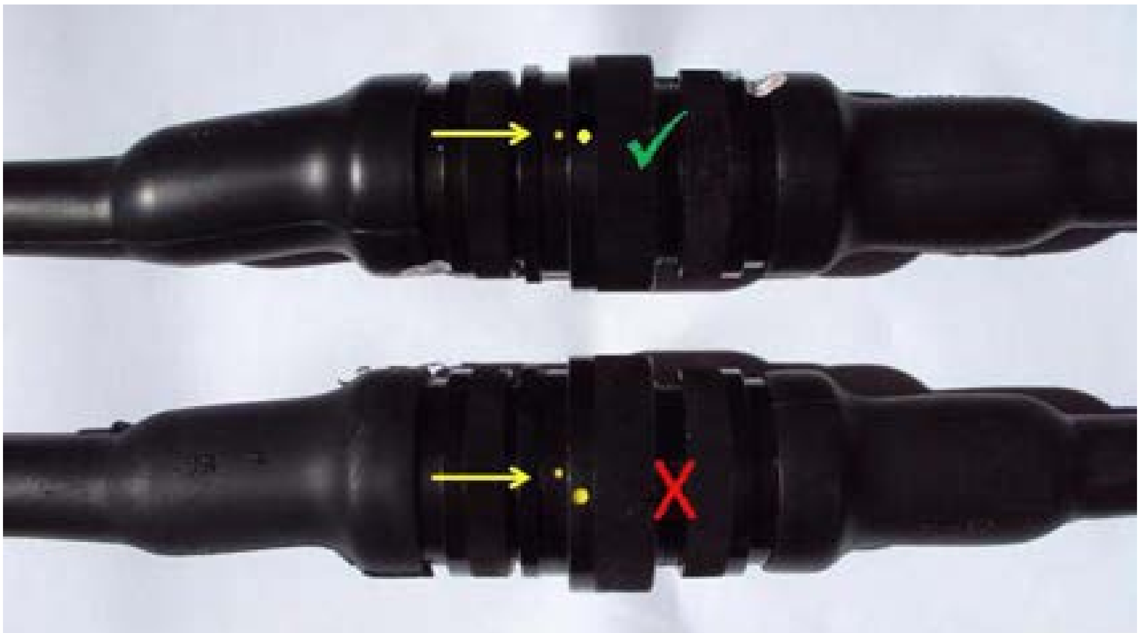

Figure 3 - Plug Couplers showing correct (top) and incorrect (bottom) mating. Note the position of the alignment dots

2.3 If required, disconnect the equipment using links at the location case where possible, not at a plug coupler.

3. Faulting

3.1 Where possible, plug coupled connections should not be opened and instead diagnostic testing should be done from accessible termination points such as Wago links in the location case/ REB. This will enable testing through the plug coupled connector.

3.2 When disconnecting plug coupled connectors, connect an environmental cap to both connectors except when connected to a break out box.

3.3 If environmental caps are not fitted to any exposed connectors i.e. plugs or receptacles, then NR/SMTH/Part04/CA06 (Renew a Plug Coupled Cable ("interconnect") with a Non Certified Replacement) testing shall be required following reconnection.

3.4 A Product Approved breakout box can be used to connect in-line across the plug coupled connections so that test terminals are available.

3.5 A pre-use test of the breakout box shall be carried out in conformance with the manufacturer's instructions.

This enables continuity and insulation resistance testing to be carried out on plug coupled equipment and cables.

3.6 Test Leads SHALL NOT BE INSERTED INTO MIL SPEC PLUG COUPLER PLUGS OR RECEPTACLES WHETHER MALE OR FEMALE UNDER ANY CIRCUMSTANCES.

They might damage the pins/sockets and potentially cause short circuits between cores. Damage inflicted in this way may not be visible to the naked eye.

3.7 Before (re)connecting plug coupled equipment, the Maintainer shall visually check that the plug coupler has not been damaged and that there is no water ingress. If there is, then the affected cable ("interconnect") or equipment shall be replaced.

END

GENERAL

DO NOT INSERT TEST LEADS INTO MIL SPEC PLUG COUPLER PLUGS OR RECEPTACLES WHETHER MALE OR FEMALE UNDER ANY CIRCUMSTANCES since these might damage the pins/sockets and potentially cause short circuits between cores.

INTRODUCTION

Where it is essential to record test measurements at the plug coupler then an approved break out box should be used. This enables continuity and insulation resistance testing to be carried out on plug coupled cables. Some break out boxes can also be inserted at an inline plug coupler so that ‘on load’ voltage can be measured across plug coupler pins.

There are currently a number of prototype break out boxes in service see Figure 1:

Figure 1 – Break Out Box

1. Signal Maintenance Testing

1.1 A product approved breakout box can be used to connect in-line across the plug coupled connections so that test terminals are available. However, if possible, testing should be done from accessible links to avoid the need to open the coupler.

2. Signal Works Testing

2.1 Where an approved break out box is required for testing it shall be stated in the relevant test specification. If it is not specifically identified, then authorisation for its use is referenced in the test instruments section of the test plan.

3. Before Use

3.1 Inspect that the break out box and its components are not damaged.

3.2 Check all end caps have been correctly fitted.

3.3 Remove each cap and inspect each connector to check that there is no damage visible to the pins or sockets.

See Figure 2 and Figure 3 for the type of damage that might be present:

1. Fig 2 a socket has pushed back into the housing.

2. Fig 3 three pins have been pulled forward. No pin shall stand proud of it housing for safety reasons:

Figure 2 – Socket pushed back

Figure 3 – Three pins pulled forward

3.4 Check that the unit has a valid certificate of conformance or an equivalent label attached.

Any deficiencies found shall be reported to the Tester in Charge or the SM(S).

4. Connecting the break out box

4.1 The break out box is configured in pairs of receptacles (R) and Plugs (P).

4.2 Each pair has a numerical ID e.g. R1 and P1.

Pair ID	Insert Arrangement	Number of cores	Plug Type	Receptacle Type
P1 / R1	32 - 013	12	Male	Female
P2 / R2	32 - 013	10	Male	Female
P3 / R3	24 - 2	7	Male	Female
P4 / R4	20 - 4	3	Male	Female
P5 / R5	20 - 4	3	Female	Male

Table 1 – Break out box 1

Pair ID	Insert Arrangement	Number of cores	Plug Type	Receptacle Type
P1 / R1	32 - 013	10	Male	Female
P2 / R2	20 - 23	2	Male	Female
P3 / R3	20 - 4	4	Male	Female
P4 / R4	20 - 4	4	Female	Male
P5 / R5	20 - 4	2	Male	Female

Table 2 – Break out box 2

4.3 Figures 4 shows the Break out Box with environmental covers in place, and Figure 5 shows Environmental covers removed and the Break out Box in use.

Figure 4 – Break Out Box with environmental covers in place

Figure 5 – Break Out Box in use

Insert arrangements are made of two numbers the first being the coupler size and the second being the pin configuration. When looking at the pin configuration blank or removed pins should be taken into consideration.

4.4 Identify the cable to be tested is correctly labelled, of the correct type and that the plug coupler is of the correct size.

4.5 Visually check plug coupler for signs of mechanical damage to connector shell/housing, contacts and that all contacts and filler plugs are inserted correctly.

A break out box shall not be inserted into a circuit until arrangements have been made with the Signaller to book the circuit out of use for testing purposes.

4.6 Check that the relevant arrangements are in place prior to disconnecting any operational equipment.

5. Voltage Check

5.1 For ‘on load’ voltage testing the plug coupled connection needs to be uncoupled and the male and female connections need to be connected either side of the breakout box using the relevant pair of connectors, as shown in Figure 6.

5.2 Check that both Mil 5015 connectors visually, mechanically and audibly secured.

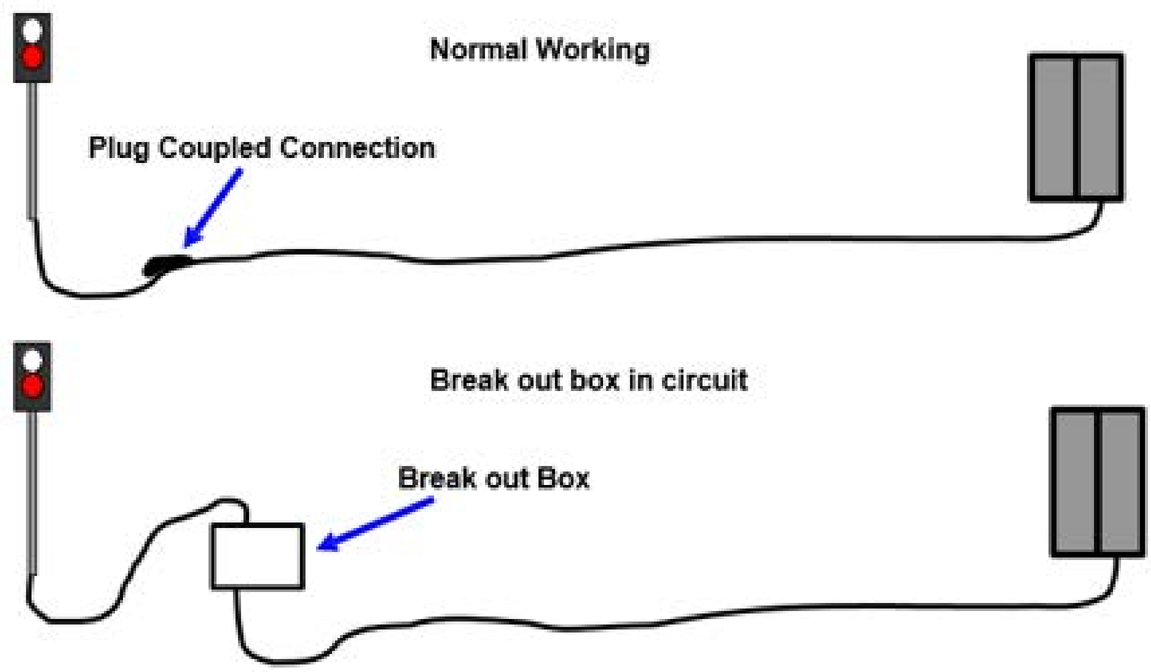

Figure 6 – Inserting a break out box for on load testing

5.3 At this point all of the cable cores are available for via the 4mm plug sockets mounted on the top of the breakout box. These should be used in the same way as if the interconnect was terminated on links. Multiple testing methods can now be employed.

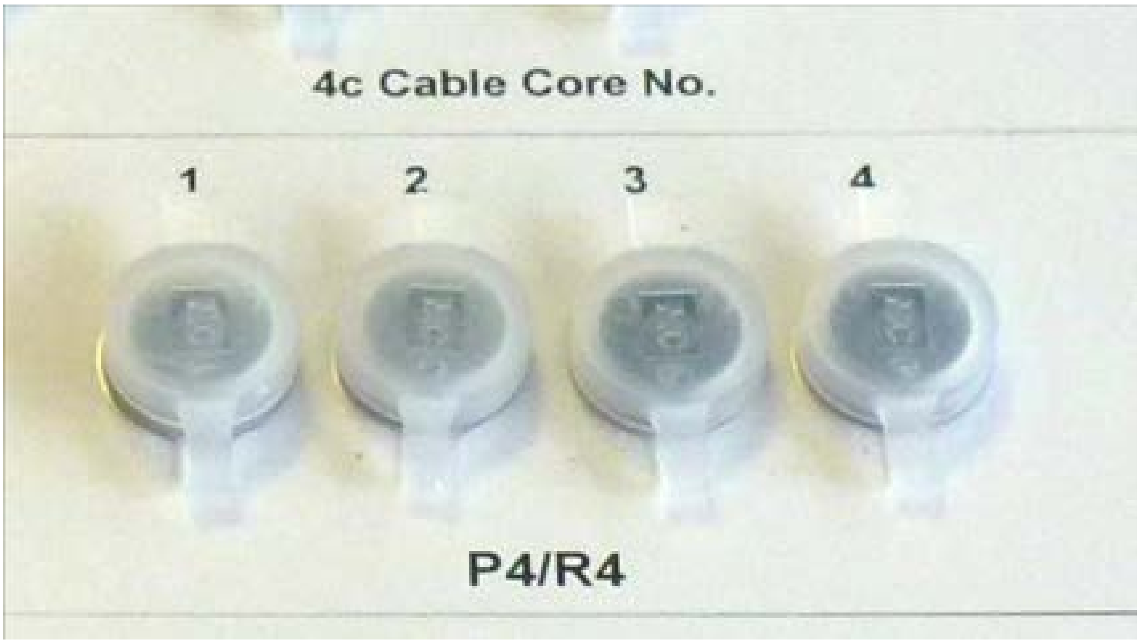

Figure 7 – Break out box sockets

5.4 An example of the 4mm sockets found on the Break out box, associated with a 4 core interconnect/cable, can be seen in Figure 7. Each of the four numbers relate directly to the cable core number.

5.5 By plugging a meter into the relevant test sockets voltages can be measured.

6. Testing for Current

6.1 This test can only be carried out on a two-core cable and would normally only be used to test an AWS.

6.2 On both break out boxes there is a facility to undertake a current reading.

6.3 Break out box 1 has the facility to test only one of the possible connector sizes whereas Break out box 2 caters for both sizes of connector.

6.4 The terminations for the two cored cables differ from all others by having two core one 4mm test sockets.

6.5 With the break out box in circuit and the meter set to read current, the meter leads should be plugged into the 2 terminations marked 1, see Figure 8.

Figure 8 – Current Testing

6.6 Check the circuit being tested is energised and when ready to take the current measurement press the green push button on the front panel.

6.7 Pushing this button inserts the meter into the circuit between the number 1 pins of the connected inline couplers, see Figure 9.

Figure 9 – Current Testing Push Button

6.8 Record readings as required then release the push button

7. Continuity and Insulation Tests

7.1 To carry out both of these tests, a break out box for each plug coupled interconnect end is required.

7.2 Where an interconnect is plugged into a wire receptacle which is then terminated directly onto disconnect able links it is acceptable to test through the interconnect as far as the links.

7.3 Both CONTINUITY TEST and INSULATION TEST shall be carried out as laid down in the defined tests.

8. After Use

8.1 Check that all the plastic test socket covers are correctly re-inserted.

8.2 Check that all the coupler caps are correctly reconnected.

8.3 Where provided, replace the break out box into the carry bag/case.

END

1. Frauscher Advanced Counter FAdC, General

The FAdC is used for safe monitoring of track sections. With the FAdC, the clear and occupied status can be generated by the track sections. The clear and occupied status is output by the software interface or by voltage-free relay contacts. One track section can consist up to 16 counting heads. A counting head consists of a wheel sensor (RSR123), an overvoltage protection unit (BSI005) and an evaluation board (AEB). Double or multiple usage of a counting head is possible.

The FAdC may either be connected to a CAN bus or decentralised across large distances using an Ethernet network.

2. Operating mode of the FAdC

At the start and end of each track section, there is a wheel sensor that acts as a counting head together with the BSI and the AEB. This detects all the axles of rolling stock travelling on this track and also their direction of travel, using two electronic wheel sensor systems. By comparing the counting result for the axles counted in with the result of those counted out, it is possible to make a statement regarding the status of the track section.

Each wheel sensor is connected with an AEB by a four-wire signal cable. This connection provides the power supply to the wheel sensor and transmits the axle information to the AEB. The AEB boards are linked with one another by means of a CAN bus.

An AEB correlates the axle information for all counting heads allocated to a track section into an overall result and uses this to create a clear or occupied indication for this track section.

The COM-AdC or the COM-WNC, which are also connected to the CAN bus, provide an Ethernet interface. Using this interface, the clear and occupied indications can be output via a vital protocol (COM-WNC), for any further processing required. Alternatively, the clear and occupied indications can also be output via voltage-free relay contacts from an IO-EXB connected to the AEB.

3. Test equipment

The following items are used to complete all the testing and maintenance activities on Frauscher Advanced Counter equipment:

- Testing plate PB200.
- Advanced Service Display ASD and Service Display Cable.
- Frauscher Diagnostic System FDS (optional).

- Multimeter, range 1000 mV DC, ± 0.5 % basic accuracy, internal resistance >> 1 kΩ.
- 2 leads with 2 mm male connectors.
- Non-conductive cord.
- Tape measure.

4. Wheel sensor RSR123

The wheel sensor RSR123 detects axles and consists of two sensor systems. Viewed from the plug side, wheel sensor system 1 is on the left hand side, wheel sensor system 2 is on the right hand side. Wheel sensor system 1 and 2 are symmetrically in design and are galvanically separated. Two wires are allocated to each wheel sensor system. On the wheel sensor there is a four-wire cable connected via a plug connection, with a standard length of 5, 10 or 25 m. It is recommended to use a protection tube for the cable.

Figure 2 - RSR123 Wheel Sensor

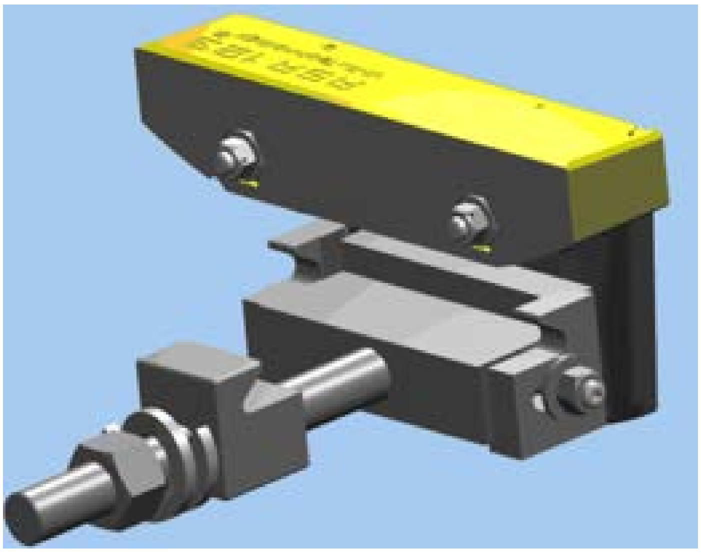

Figure 1 – RSR123 Wheel Sensor Bracket

5. Communication Boards COM-WNC/COM-AdC

The hardware of the COM-WNC is identical with the COM-AdC. In addition to the functionality of the COM-AdC (configuration server and data transmission within the FAdC) the COM- WNC can communicate with an interlocking via Ethernet.

The COM-WNC contains the protocol implementation for the interlocking specific protocol WNC. So, the COM-WNC enables to convert data of the FAdC with the protocol FSC to the protocol WNC of the interlocking and the data of interlocking with the protocol WNC to the protocol FSC of the FAdC.

Figure 3 - COM-AdC Card

Indication/ Function	**Meaning/Use**
Serial Interface	Service Interface (for ASD)
PWR	Power supply
Status Card	Status display (flashing in the event of a fault).
CAN	Illuminated when CF card is present and ok, flashing in case of card access
	Illuminated when software-configuration is obtained, illuminated or flashing in the event of a fault
Ethernet 1	Connection to network 1
Upper LED	Illuminated when a connection to the network is present.
Lower LED	Flashes when data is transmitted or received
Ethernet 2	Connection to network 1 or 2
Upper LED	Illuminated when a connection to the network is present
Lower LED	Flashing when data is transmitted or received
Stop	No function at present
Run	No function at present
Type key (on the top of the hand grip):	
COM-AdCnnn	Board identification code starting with 001
xx...yy	Operating voltage range
GSzz	Version beginning with 01

6. DIP-switches of the COM-AdC / COM-xxx

The DIP-switches can be found on the left-hand side of the COM-AdC/COM-xxx.

There two dip switches for each of the channels.

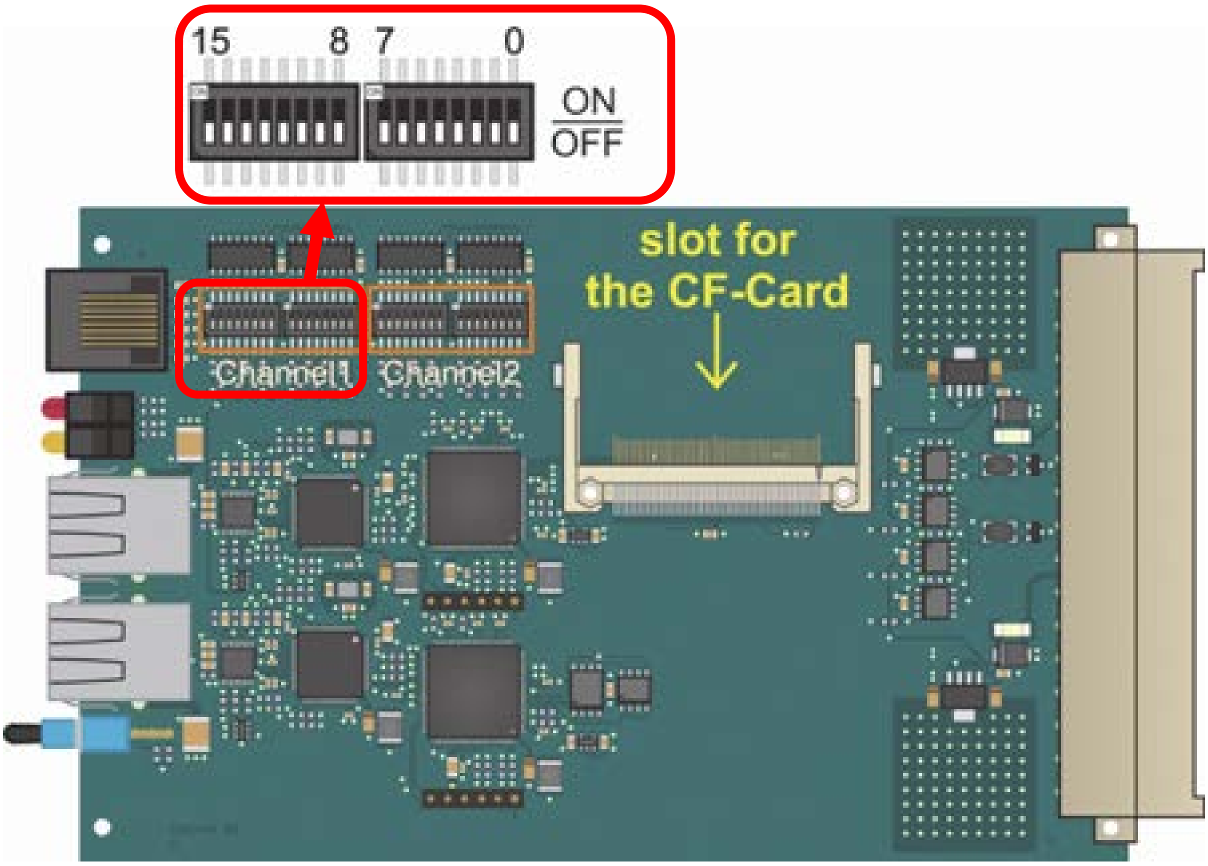

Figure 4 - COM-AdC Dip Switches

7. Advanced Evaluation Board AEB

The AEB is used to supply and evaluate a wheel sensor RSR123. The digital counting head information is output for further processing. Moreover, the AEB's tasks also include counting axles and generating failsafe clear and occupied indications for up to two track sections. An AEB can control up to 8 IO-EXB or 8 CO-EXB boards (the boards can also be used in combination).

Figure 6 – AEB Card

Indication/ Function	Meaning/Use
Serial Interface	Service Interface (for ASD)
PWR	Power supply
Sys1	System 1 occupied (illuminated) or faulty (flashing).
A1	Indicates the clear and occupied status of track section 1 and/or displays counting head control
B1	The AEB obtains its software- configuration (illuminated) or data transfer interfered (illuminated/flashing)
Adjust	Adjust Is required to adjust the wheel sensor / AEB and to carry out a pre-Reset
Test	Simulates damping of system 1
V+/GND	2 mm test sockets, voltage corresponds to the analogue wheel sensor current via an 100 Ω Shunt
PWR	Power supply
Sys2	System 2 occupied (illuminated) or faulty (flashing).
A2	Indicates the clear and occupied status of track section 2 and/or displays counting head control
B2	The AEB obtains its software- configuration (illuminated) or data transfer interfered (illuminated/flashing)
Adjust	Adjust Is required to adjust the wheel sensor / AEB and to carry out a pre-Reset
Test	Simulates damping of system 2
V+/GND	2 mm test sockets, voltage corresponds to the analogue wheel sensor current via an 100 Ω Shunt.
Type key (on the top of the hand grip):	
AEBnnn-1/-3	Board identification code starting with 001, -1 for RSR180, -3 for RSR123
xx...yy	Operating voltage range
GSzz	Version beginning with 01

8. DIP-switches counting head outputs of the AEB

The DIP-switches counting head outputs can be found on the left-hand side of the AEB.

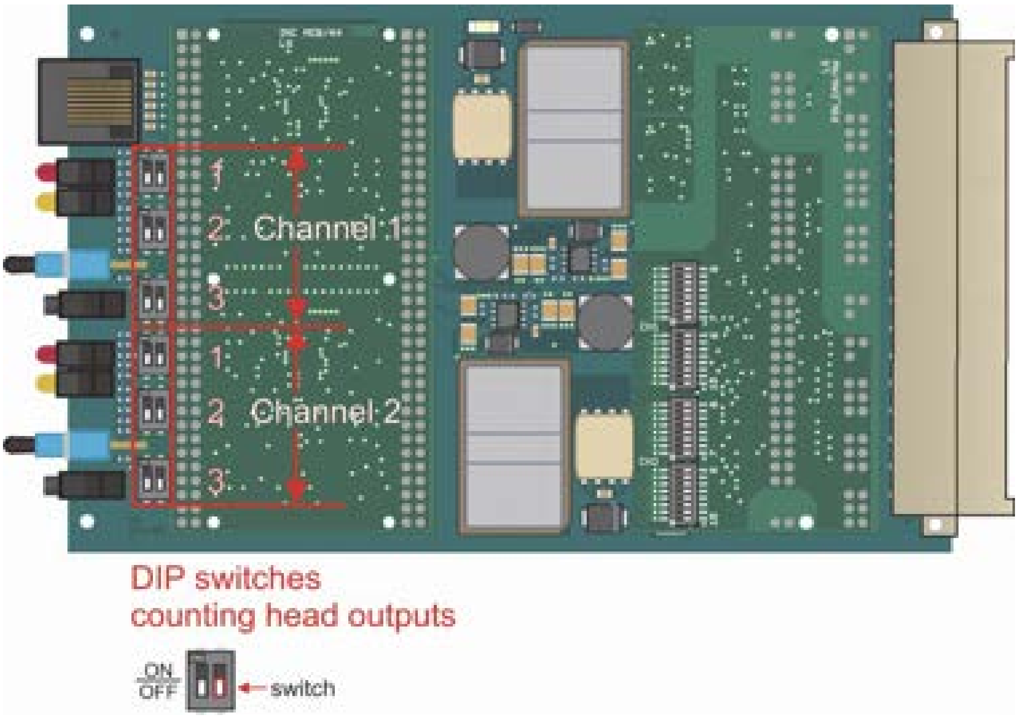

Figure 7 – DIP Switch Positions for Counting Head outputs on the AEB Card

9. DIP-switches ID of the AEB

The DIP-switches ID can be found on the right-hand side of the AEB.

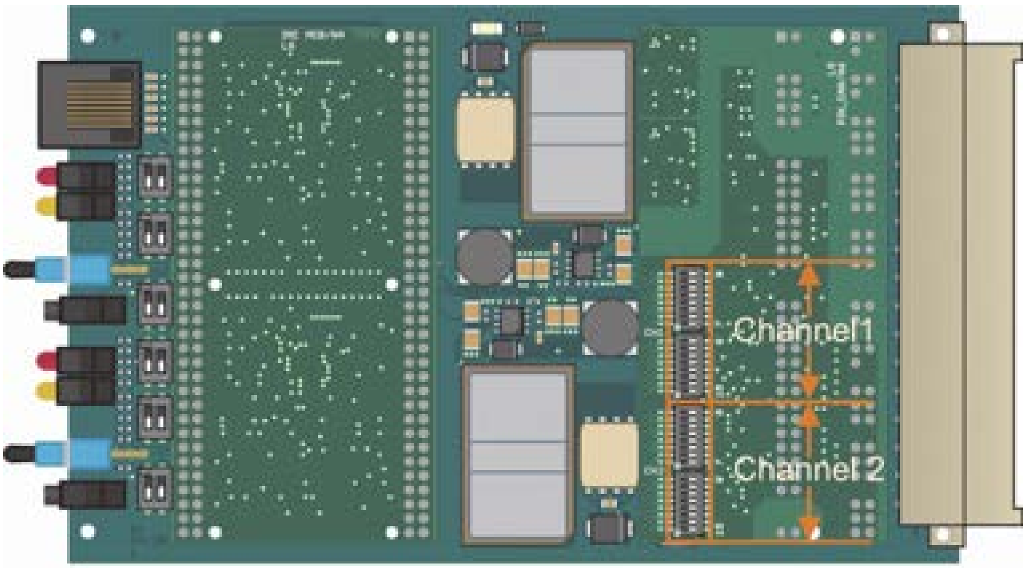

Figure 8 - DIP Switch Positions for the ID of the AEB Card

10. Input/Output Extension Board IO-EXB

The IO-EXB is used for failsafe output of the clear/occupied status for up to 2 track sections, via voltage-free relay contacts, and for output of error codes from the track section or the AEB. Alternatively, the IO-EXB can also be used to input and output failsafe and non-failsafe (depending on configuration) digital arguments (data transmission).

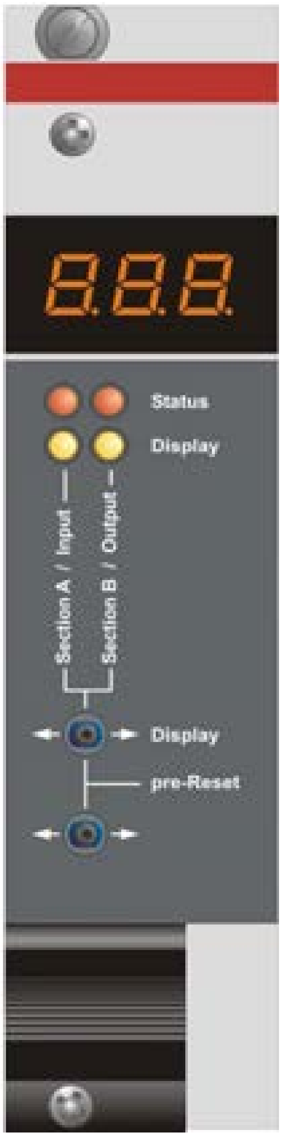

Figure 9 - IO-EXB Board

Indication/ Function	**Meaning/Use**
Display	Number of axles in a track section, Output of error code in the event of a fault, Output of the bit status as a HEX code (in the case of data transmission).
Status	Track section occupied (illuminated) or faulty (flashing). Output of the status of the inputs/outputs (flashing in the event of a fault, illuminated if no AEB is connected).
Display LED	Indicates the track section for which the information is valid, Track section 1 (= Section A) or track section 2(= Section B). These indicate which information (input or output) is currently valid on the display (in the case of data transmission).
Display button	Button to change the display between track section.
pre-Reset	Track section 1 and 2 or input and output Activated by pressing both buttons to the left (track section 1) or the right (track section 2) at the same time.
Type key (on the top of the hand grip):	
AEBnnn-1/-3	Board identification code starting with 001, -1 for RSR180, -3 for RSR123.
xx...yy	Operating voltage range
GSzz	Version beginning with 01.

11. Counting Head Control (CHC)

11.1 Counting Head Control (CHC) is a method of suppressing activation outputs of the RSR123 when no train is approaching.

Function:

a) CHC is active if both sections each side of the wheel sensor are indicating clear.

b) CHC is not active if one or both of the sections are indicating occupied (by a fault or a train) - any sensor activations will be passed to the signalling system.

Settings:

c) The number of outputs that can be suppressed is hard configured between 1 and 100, in a 1-minute period. After 1 minute the counter resets. If this count is exceeded the relevant sections will enter a failsafe state.

d) FAdC version R2 with AEB101 GS04 or later includes the facility to deactivate the CHC function. The method of deactivation/activation will be defined locally.

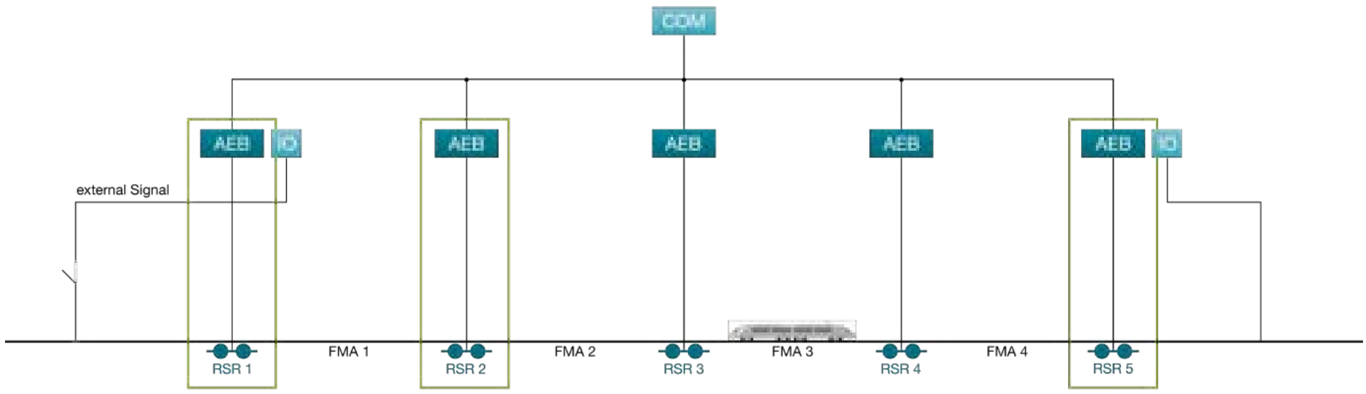

Figure 11 - Sensors with CHC active are highlighted in Green

12. Supervisor Track Section (STS)

12.1 A Supervisor Track Section STS is an additional track section covering two or more signalled track sections.

Function:

a) If the STS is clear, and one or both signalled sections are indicating occupied, then an automatic reset will be carried out on the signalled sections.

b) If both the signalled sections indicate clear, they are able to reset the STS.

Settings:

c) The type of reset is configurable (Unconditional/Conditional – with/without Sweep train).

d) The number of resets that can be carried out is hard configured between 1 and 100. The counter is reset with the successful traverse of a train. If this counter is exceeded a manual reset will be required.

e) FAdC version R2 with AEB101 GS04 or later includes the facility to deactivate the STS function. The method of deactivation/activation will be defined locally.

Occupancies of the signalled sections are highly likely to appear to the signalling systems before the reset is carried out.

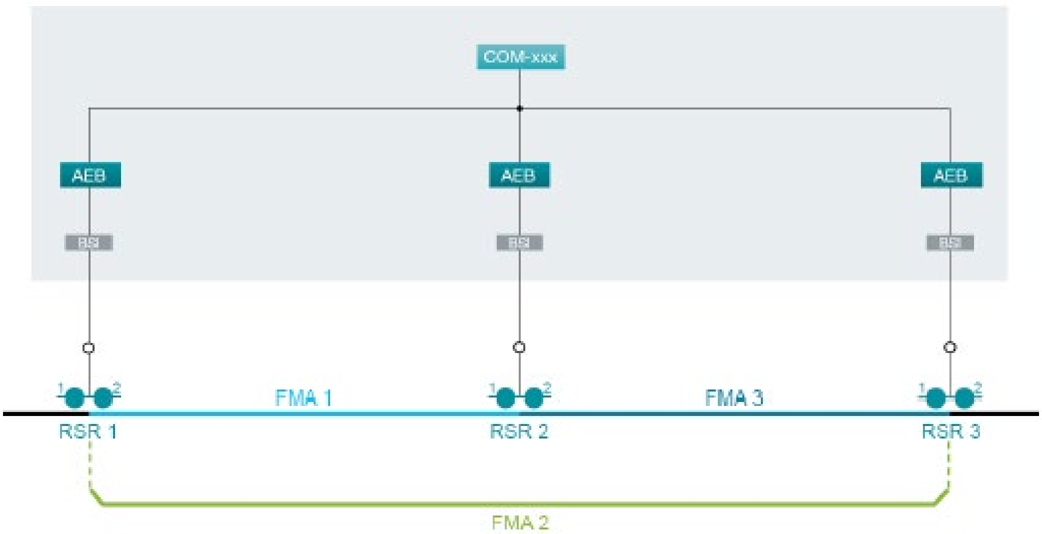

Figure 12 - FMA 2 is an STS covering signalled sections FMA 1 and FMA 3

13. Abbreviations Frauscher Advanced Counter

Abbreviation	Meaning
AEB	Advanced Evaluation Board
ASD	Advanced Service Display
BSI	Overvoltage Protection Unit
CAN	Controller Area Network
CF	Compact Flash
CHC	Counting Head Control
CO-EXB	Configuration Extension Board
COM-AdC	Communication Board for Advanced Counter
COM-WNC	Communication Board (specific implementation of COM-xxx communication board with implemented WNC protocol)
DIP	Dual in-line package
FadC 2.1.x.x-3	Frauscher Advanced Counter with the system number 2.1.x.x-3 (“x” is a free variable parameter for the specific name of the various
FadC	systems)
FDS	Frauscher Diagnostic System
FSC	Frauscher Safe CAN Protocol
IO-EXB	Input/Output Extension Board
PB	Testing plate
PSC	Power Supply with Crowbar
RSR123	Wheel sensor type RSR123
Sys	Sensor system of a wheel sensor
STS	Supervisor Track Section
Reset/pre-Reset	Reset inputs
Fault	An error that can be rectified with a configured Reset procedure, as long the FAdC is/was ready for operation.
Counting head	In functional terms, a counting head consists of a wheel sensor, a BSI and an AEB

END

Includes:	EBI Track 200 Audio Frequency Track Circuit
Excludes:	All other Track Circuits

General

UNDER NO CIRCUMSTANCES should the TX and RX tuning units of one-track circuit be disconnected from the rails at the same time as this can allow unwanted power to pass between the adjacent track circuits resulting in a possible wrong side failure of one of the abutting track circuits.

If an RX or TX is disconnected from its tuning unit, the terminals on that tuning unit to which the 2-core cable was attached should be short circuited, (i.e. terminals 1&2 for an RX or low power TX, terminals 4&5 for a standard power TX) this corrects the tuned zone readings.

A double rail EBI Track 200 track circuit should never be reconfigured as a single rail track circuit.

Before the removal of a Track relay, fed by an analogue RX, the RX should have its power removed to prevent the RX output stage becoming damaged.

The gain or sensitivity should not be increased or decreased where the clear track current (across the 1Ω resistor) has changed by more than 10% without consulting your Supervisor.

Any adjustment should only be to obtain the correct drop shunt, for that track circuit.

Tuned zones should be kept clear of all metallic objects including new or scrap lengths of rail for a distance of at least 1.25m (4ft). The tail cables from the TU to

the rails form part of the tuned circuit, because of this they should wherever possible be bound together, not allowed to form loops and not be run in parallel with the running rails. Failure to observe these items can result in the effectiveness of the tuned area being altered i.e. low or below specification readings.

1. EBI Track 200 Audio Track Circuit:

1.1 EBI Track 200 Layout Configurations

EBI Track 200 track circuits can be used in a number of configurations:

- Single rail configuration using ETUs or TCUs.
- Double rail configuration using TUs for jointless or ETU for jointed track circuits.

- Both single rail and double rail configurations can have multiple Receivers/Track Relays.

Low Power Configurations – Double Rail (ETU & TU)

For track circuits of between 50m (20m where ETUs are used) and 250m in length the EBI Track 200 is configured in a Low Power mode by connecting the TX to terminals 1 and 2 of the tuning unit.

Low Power Configurations - Single Rail

The ETU and SPETU can be used in low power or low power plus modes for tracks between 20m and 250m. Low power is configured by connecting the TX to terminals 1 and 2 of the ETU/SPETU.

Low power plus is configured by connecting the TX to terminals 2 and 5 and providing a strap between terminals 1 and 4of the ETU/SPETU.

Low power plus provides approximately an additional 5% launch voltage over low power tracks for use where single rail tracks are used through S&C.

Additionally, a single rail configuration can be used utilising TCUs which are inherently low power.

1.2 Power Supplies and Fusing

EBI Track 200 can utilise different types of 24VDC power supplies from Bombardier or other suppliers.

An Anti-surge fuse of the type - “Fuse cartridge 3A Anti-surge for PSU AC input, (Cooper Bussmann MDA-3-R Series, ¼” x 1¼”)’. (086/043768)” should be used for both the 110VAC to the Power supply and 24VDC to the Tx/Rx equipment etc.

Relaxation of this requirement is permitted in accordance with the EBI Track 200 Standard NR/L2/SIG/11761.

1.3 SPETU Surge Protection and Fusing

The Surge Protected End Termination Unit is an ETU fitted with surge protection (GDT) and replaceable fuses for use in single rail applications, where protection is required to prevent damage to internal components from traction short circuits.

All applications of the SPETU on Network Rail infrastructure should use the Littelfuse 10Amp 600VAC fuse (KLK D 010, 086/043730). Some MOD states of the SPETU are factory fitted with 5A fuses. These should be replaced by the 10A fuse.

In the event of a SPETU fuse failure; both fuses should be replaced.

In addition, where the GDT is a separate Line Replaceable Unit in later SPETU builds, it should also be replaced by a 145VDC GDT (086/047392) as a precaution against the GDT being stressed and damaged during the original fuse blow event.

Early versions of the SPETU have been delivered with a 95VDC GDT. If the SPETU is reliable there is no need to change the GDT.

However, if the SPETU fuses fail or there is an opportunity to change the GDT, it should be replaced with the 145VDC version (086/047392).

1.4 Test Equipment

A frequency selective meter (FSM), or TI21 Test Meter (TTM), set to the frequency of the track circuit under test should be used for voltage measurements.

It is not acceptable to test EBI Track 200 without an FSM/TTM.

A rail current measuring device such as a Rocoil or Lemflex, used in conjunction with the TTM can be used to measure the TI current in the rail to locate a section of the track bed causing loss of TI power at the Receiver end.

Sleeper testing – The integrity of the Pads and Nylons can be tested using the Bombardier SIT.

1.5 Centre Fed and Cut Section Track Circuits

Each half of a centre fed track circuit or each cut section operates as an independent track circuit and should be tested as such and record cards kept for each part.

1.6 Impedance Bond Tuning

Any impedance bonds within the track circuit should be tuned with the correct resonating capacitor across the auxiliary coil or in the case of B3 3000 and B3 500 bonds (which have no auxiliary coil) the correct tuning module.

Each removable tuning capacitor / module is labelled with the style of bond it should be fitted to; where it is not removable this information appears on the bond itself.

If the earlier PCB type of tuner board (e.g. Howells or WH3 type) is used the correct links should be cut depending on the track circuit frequency.

1.7 Rail-to-Rail Voltage

With the track circuit not shunted by a train or train shunt the rail-to-rail voltage should fall approximately linearly from the TX to the RX end.

In exceptional circumstances (and with permission of the S&T Maintenance Engineer) it may be raised by intermediate tuning capacitors.

1.8 Rail Current

The EBI Track 200 rail current reading gives a more useful reading, than rail voltages, and should be virtually constant throughout the Track Circuit length. It should also be of similar values in both rails.

The Clear Track Current should be within the range defined in Appendix D Table 2.

If the Clear Track Current is outside these values, then the track condition should be investigated to determine the cause of the non-conforming readings.

The Supervisor may advise a higher drop shunt to improve reliability if the track records indicate this is appropriate.

Where impedance bonds, or intermediate tuning capacitors (Bucking Capacitors) have been fitted the current value will have a marked change.

Significant changes in track current indicate leakage faults between the rails which should be investigated and rectified.

It should be noted that PAN8 and Bullhead rail will inherently lose current because of the lack of pads and nylons.

1.9 Tuned Zone Ratios (Pole/Zero Ratios)

Pole – Track under test
Zero – Adjacent/abutting track

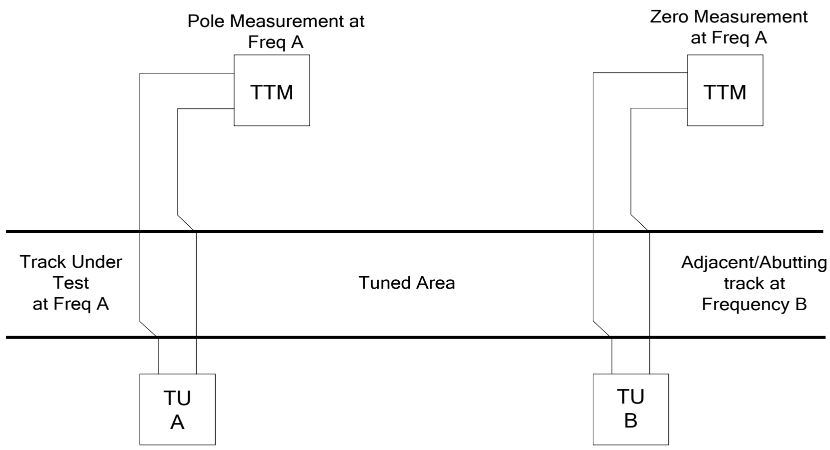

Figure 1 - Tuned Zone Ratios

The Pole voltage is the voltage across the rails at the TU of the track under test (TU A in drawing) at that track's frequency (Frequency A in drawing).

For the purpose of the test this TU can be called the 'Pole TU'.

The zero voltage is measured across the companion tuning unit's (TU B in the drawing) rail terminals at the track under test frequency (Frequency A in the drawing).

For the purpose of the test this TU can be called the 'Zero TU'.

Important points to note are:

- The pole/zero measurement will give no information about the quality of the pole.

  The pole is the property in the Tuning Unit which determines how much signal current is sent down the track to the RX at the other end.

- The pole/zero measurement will give a good measurement of the quality of the zero.

  The zero determines how much unwanted signal flows into the adjacent track.

- The quality of the zero is determined by the impedances caused by:

  - The components within the TU.
  - The tightness of the track and TU connections
  - The layout of the track cables.
  - The equipment (TX/RX) connected to the zero TU.

From the above statements, the following conclusions can be reached:

- Pole/zero ratios are a good method of monitoring the quality of the TU connections and track cable layout.

  As such, they provide evidence that good installation practice has been followed.

- If Pole/zero ratios are measured with an active TX connected to the zero TU, then the ratio will be degraded.

1.10 Mechanical and Electrical Connections

Good quality mechanical and electrical connections are important to obtain reliable operation of the EBI Track 200 equipment.

These connections should be made and maintained in accordance with the torque requirements defined in NR/SMS/PartZ/Z03.

The Advance Plate to Impedance Bond centre tap connection should use the spreader plates and associated installation procedure.

Existing installations should be changed to the updated process if the opportunity arises.

1.11 Spare/Scrap Rail Laid in the 4ft

Placing spare/scrap rail in the 4ft should not affect the operation of the track circuit.

Additionally, the constraint for not placing rail in the 4ft through a Tuned Zone should be complied with.

However, it is recognised that it is not always possible to comply with the TZ constraint. In which case there are some actions which will mitigate against unreliable operation or TC failure.

1.12 TU/ETU/SPETU hoods (Acoustic Jackets)

These should be fitted in areas close to residential property where noise might cause a nuisance.

1.13 Intermediate Tuning Capacitors

These are used to increase the gain at intermediate positions in the track circuit to overcome low ballast resistance caused by poor formation and/or rail fastenings.

They shall not be fitted without permission from the S&TME.

They also require individually specified drop shunt testing along the length of the track circuit at increased frequency

1.14 Receiver Current – Analogue

RX current is measured at the 1Ω resistor on the RX input terminals with a FSM or TTM.

This is the actual physical quantity that the track circuit uses to determine the presence of a train and so is a direct measure of the overall health of the circuit.

Clear track RX current is approximately twice the threshold at which the track relay drops (the threshold is determined by the gain strapping and can be found by reference to Appendix D Table 6.

1.15 Receiver Current – Digital

RX current is measured at the 1Ω resistor on the RX input terminals (TP1 and IPC) with an FSM or TTM or by using the display.

This is the actual physical quantity that the track circuit uses to determine the presence of a train and so is a direct measure of the overall health of the circuit.

Clear track RX current is approximately twice the threshold at which the track relay drops (the threshold is determined during the setup procedure in Appendix E.

1.16 Receiver Current – General

The RX current is affected by:

- The quality of the TX pole.
- The quality of the RX pole.
- Ballast resistance.
- Feed through from adjacent track circuits of the same frequency.

From the previous statements, the following conclusions can be reached:

- RX current is an excellent overall measure of the stability of the track circuit. Significant changes in current are due to either degradation in the TUs, or changes in the leakage current between the rails. e.g. impedance bonds, rail bonds, check rails etc.

A significant change should be determined by which is the greater of:

- a change of ±20% in the track current
- or a change of ±10mA in the track current.

These factors require investigation if fault-free operation is to be maintained’

1.17 Using the Digital Rx Mating Connector with adaptor for or Fork Terminals.

The Digital Rx Mating Connector is used to present the screw terminal connections for wiring purposes, using fork crimps, when an Analogue Rx is converted to a Digital Rx.

If the wrong wiring connections are made to the Receiver, the TC will become unreliable because the Clear Track Current in to the Receiver will be seen to be incorrect.

1.18 Tuned Zones

Pole/zero ratios are useful in monitoring installation standards.RX current is the most effective measure of track circuit performance and stability since it measures the effectiveness of the pole circuit and signal leakage effects.

1.19 Tuned Zones on Steel Sleepers

The following Special instructions for tuned zone installations should be followed:

- The tuned zone is 22m ± 0.5m
- All the sleepers within the zone, and for 3 bays either side, are of a Network Rail accepted steel type
- The tuned zone is not part of a TI 21/Aster hybrid interface
- Single Rail Application
- RX current can be affected by the quality of the rail connections, bonded out joints, IRJ’s and S&C insulations (sole plates, stretcher bars etc).

FAULT FINDING GUIDELINES

2. General

Before starting work, all track connections should be checked for tightness as described in NR/SMS/PartC/TC16 (Track Circuit: EBI Track 200)

The Bombardier Hints and Tips document ‘EBI Track 200 Track Circuit: Aid for Maintenance & Fault Finding’ can be also referenced.

The health of a track circuit can be determined by the voltage measured across the 1Ω resistor.

Any changes to the TX output level, the TX or RX ETU, TU or TCU the track bed or associated tuned zone equipment will affect the receiver input current.

The track relay voltage will indicate the correct functioning of the RX and that the relay coil is not damaged. If the relay coil voltage is low, it will indicate a failing RX unit.

The relay end rail voltage is a measure of the energisation level of the track circuit.

It will change inversely proportional to the drop shunt value and will be affected by the same factors.

A low rail voltage will indicate a faulty TU/ETU/TCU or a faulty connection at any part of the track.

If two adjacent track circuits fail simultaneously, the fault is most likely where the two tracks adjoin. Check the tuning units and associated connections and other shared equipment like the PSU.

For centre fed track circuits any problem within 30 metres of the centre feed will affect both sections.

If low ballast resistance is suspected see if the problem can be localised. On concrete sleepered track Check the pads and clip insulations.

On timber sleepered track Check for poor ballast drainage and P8 type rail fastenings.

If the problem can be isolated, spot replacement of rail insulations or replacement of P8 fastenings with P14 should be considered. (if you are in doubt about the type of fastenings, ask your SM(S)

Checking obtained readings against those on the Record Card and investigating those that have significantly changed can reveal the source of the fault.

Using an FSM/TTM the measurement of the rail-to-rail voltage at regular intervals from TX to RX should show a gradual decrease of the voltage.

The rail current reading gives a more valued reading than track voltage and typical current readings are:

- Normal power = 1.0 - 1.5 Amp
- Low power = 0.5 - 0.75 Amp
- Low power plus = 0.55 - 0.8 Amp

Within a tuned zone

- Each RX =5 Amp, each TX = 10 amp (5 if low power or low power plus) per frequency

3. Feed (Transmitter) End

3.1 Measure the PSU output voltage and current. If the readings are within the specified limits Measure the TX output using TTM. If the voltage is outside its specified limits

3.2 Check the PSU input tapings are set to P5 and P115. If not, adjust the tapping settings.

3.3 Measure the voltage on the 110V signalling supply to the PSU. If the supply is over 115VAC, adjust the PSU output tapings to give between 25V and 27V DC.

Otherwise, adjust the PSU output tapings to give ideally 24V - 26V DC.

If the current drawn by the TX is outside its specified limits, the PSU, TX or TU/ETU/TCU shall be replaced.

3.4 Measure the AC Ripple on the 24V DC from the PSU.

Values exceeding 1V shall be investigated to eliminate the cause or the PSU replaced.

3.5 Check that the TX is emitting a regular warbling noise. If the tone is fixed rather than warbling, this indicates that the unit is not modulating.

In this case, first Check that the mod pin is not connected to B24 or N24. If it is not warbling, or the sound is unusual or irregular, remove the 24V supply fuse and replace it after a couple of minutes.

If this activates the unit, it shall be replaced as it could fail again. If the warbling does not start, also replace the TX.

3.6 Measure the rail voltage between the TX rail connections, if they are outside the specified limits check all the associated TU/ETU/TCU connections (including equipment in the location housing) and then test the units themselves and replace as necessary.

3.7 If the TX is at a tuned zone calculate the tuned zone ratio (Appendix B). If a low ratio is found Check all associated TU/ETU/TCU connections (including equipment in the location housing) and then Test the units themselves and replace as necessary. If the fault has cleared move to 3.9.

3.8 Place a short circuit between terminals T1 and T2 on the adjoining TU/ETU (this will cause the track circuit to show occupied) and Measure the rail voltage at the TX.

It should not have altered from the previous reading in 3.6

If it is not the same, check all the associated TU/ETU/TCU connections (including equipment in the location housing) and then Test the units themselves and replace as necessary.

Remove the short circuit and re-calculate the tuned zone ratio (Appendix B).

3.9 Measure the rail voltage at the TX.

3.10 Connect a shunt set at 1Ω across the rails at the TU/ETU connections and measure the rail voltage again. The rail voltage should decrease by 50%.

3.11 Remove the shunt and the voltage should rise immediately to the first reading. If this is the case then it can be assumed that all the TX equipment is working correctly.

Impedance Bonds (Where Fitted)

Before checking the impedance bond(s) the TX equipment shall first be proved to be operating correctly.

3.12 Check that no corrosion, dirt oil or water is present in the terminal box and/or connection points.

3.13 Measure the voltage across the auxiliary coil or tuning module (NOT applicable to B3 3000 and B3 500 bonds), check it is in the correct ratio with the rail-to-rail voltage (Appendix C).

If it is correct the bond should be operating correctly, if it is incorrect proceed with the next step.

3.14 Check the tuning capacitor/module is correct for the style of bond and the track circuit frequency. Apply a short circuit across the tuning capacitor/module and

3.15 Measure the voltage. Remove the short circuit and Check the voltage rises.

If there is not a dramatic rise in voltage replace the tuning capacitor/module.

If this still does not improve matters consider replacing the bond.

Near ETU units this tuning capacitor/module test might not work.

For Intermediate Bonds Only

3.16 Place the Rocoil over the rail 1 metre before the Bond (TX side) and note the reading on the TTM (= amps, I1).

3.17 Repeat the measurement 1 metre from the bond on the RX side (I2)

3.18 Subtract I2 from I1 thus obtaining the current through the bond at the EBI Track 200 frequency.

3.19 Measure the rail to rail voltage (V) across the impedance bond.

3.20 Divide the voltage (V) by the current calculated from 2.3.6 thus giving the impedance (Z), Z= V / (I1-I2).

This value should be greater than 8Ω.

If less than 8Ω, check for traction imbalance before remedial action is taken with the impedance bond. (The Manufacturers specification is 12Ω when measured at the Capacitor frequency)

It is possible to verify the Impedance Bond is within the manufacturers specification by measuring the Bond inductance without the tuning capacitor connected.

The value should be between 27.8 to 28.2 µHenries.

The value between the rail connections and the centre tap will be half these values.

4. Relay (Receiver) End

4.1 Observe the track relay. If energised, Check the line circuits as the fault is between the relay and the signallers ‘Occupied’ indication.

4.2 Measure the DC voltage across the track relay coils.

- 40V to 75V DC for the analogue RX
- 40V to 44V DC for the digital RX MOD 1 & 2
- 48V to 52V DC for the digital RX MOD 3

If it is within the specified limits remove the receiver 24V supply fuse and replace the relay. Replace the supply fuse on completion.

4.3 Measure the RX 24V DC supply voltage.

- 22.5V to 30.5V DC

4.4 Measure the AC Ripple on the 24V DC from the PSU. It should not exceed 1V. Values above this level should be investigated to eliminate the cause or the PSU replaced.

If the voltages are within the specified limits go to move to Step 4.7.

4.5 Measure using a FSM/TTM the rail voltage at the RX rail connections. If they are within the specified limits go to Step 4.6.

If they are not attention should be given to a track circuit examination and testing at the TX end.

Low rail volts could be due to ballast or other track equipment, as well as a fault at the TX end of the track

4.6 Calculate the tuned zone ratio (Appendix B). If this ratio is lower than the specified limits test all the TU/ETUs and their connections replacing where necessary. If the ratio is within the specified limits and the fault still remains, replace the adjoining TU.

4.7 Measure the Receiver input voltage, using a TTM, and the frequency, using a multimeter, across the surge arrestors.

4.8 At the Transmitter place a shorting link on the B24 and mod transmitter terminals, and note the values at the RX end.

This causes the TX to transmit the upper sideband frequency (USB)

4.9 At the Transmitter remove the B24 – Mod short strap and place the shorting link on the N24 and mod transmitter terminals, and note the values at the RX end.

This causes the TX to transmit the lower sidebands frequency (LSB)

4.10 The USB and LSB frequencies recorded should be within ±4Hz of the figures in Appendix G. If not, then the Transmitter is off frequency and should be replaced.

If the voltages noted at the RX end give a sideband imbalance ratio greater than 1.6:1 for TU, ETU & SPETU or 1.8:1 for TCU ratio, then at least one of the TUs/ETUs/TCUs for that track circuit are out of specification.

If so, then repeat this test at the TX TU/ETU/TCU to determine whether the RX TU/ETU/TCU is at fault or the TX TU/ETU/TCU.

4.11 Remove shorting strap on completion of the steps 4.8 and 4.9.

4.12 Measure the voltage and current supplied by the PSU. If they are not within the specified limits check the PSU tapping and/or replace the PSU.

4.13 Measure the voltage across the 1Ω resistor; compare this reading against the Record Card.

If the obtained reading is not within 10% of the Commissioning reading or last Set-up reading on the Record Card, the reason for the discrepancy should be investigated.

Appendix D Table D2 can be also consulted if the track has a history of poor performance.

If adjustment is required, the initial setting for an analogue RX should be selected from Appendix D table 5 using the voltage across the 1Ω resistor, followed by a drop shunt test. For digital RX, an auto-set routine should be performed.

The gain should only be altered to obtain the correct drop shunt.

5. Interference Test

To check the traction interference levels on the track the following test are carried out on T1-T2 terminals of the ETU/TU or the TCU surge arrestors.

<u>For traction areas only:</u>

5.1 Remove the B24 fuse to the TX and Check the correct track relay drops.

5.2 Measure the voltage across the track using a TTM set to AC 200mV range.

5.3 Measure the frequency across the track using a multimeter.

Record both the voltage and frequency readings.

Readings greater than 100mV are un-acceptable, the track circuit should be investigated and your SM(S) informed.

If there is a problem, this test can be repeated with the Traction supply OFF as this can help to identify the source of the interference.

5.4 If all the readings appear to be correct but the track circuit remains failed then recheck all items above and check there are no problems arising from Spare / Scrap rail laid in the 4ft. See Steps 6.1 and 6.2.

6. Spare/Scrap Rail Laid in the 4ft

Placing spare/scrap rail in the 4ft should not affect the operation of the TC.

Additionally, the constraint for not placing rail in the 4ft through a Tuned Zone should be complied with.

However, it is recognised that it is not always possible to comply with the TZ constraint.

In which case there are some actions which will mitigate against unreliable operation or TC failure.

6.1 Measure the current flowing in the rail laid in the 4ft using a Rocoil. This should be Zero.

If current is found to be flowing in the rail, then there is likely to be physical contact between the running rails and the spare rail. This should be rectified.

6.2 Check the TZR before and after the rail is laid in the 4ft.

If the change in TZR is less than 10%, there should not be any further problems. This check should be repeated when the rail is removed from the 4ft.

7. Using the Digital Rx Mating Connector with adaptor for or Fork Terminals.

The Digital Rx Mating Connector is used to present the screw terminal connections for wiring purposes, using fork crimps, when an Analogue Rx is converted to a Digital Rx.

If the wrong wiring connections are made to the Receiver, the TC will become unreliable because the Clear Track Current in to the Receiver will be seen to be incorrect.

7.1 Check the wiring for the rail connections which should be connected to IP1 and IPC (See figure).

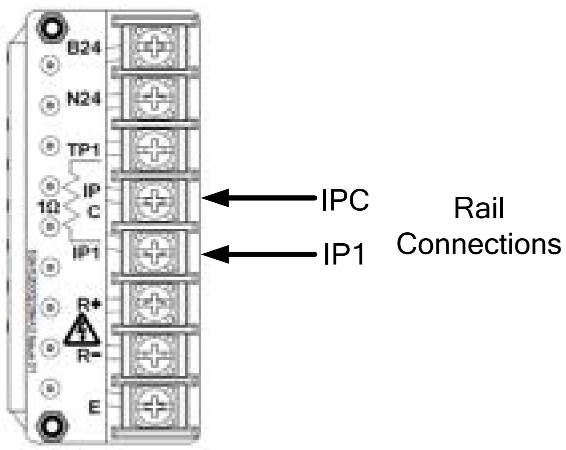

Figure 2 – Rail Connections

In later versions of the Mating Connector with adaptor for Fork Terminals, the screw in TP1 is removed

7.2 Check the Average Current is within 10% of the 1Ω Value from the Record Card.

If the Average Current is approximately 50% of the 1Ω Value from the Record Card, check that the rail connections are not erroneously connected to IP1 and TP1.

If the Average Current is approximately 1% of the 1Ω Value from the Record Card, check that the rail connections are not erroneously connected to IPC and TP1.

APPENDIX A - Typical Rail-to-Rail Voltages (Vp)

Operation	Track Length (m)	TX End Volts Freq ACEG	RX End Volts Freq ACEG
Low Power	20	0.5V – 0.7V	0.6V – 0.7V
	50	0.6V - 0.7V	0.6V – 0.7V
	150	0.9V - 1.1V	0.4V – 0.7V
	250	1.1V - 1.3V	0.3V – 0.5V
Low Power Plus	50	0.6V - 0.8V	0.6V – 0.8V
	150	1.1V – 1.5V	0.4V – 0.7V
	200	1.2V – 1.5V	0.4V – 0.7V
	250	1.3V – 1.5V	0.3V – 0.6V
Normal Power	200	4.5V – 5.3V	1.1V – 2.6V
	400	4.2V – 6.0V	0.5V – 1.0V
	600	4.2V – 6.1V	0.3V – 1.0V
	900	4.2V – 6.2V	0.2V – 0.7V
	1100	4.2V – 6.2V	0.1V – 0.5V

Table 1 – Rail Voltage's for Frequencies A C E and G

Operation	Track Length (m)	TX End Volts Freq BDFH	RX End Volts Freq BDFH
Low Power	20	0.9V – 1.1V	0.9V – 1.1V
	50	1.0V – 1.2V	0.8V – 1.1V
	150	1.4V - 1.7V	0.6V – 0.8V
	250	1.6V – 2.0V	0.5V – 0.6V
Low Power Plus	50	1.0V – 1.3V	0.8V – 1.2V
	150	1.7V – 2.2V	0.6V – 0.8V
	200	1.8V – 2.2V	0.6V – 0.9V
	250	1.9V – 2.3V	0.5V – 0.7V
Normal Power	200	5.8V – 7.1V	1.9V – 2.8V
	400	6.1V – 7.5V	0.9V – 1.6V
	600	6.0V – 7.6V	0.6V – 1.1V
	900	6.0V – 7.7V	0.3V – 0.7V
	1100	6.0V – 7.7V	0.2V – 0.6V

Table 2 - Rail Voltage's for Frequencies B D F and H

APPENDIX B - Tuned Zone Ratios

These ratios are the absolute MINIMUM values acceptable. The table below takes into account the latest installation standards and cable types.

If the Tuned Zone Ratio is not achievable, check the quality of the installation.

Pole	Frequency	Zero	Frequency	Ratio
Tx	ACG	Rx	BDH	12:1
Tx	ACG	Tx	BDH	11:1
Rx	ACG	Tx	BDH	12:1
Rx	ACG	Rx	BDH	12:1
Tx	BDFG	Rx	ACEG	18:1
Tx	BDFG	Tx	ACEG	15:1
Rx	BDFG	Tx	ACEG	18:1
Rx	BDFG	Rx	ACEG	18:1
Tx	E	Rx	F	9:1
Tx	E	Tx	F	8:1
Rx	E	Tx	F	9:1
Rx	E	Rx	F	9:1

Table 3 – Tuned Zone Ratios

APPENDIX C - Impedance Bond Voltage Ratios

Impedance Bond Style	Voltage Ratio
DE	40:1
MR	56:1
P3	45:1
S	56:1
WH3	56:1
B3 500	Not applicable
B3 3000	Not applicable

Table 4 - Impedance Bond Voltage Ratios

APPENDIX D - Analogue RX

Gain	Drop Across 1Ω Resistor (mV)	Input 1	Input 2 Strap (Note D)	Strap 1	Strap 2
1	390	1H	1L		
2	195	3L	1L	1H-3H	
3	134	3H	3L		
4	98	1H	3L	1L-3H	
5	78	3L	9L	1H-9H	1L-3H
6	65	3L	9L	3H-9H	
7	56	3L	9L	1H-3H	1L-9H
8	50	1L	9L	1H-9H	
9	45	9H	9L		
10	39	1H	9L	1L-9H	
11	35.4	3H	9L	1L-3L	1H-9H
12	32.4	3H	9L	3L-9H	
13	30	1H	9L	1L-3H	3L-9H

Table 5 - Receiver Gain Connections

The voltage measured across the 1Ω resistor is the clear track current.

A Strap 1 and Strap 2 refer to wire positions not labels.

B When no straps are listed in the table, they are not required.

C Input 1 and Input 2 can be either of the pair of cores from the tuner unit.

D Input 2 is always taken to the bottom of the 1Ω resistor; its associated strap is always taken from the top of the 1Ω resistor to the terminal shown.

E The drop across the 1Ω resistor is used with this table to set the initial gain, the final setting is made by placing a shunt box across the rails at the RX tuning unit and adjusting the tapping to obtain an optimum shunt value.

	Clear Track Receiver Current (mA)			
Track Length	**Normal Power**		**Low Power or Low Power Plus**	
(m)	**Min**	**Max**	**Min**	**Max**
20 – 100	-	-	43	106
100 – 150	-	-	38	90
150 – 200	-	-	33	76
200 – 250	130	251	28	66
250 – 300	110	213	-	-
300 – 400	81	184	-	-
400 – 500	62	143	-	-
500 – 600	48	116	-	-
600 – 700	38	98	-	-
700 – 800	31	84	-	-
800 – 900	25	74	-	-
900 – 1000	24	66	-	-
1000 – 1100	24	60	-	-

Table 6 - Expected Range of Track Currents against Track Circuit Lengths

This table provides a reference for Operational tracks to give guidance on the expected Clear Track Receiver Current depending on the track length.

NOTE: *This table is not required for setting up the track.*

Where Transmitter circuits use LMUs, the line losses become insignificant and therefore the table also applies.

However, where long TX to TU/ETU cables are in use without LMUs, then the table does not apply due to the losses in the cable.

Typical Gain Setting figures for single rail using TCUs

The Table shows the initial sensitivity setting at the Receiver for the combination of track circuit lengths and combined rail-to-TCU cable lengths. The combined rail-to-TCU cable length is the length of the transmitter TCU-to-rail feed cable plus the length of the receiver TCU-to rail feed cable.

		Total TX + RX Rail-to-TCU Cable Length			
		0 to 70m	**70 to 130m**	**130 to 200m**	**200-350m**
Track	**0 to 70m**	60mA	55mA	50mA	35mA
	70 to 130m	75mA	60mA	55mA	35mA
	130 to 200m	90mA	65mA	55mA	35mA

Table 7 - Digital Rx

		Total TX + RX Rail-to-TCU Cable Length			
		0 to 70m	**70 to 130m**	**130 to 200m**	**200-350m**
Track	**0 to 70m**	6 – 7	7	8	11
	70 to 130m	5 – 6	6 - 7	7 - 8	11 – 12
	130 to 200m	4 - 5	6	7	12

Table 8 - Analogue Rx

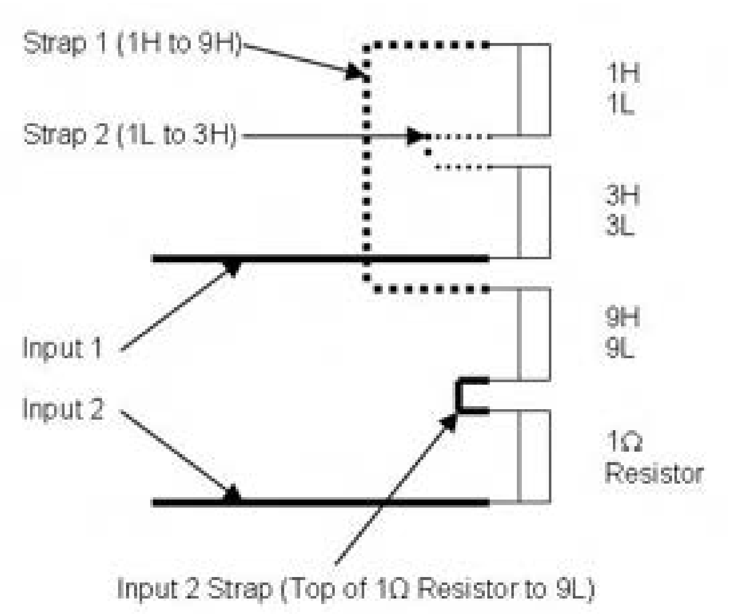

Figure 3 – An Example of the Strapping of an Analogue Receiver

Figure 3 shows the connections and strapping require to set the receiver gain to setting 5

- Input 1 from TU/ETU to 3L
- Input 2 from TU/ETU to bottom of 1Ω resistor
- Input 2 strap from top of 1Ω resistor to 9L
- Strap 1 from 1H to 9H
- Strap 2 from 1L to 3H

APPENDIX E - DIGITAL RX Set up procedure for the Digital Receiver

This procedure shall be completed regardless of whether the unit has been previously used or not.

If safe track access is possible then this process. If not, then the follow the set-up procedure shown in Appendix G can be used.

1. Power up the Receiver. The display will respond with ‘KEY?’. Fit the correct frequency key for the track circuit under test.

2. The display will echo back the frequency in the format, for example ‘200A’ for frequency A, and then display ‘NewK’.

A previously set up Receiver will display the relay state (‘PICK’ or ‘drop’).

3. Confirm that RX has a supply voltage within the range 24V to 26V.

<u>On the Receiver</u>

Press OK then ‘NEXT’ until ‘Vpsu’

Press OK this displays the PSU Voltage

Note this Value

4. Confirm the track circuit has a Sideband imbalance ratio less than:

- 1.6:1 for TU/ETU/SPETU
- 1.8:1 for TCU

On the Receiver

Press OK then 'NEXT' until 'INOW'

Note this Value

Press OK then Next Until 'USB'

Press OK and note the value.

Press 'BACK' then 'NEXT' until 'LSB'

Press OK and note the value.

Calculate and record sideband imbalance by dividing the larger value by the smaller value.

Note this Value

NOTE: *If the sideband imbalance exceeds the ratio values above, the track circuit should be investigated to ascertain the cause of the imbalance. Carry out steps 4.7 to 4.11.*

5. Confirm Average current seen by the RX.

On the Receiver

Press OK then 'NEXT' until 'INOW'

Press OK then Next Until 'AV'

Press OK this displays the average current seen by the Unit.

Note this Value

For existing installations:

6. Using the Average Current value from the test above, confirm that it is the same as that recorded on the track Record Card or within 10% of that value.

If the clear track current is more than 10% below the expected level, or is pulsing this indicates that the track circuit is losing current and is not a receiver problem.

In this case the cause of the current loss should be determined and rectified otherwise the safety margin of the circuit can be eroded.

<u>For new digital receiver Installations (Projects or Maintenance replacement)</u>

7. Refer to Table 6 (Typical Track Currents against Track Circuit Lengths) and confirm that the value noted in 5A above is within 20% of the expected value from the table.

8. Determine the ratio between the TX end and RX end rail currents as described below.

9. Using a TI21 Test Meter (TTM) and a Rocoil rail current Transducer (or functional equivalent);

   Measure the signal current at the meter points shown in figure 4.

   Compare I1a with I1b and discard the lower value.

   Compare I2a with I2b and discard the higher value.

   Obtain the ratio IRail by dividing the RX end current (lowest I2) by the TX end value (highest I1).

   Record this value on the record card.

   NOTE: *In points tracks, where multiple receivers are used, then a current measurement must be taken adjacent to each receiver and the values added together to obtain the I2 value for use in Tables 9 to 14.*

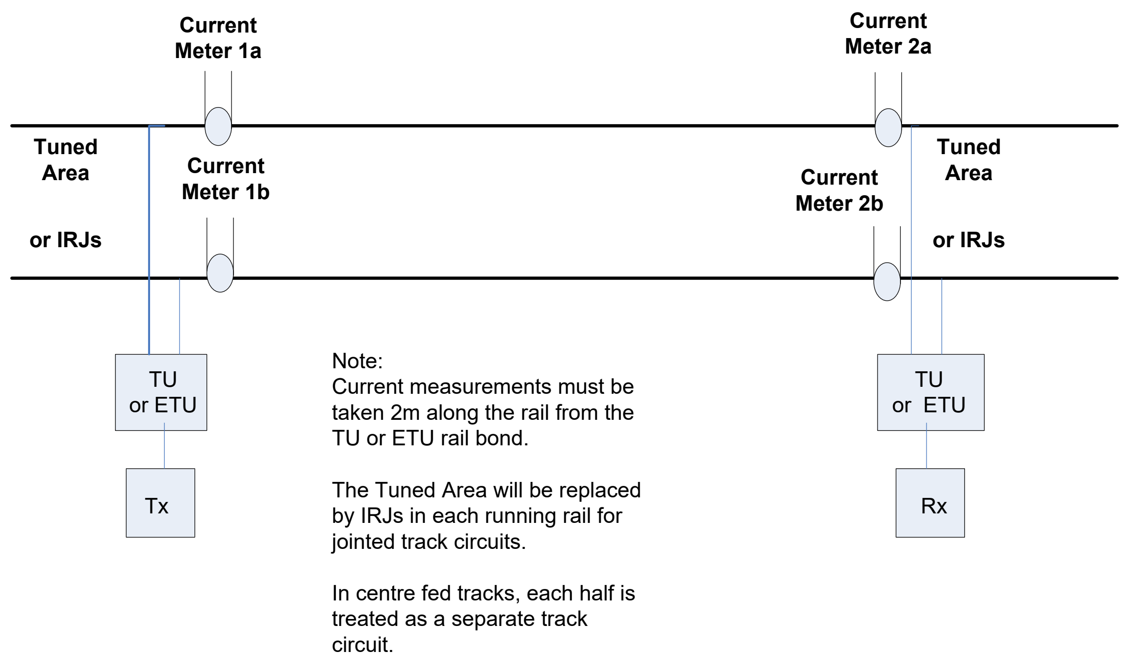

Figure 4 - Measurement Points for IRail Ratio Determination

10. Determine the value of ballast impedance by inspection of the Tables 9 to 14 (check that the table appropriate to the frequency and low power / normal power setting of the track circuit is used).

    Record this value on the record card.

Determination of Ballast Impedance from Irail ratio % for Various Track Lengths

175-224	81	87	90	92	93	95	96	97	98	100
225-250	76	83	87	90	91	93	95	97	97	100

Table 14 - Low Power Frequencies D and H

11. Determine the set-up shunt to be used by inspection of Tables 15 and 16 (use appropriate Low Power / Normal Power table).

If the set-up shunt is given as ‘Special’ this indicates that the ballast is in a very poor condition.

As an interim measure, until the ballast can be rectified, track circuits should be set up at 3Ω.

Affected track circuits should be monitored weekly for changes in Rx clear track current (Inow on the Rx display).

If Inow changes by more than 10% from the value at set up, then the track shal be re-set. Record the set-up shunt value on the record card.

If the ballast measurement of a track circuit in special measures does not return to normal levels and can be shown to be stable over several months, then a case can be made for reducing the set-up shunt.

NOTE: *If the IRail ratio measurement requires the use of higher shunt values, and the track is not very wet, then this indicates that there is severe loss of current down the track which should be investigated and corrected.*

Determination of Set Up Shunt from Ballast Impedance for Various Track Lengths

Track Length (m)	**Ballast Impedance Ωkm**							
	2	**3**	**4**	**5**	**6**	**8**	**10**	**15 and above**
200-249	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0
250-349	1.2	1.2	1.0	1.0	1.0	1.0	1.0	1.0
350-449	1.2	1.2	1.2	1.0	1.0	1.0	1.0	1.0
450-549	1.4	1.2	1.2	1.2	1.0	1.0	1.0	1.0
550-649	1.6	1.4	1.2	1.2	1.2	1.0	1.0	1.0
650-749	2.0	1.4	1.2	1.2	1.2	1.0	1.0	1.0
750-849	2.4	1.6	1.4	1.2	1.2	1.2	1.0	1.0
850-949	Special	1.8	1.4	1.4	1.2	1.2	1.0	1.0
950-1050	Special	2.2	1.6	1.4	1.2	1.2	1.0	1.0
1050-1100	Special	2.8	1.8	1.6	1.4	1.2	1.2	1.0

Table 15 - Set Up Shunt (Ω) for Normal Power All Frequencies

Track Length (m)	**Ballast Impedance Ωkm**				
	2	**3**	**4**	**5**	**6 and above**
20-74	1.5	1.5	1.5	1.5	1.5
75-124	1.7	1.5	1.5	1.5	1.5
125-174	1.7	1.7	1.7	1.5	1.5
175-250	1.9	1.7	1.7	1.7	1.5

Table 16 - Set Up Shunt (Ω) for Low Power All Frequencies

An example set-up shunt determination:

- Frequency B track circuit, 757m long.
- I1a = 1.012A   I1b = 1.023   Use 1.023A
- I2a = 757mA   I1a = 782mA Use 757mA
- IRail Ratio = 757/1023 = 0.74 = 74%
- Ballast (Table E1.b) = 8Ω
- Set Up Shunt (Table E1.g) = 1.2Ω

12. Connect a shunt box across the rails at the receiver TU or ETU track connections.

    Set the drop shunt to the value determined in step 11.

    Check that clear track current has fallen to less than 80% of the value before the shunt box was connected.

13. Replace the frequency key with the set-up key.

    The display will respond with ‘SET?’

    Press the ‘OK’ button to begin the automatic set-up process

    NOTE: *If the set up key is left in place for more than 1 minute, then the set up function will time out and the threshold will be set to zero.*

14. The condition monitoring display will show the legend ‘WAIT’, followed by ‘PASS’ or ‘FAIL’.

    ‘PASS’ indicates that set-up has been successful, and the new gain settings have been locked into the unit.

    ‘FAIL’ indicates that set-up was unsuccessful because, for example, the wrong frequency key has been used, or the track current is too low.

    In this case, ‘FAIL’ will cycle with the reason for failure shown as a code. (See APPENDIX H)

    The track circuit should be investigated, and faults corrected before set-up is attempted again.

    NOTE: *If the set up fails, then the threshold will be set to zero.*

15. Leaving the Shunt box applied. Replace the set-up key with the frequency key.

16. Check that clear track current is still below 80% of the value without the shunt box connected.

17. Remove the shunt box and check that the current recovers to the value noted in step 4.

    If step 17 is positive then release the shunt push button and confirm that the track relay picks.

18. Connect a shunt box, set to 0.7Ω, across the rails at the transmit end TU / ETU track connections and check that the track circuit drops.

19. Record the threshold level on the track circuit record card and confirm that the clear track current is correctly recorded.

20. Carry out a full test of the track circuit and record all values as required in the track Record Card

This completes the receiver set up.

NOTE: *Where Low Power or Low Power Plus tracks are used, the appropriate 'Low Power' or 'Low Power Plus' labels are required for the TX, RX and TUs / ETUs / SPETUs*

APPENDIX F - An alternative method for setting up the track circuit after a failed Transmitter LMU-TX, LMU-TU or TU/ETU

The SM(S) should risk assess the ability to gain safe site access and the competence of Maintenance staff attending the track circuit equipment and should satisfy themselves that the use of the procedure is appropriate and authorise its use.

A full test should be carried out as soon as practically possible.

Deferral of testing, up to a limit of 48 hours, can be permitted on the basis of safety if this setup procedure is used.

1. Remove the faulty unit and replace with the new one.

2. Note the clear track and threshold current values recorded on the track circuit record card.

3. Check that the threshold value on the receiver (Ith) is the same as that entered on the record card.

   For track circuits with multiple receivers, all thresholds shall be checked.

   If the thresholds have not changed then proceed to Step 9

4. Check that the clear track current is within ±20% of the original value.

   If the clear track current is more than ±20% of the original value proceed to Step 7 unless track access is not available to perform drop shunt testing, in which case proceed to Step 9.

5. Check that all receivers drop with 0.8Ω across their rail connections, and that 0.7Ω at the transmitter rail connections drops all receivers in the track circuit.

If the drop shunt tests fail proceed to Step 9.

6. Fill in the record card. Set up completed. Do not carry out steps 7, 8 or 9

7. Check that all receivers drop with 0.8Ω across their rail connections, and that 0.7Ω at the transmitter rail connections drops all receivers in the track circuit.
If the drop shunt tests fail proceed to step 9.

8. Complete the record card.

The setup has been completed. Do not proceed to step 9.

9. The criteria for using the shortened set up procedure have not been met. A Full Test shall be performed.

A full Set-Up procedure (APPENDIX E) should be carried out as soon as practically possible.

Deferral of Setting Up and Testing, up to a limit of 48 hours, might be permitted on the basis of safety if this setup procedure is used.

This completes the track set up using this process.

NOTE: *Where Low Power or Low Power Plus tracks are used, the appropriate 'Low Power' or 'Low Power Plus' labels are required on the TX, RX and TUs / ETUs / SPETUs*

APPENDIX G - An alternative method for setting up the Receiver after a failed Receiver or failed Set-up Key

The SM(S) should risk assess the ability to gain safe site access and the competence of Maintenance staff attending the track circuit equipment and should satisfy themselves that the use of the procedure is appropriate and authorise its use.

A full test shall be carried out as soon as practically possible.

Deferral of testing, up to a limit of 48 hours, may be permitted on the basis of safety if this setup procedure is used.

This procedure is to be completed regardless of whether the unit has been previously used or not.

1. Power up the Receiver. The display will respond with 'KEY?'.

2. Fit the correct frequency key for the track circuit under test.

The display will echo back the frequency in the format, for example ‘200A’ for frequency A, and then display the relay state (‘PICK’ or ‘drop’) or can display ‘NewK’.

3. Confirm that RX has a supply voltage within the range 24V to 26V

On the Receiver

Press OK then ‘NEXT’ until ‘Vpsu’

Press OK this displays the PSU Voltage

Note this Value

4. Confirm Average current seen by the RX.

On the Receiver

Press OK then ‘NEXT’ until ‘INOW’

Press OK then Next Until ‘AV’

Press OK this displays the average current seen by the Unit.

Note this Value

5. Confirm the track circuit has a Sideband imbalance ratio less than:

- 1.6:1 for TU/ETU/SPETU
- 1.8:1 for TCU

On The Receiver

Press OK then ‘NEXT’ until ‘INOW’

Press OK then Next Until ‘USB’

Press OK and note the value.

Press ‘BACK’ then ‘NEXT’ until ‘LSB’

Press OK and note the value.

Calculate and record sideband imbalance by dividing the larger value by the smaller value.

NOTE: *If the sideband imbalance exceeds the ratio values above, the track circuit should be investigated to ascertain the cause of the imbalance. Carry out steps 4.7 to 4.11.*

6. Using the Average Current value from the test above, confirm that it is the same as that recorded on the track Record Card or within 20% of that value.

If the clear track current is more than 20% outside the required level, or is pulsing this indicates that the track circuit is losing current and is not a receiver problem.

In this case the cause of the current loss should be determined and rectified otherwise the safety margin of the circuit can be eroded.

NOTE: *Items such as Ballast or Equipment degradation and Environmental Conditions (Temperature Extremes, Heavy Rainfall) etc. should all be considered.*

Variations are permitted under exceptional circumstances depending on ballast and environmental conditions.

7. Using the 2mm test lead adaptors, attach a Shunt Box across the IPC and IP1 terminals, or at the equivalent point on the surge arrestor terminals.

Adjust the shunt resistance so that the average track current reads the same as the threshold current value recorded on the test record card.

8. Leaving the Shunt Box in place, remove the frequency key and replace it with the set-up key.

The display will respond with ‘SET?’.

Press the ‘OK’ button to begin the automatic set-up process.

9. The condition monitoring display will show the legend ‘WAIT’, followed by ‘PASS’ or ‘FAIL’.

‘PASS’ indicates that set-up has been successful, and the new gain settings have been locked into the unit.

‘FAIL’ indicates that set-up was unsuccessful because, for example, the wrong frequency key has been used, or the track current is too low.

In this case, ‘FAIL’ will cycle with the reason for failure shown as a code. (See APPENDIX E)

The track circuit should be investigated, and faults corrected before set-up is attempted again.

10. Leaving the Shunt box applied. Remove the Set-up key and replace with the Frequency Key. Confirm that the INOW AV current is the same as the Record Card Ith.

    If not, then the set-up procedure needs to be repeated.

11. If Step 10 is positive then release the shunt push button and confirm that the track relay picks.

12. Check that the clear track current is within ±20% of the original value. If this is the case, then proceed to step 12C.

    If the clear track current is more than ±20% of the original value a Full Test is required.

13. Check that all receivers drop with 0.8Ω across their connections which go out to the rails, and that 0.7 Ω at the transmitter connections which go out to the rails, drops all receivers in the track circuit.

    If the drop shunt tests pass, then proceed to 13C.

14. Record all values as required in the track Record Card.

    A full Set-Up procedure (APPENDIX E) should be carried out as soon as practically possible.

    Deferral of Setting Up and Testing, up to a limit of 48 hours, might be permitted on the basis of safety if this setup procedure is used.

This completes the RX set up.

NOTE: *Where Low Power or Low Power Plus tracks are used, the appropriate 'Low Power' or 'Low Power Plus' labels are required on the TX, RX and TUs / ETUs / SPETUs*

APPENDIX H - Digital Receiver Set Up Error codes

The automatic set-up failure code consists of 4 letters which are designed to focus the fault investigation:

- "M" indicates that the modulation rate is in error, e.g. mod pin stuck on high sideband.
- "S" indicates that the sideband imbalance is too great (exceeds 100%) suggesting a TU fault.

- "H" indicates that the input signal is too high suggesting the track should be moved to 'Low Power' or 'Low Power Plus'.
- "L" indicates that the input signal is too low suggesting open circuits / poor connections.

Message	Meaning of Code	Field Examples
L	Input signal low.	Over-long TC. Poorly set-up tuned area. Loose connections.
H	Input signal high	TC too short.
HL	Input signal high and low	Internal RX fault.
S	Sideband imbalance high	Failed TU.
SL	Sideband imbalance high and signal low	
SH	Sideband imbalance high and signal high	
SHL	Sideband imbalance high, signal high and low	Internal RX fault.
M	Mod rate incorrect	Faulty TX.
ML	Mod rate incorrect and signal low	Open circuit in TC. Wrong frequency TX or RX key.
MH	Mod rate incorrect and signal high	
MHL	Mod rate incorrect and signal high and low	Internal RX fault.
MS	Mod rate incorrect and sideband imbalance high	MOD pin tied on TX or TX MOD fault.
MSL	Mod rate incorrect, sideband imbalance high and signal low	Incorrect frequency key used.
MSH	Mod rate incorrect, sideband imbalance high and signal high	Unlikely to occur
MSHL	All signals incorrect	Internal RX fault.
Thld Tol	A-B mismatch between thresholds.	High level traction interference signal present.
Time Out	-	During the set up process when the set-up key is inserted - if 'OK' is not pressed within 60 seconds, the set up process will time out and the Threshold set to Zero.
Key Wrte	-	Faulty key or process corrupted.
WRNG	-	Set-up key inserted before frequency key or incorrect frequency key inserted to finish the process.

Table 17 - Typical Automatic Set-up Failure Codes

APPENDIX I - Error Codes

Error Code	Quantity / Error Code	Test	Display	Mtce. Action Required
0	Internal Circuit Fault	Circuit monitoring tests failed. This test has highest priority	'ERR' cycling with 'PICK' or 'drop' On pressing <OK> display routes to 'Stat' then pressing <OK> routes to 'INT'	Replace digital RX
1	Temperature	Error raised if internal temperature outside the range -30°C to +100°C	'ERR' cycling with 'PICK' or 'drop' On <OK> display routes to 'Temp'	Check Internal temperature of enclosure. If within temp. range then consider replacing digital RX
2	PSU Voltage	Error raised if PSU voltage outside the range +22V to +31V	'ERR' cycling with 'PICK' or 'drop' On <OK> display routes to 'Vpsu'	Check PSU setup.
3	Relay Current Note: Only relevant to MOD State 1 Dig RX.	Error raised if Relay Current exceeds 100mA.	'ERR' cycling with 'PICK' or 'drop' On <OK> display routes to 'Iout'	Check wiring and if no fault found replace digital RX
4	Relay Voltage	Error raised if Relay Voltage below 10V and output is ON.	'ERR' cycling with 'PICK' On <OK> display routes to 'Vout'	Check for a fault in the TR wiring, if no fault found change the Digital Rx
5	Relay State	Error raised if relay voltage > 10V and relay state = drop.	'ERR' cycling with 'drop' On <OK> display routes to 'Vout'	Check for a fault in the TR wiring, if no fault found change the Digital Rx
6	Modulation Frequency	Modulation Frequency out of range : 3.4Hz to 6.2Hz	'ERR' cycling with 'PICK' or 'drop' On <OK> display routes to 'Stat' then <OK> routes to 'MOD'	Check TC installation, however this is likely to be a TX fault. Change the TX.
7	Sideband Imbalance	Sideband imbalance out of specification. SB ratio exceeds 2:1.	'ERR' cycling with 'PICK' or 'drop' On <OK> display routes to 'Stat' then <OK> routes to 'SB'	Check TC installation, specifically TU/ETU, as this is not likely to be a digital RX fault. Carry out tests 1.16 to 1.19

Error Code	Quantity / Error Code	Test	Display	Mtce. Action Required
8	Over-range Signal	Input current exceeds 500mA	‘ERR’ cycling with ‘PICK’ or ‘drop’ On <OK> display routes to ‘Stat’ then <OK> routes to ‘OVR’	Check TC installation as this is not likely to be a digital RX fault. Check TU/ETU setting is on correct power mode.
9	Power Up			Not an error code. Timestamp of last power up.
10	Relay Current Trip Note: Only relevant to MOD State 1 Dig RX.	Relay current exceeds 110mA	‘ERR’ cycling with ‘drop’ On <OK> display routes to ‘Stat’ then <OK> routes to ‘TRIP’	Check TR wiring, if no fault found and TR is operating correctly, change the Digital RX.
10	Relay Power Trip MOD State 2 MOD State 3 Dig RX onwards	Relay power exceeds 2.4W 6.25W	‘ERR’ cycling with ‘drop’ On <OK> display routes to ‘Stat’ then <OK> routes to ‘TRIP’	Check TR wiring, if no fault found and TR is operating correctly, change the Digital RX.
11	FPGA Fail	One or both FPGA test flags are clear.	‘ERR’ cycling with ‘drop’ On <OK> display routes to ‘Stat’ then <OK> routes to ‘INT’	Replace digital RX
12	Auto set	An auto set has successfully occurred.		Not an error code. Time stamp of that last Auto set.
13	Relay Power Note: Only relevant for MOD State 2 Dig RX.	Error raised if Relay Power exceeds 2.2W.	‘ERR’ cycling with ‘PICK’ or ‘drop’ On <OK> display routes to ‘Pout’	Check TR wiring, if no fault found and TR is operating correctly, change the Digital RX.
13	Relay Current Applies to MOD State 3 Dig RX onwards	Error raised if Relay Current exceeds 260mA.	‘ERR’ cycling with ‘PICK’ or ‘drop’ On <OK> display routes to ‘Iout’	Check TR wiring, if no fault found and TR is operating correctly, change the Digital RX.
None	Assertion error	An assertion error occurs during normal operation.	‘ErSW’ displayed (Note: this error is not logged).	Replace the key as it could be a latent logging problem and cycle the unit's power. If ErSW appears again replace the unit and carry out an Autoset.

Error Code	Quantity / Error Code	Test	Display	Mtce. Action Required
None	Corrupt Key	Error raised if a corrupt key is detected upon initial insertion.	BADK	Replace frequency key and carry out an Auto set

These errors are not latched, i.e. if the quantity causing the error returns to normal, the 'ERR' display will be cleared and the fault relay energised. Note that the error is recorded in the error log.

The errors have a priority, 0 being the highest. If multiple errors exist then the only the highest priority error is shown. When it is cleared the next highest priority, error is shown.

The last error generated will be stored and made available as one of the data items over the serial link.

APPENDIX J - EBI Track 200 Frequencies

	Nominal	Lower Sideband	Upper Sideband
A	1699 Hz	1682 Hz	1716 Hz
B	2296 Hz	2279 Hz	2313 Hz
C	1996 Hz	1979 Hz	2013 Hz
D	2593 Hz	2576 Hz	2610 Hz
E	1549 Hz	1532 Hz	1566 Hz
F	2146 Hz	2129 Hz	2163 Hz
G	1848 Hz	1831 Hz	1865 Hz
H	2445 Hz	2428 Hz	2462 Hz

Table 18 - EBI Track 200 Frequencies

APPENDIX K - EBI Track 200 B3 3000 Impedance Bond Information

Frequency	Capacitance µF	Tolerance
A	308.23µF	± 1.5%
B	167.22µF	± 1.5%
C	222.07µF	± 1.5%
D	130.79µF	± 1.5%
E	373.41µF	± 1.5%
F	191.80µF	± 1.5%
G	259.76µF	± 1.5%

H	147.29µF	± 1.5%

Table 19 - Capacitor Box capacitance values

The Inductor in the Impedance Bond should be between 27.8µH – 28.2µH

END

1. General

The EBI Gate 200 Level Crossing System is an overlay system for use at footpaths, bridleways and UWC crossings. The system can be powered from a 110v/240v AC. supply or a solar/wind 24v DC. Supply.

The system can be configured for use on single or dual lines and has bi-directional capability.

Each line has two block sections and the system uses Frauscher RSR123 Wheel Sensors for train detection.

The distance of the normal direction strike-in (NDI) and the opposite direction strike-in (XDI) from the crossing varies depending on line speed and other design factors.

The wheel sensor at the crossing (NDO) on each line performs the input to one block section and the output to the adjacent block section.

Each wheel sensor is connected to an overvoltage protection unit (BSI005) in the EBI Gate 200 master unit by a 2 pair cable.

Each overvoltage protection unit is connected to a Frauscher ACS 2000 Evaluation Board (IMC).

The status of each block section is monitored by a Frauscher ACS 2000 Axle Counter Board (ACB).

The output of the Frauscher axle counter system (block section status) is used as the input to the safety rated PLC (programmable logic controller) architecture that determines the occupancy of the crossing approach block section.

The PLC drives the crossing user lights, audible warnings via safety rated IO Modules, it also provides auto-dial fault reporting and data logging capabilities.

Each crossing comprises of two EBI Gate units designated as master and slave. Both units contain Red/Green lights, audible warning units and the On-Demand mode push buttons (where required).

In addition, the master unit contains the PLC, IO modules, Battery backup/UPS, Frauscher axle counter units and power supply unit. The two units are connected by a 10 pair Plug Coupler cable.

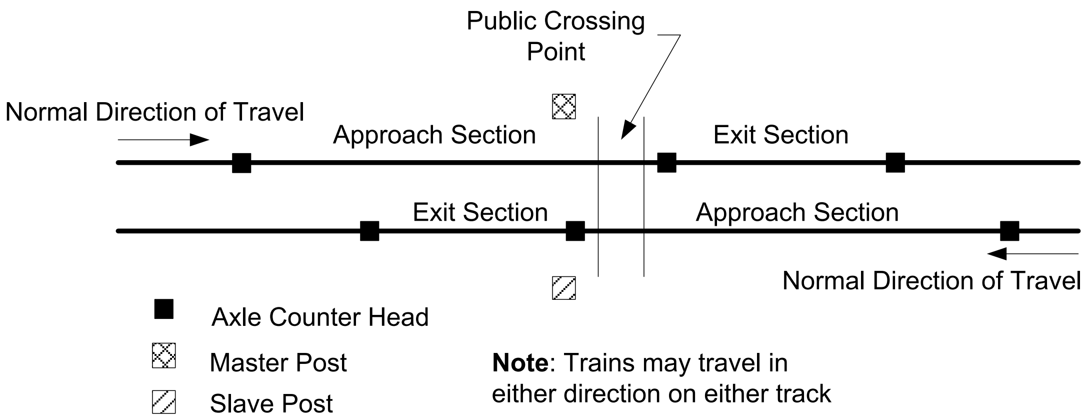

Figure 1 - A typical dual track system schematic

2. Operating Modes

The EBI Gate 200 Level Crossing System can be used in two modes.

a) Automatic.

b) On Demand.

In automatic mode the system operates as for a standard miniature red/green MSL crossing.

In On-Demand mode the user pushes a button located below the Red/Green lights on the EBI Gate 200 unit which when activated it displays a Green light if the crossing is available.

However, if the crossing is not available (train in section) at the time the button is activated then a Red light is displayed, and audible warning is given.

In “On-Demand” mode, when the button is pushed, and a Green or Red light is displayed. The system reverts to “energy saving” mode after a period of 5 minutes.

The EBI Gate 200 Level Crossing System gives another train warning tone and verbal warning on multi-track lines.

The EBI Gate 200 Level Crossing System has an inbuilt auto-restore facility and automatically sends a failure message followed by a system restored message to the designated monitoring point.

In the event that the system cannot restore itself the system sends a failed message to the monitoring point.

3. Test Equipment

The following items are used to complete all the testing and maintenance activities on Frauscher Advanced Counter equipment:

- Testing plate PB200.
- Test Box AMB100.
- Multi-meter, range 1000 mV DC, ± 0.5 % basic accuracy, internal resistance > 1 kΩ.
- 2 leads with 2 mm male connectors at both ends.
- Non-conductive cord (Plumb Line).
- Screwdriver (Flat-Headed Electrical Type).
- Tape measure.
- 30mm Spanner .
- 2.5mm Allan Key.
- Cord line and stepped treadle gauge.
- SD Card reading device (Laptop PC).

4. Wheel sensor RSR123

The wheel sensor RSR123 detects axles and consists of two sensor systems.

Viewed from the plug side, wheel sensor system 1 is on the left-hand side, wheel sensor system 2 is on the right-hand side.

Wheel sensor system 1 and 2 are symmetrically in design and are galvanically separated.

Two wires are allocated to each wheel sensor system. On the wheel sensor there is a four-wire cable connected via a plug connection, with a standard length of 5, 10 or 25 m. It is recommended to use a protection tube for the cable.

Figure 2 - Serial Number Location

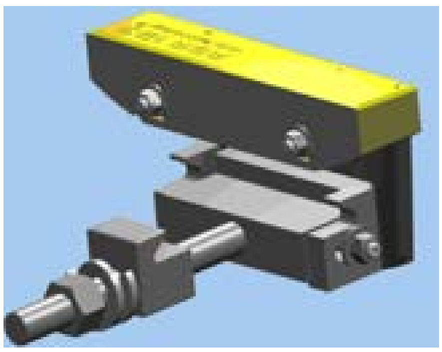

Figure 3 – General View

5. Axle Counter Evaluation Board (IMC)

The evaluation board is used to power and evaluate a wheel sensor with two sensor systems. The output switching signals are transmitted to the Axle Counting Board (ACB) via the Axle counting Back Plane (ABP).

Key to Board Image

Indication / Function	Meaning / Use
Serial Interface	Socket for diagnostic link
PWR	Supply voltage channel
Sys1	Illuminated - Illuminates when a wheel passes over Sys 1 sensor. This appears to flicker as each wheel passes over the sensor due to the speed of train. If A1 is permanently lit there is a cable fault.
A1	**Slow Flashing –** Cable or adjustment errors: Sys1 is either incorrectly connected, faulty, not adjusted, has a short circuit or an interruption in the supply line.
	Fast Flashing – Internal or operating error: The adjustment process was terminated; an invalid operation sequence was triggered (flash duration 2s) or an internal malfunction of the module has occurred. Turn the power supply of the IMC module off and on again!
	Short Flash – Wheel Sensor fault in Sys1: The life signal is lacking or there is an impermissible quiescent current drift.
B1	Illuminated - indicating switching its output when wheel detected.
A2	**Slow Flashing –** Cable or adjustment errors: Sys2 is either incorrectly connected, faulty, not adjusted, has a short circuit or an interruption in the supply line.
	Fast Flashing – Internal or operating error: The adjustment process was terminated; an invalid operation sequence was triggered (flash duration 2s) or an internal malfunction of the module has occurred. Turn the power supply of the IMC module off and on again!
	Short Flash – Wheel Sensor fault in Sys2: The life signal is lacking or there is an impermissible quiescent current drift.
	Slow Flashing – Cable or adjustment errors: Sys2 of the wheel sensor is either incorrectly connected, faulty, not adjusted, has a short circuit or an interruption in the supply line.
B2	Illuminated - indicating switching its output when wheel detected.
Adjust...	Is required to adjust the wheel sensor /IMC and to carry out a pre-Reset
Test	Damping of system 1
V+/GND	2 mm test sockets, voltage corresponds to the analogue wheel sensor current via a 100 Ω Shunt
nnn	Board identification code (IMC039)
xx…..yy	Month and Year of Manufacture
VDC	Operating voltage range (19 -72 volts DC)
ZZ	Version, beginning with 03

6. Axle Counter Board (ACB)

The ACB processes the counting head data supplied by the evaluation boards. Based on the data of the evaluation boards, the clear track or occupied track status of the track section to be controlled is determined and transmitted to the "clear/occupied" interface using direct output relays (potential-free).

Key to Board Image

Indication / Function	Meaning / Use
5v	Power supply
Occupied	Track section clear (not illuminated), track section occupied (illuminated) track section faulty (flashing).
Display	Number of axles in a track section, status information (error).
pre-Reset	Activated by pressing both buttons to the left at the same time to pre-reset the A/C heads.
Serial Interface	Socket for diagnostic link
nnn	Board identification code (ACB120)
xx…..yy	Month and Year of Manufacture
VDC	Operating voltage range (19 -72 volts DC)
ZZ	Version, beginning with 04

7. Fuse Board (SIC)

The SIC is used as supply voltage protection for ACS2000.

Indication / Function	Meaning / Use
Si1	Fuse for supply voltage at channel 1
Si2	Fuse for supply voltage at channel 2
nnn	Board identification code (SIC006)
xx…..yy	Month and Year of Manufacture
VDC	Operating voltage range (19 -72 volts DC)
ZZ	Version, beginning with 01

8. Axle Counter Board (ACB) Power Up Sequence Indications

Code				Meaning
L	R	N	0	No processor initialized, show for approximately 5 seconds
*	*	*	*	Flashing (successful initialization), show for approximately 10 seconds
-	1	0	9	The display alternates between the two codes indicating the ACB does not know the status of the axle counter section. At least one axle shall be correctly counted in and counted out.
-	2	0	9	
			0	Display status after axle in / axle out simulated.
/	/	/	/	If during power up a wheel sensor assigned to a track section is occupied
/	*	*	*	If a wheel sensor assigned to a track section is occupied during a serious or minor error.
S	C	I		A serial connection or communication has been interrupted / disrupted after power up but before reset. This can indicate a defective modem
B	O	O	T	This indicates a defective display processing unit. The ACB board should be
*	*	*	*	Not Flashing shown after power up and an axle count in or out.

9. Axle Counter Board (ACB) Diagnostic Indications

The ACB has a four-digit alphanumeric display. This is used to show the section axle count and also to show coded error/fault messages.

Codes that can be shown in display position 1**:**

Code				Meaning
-				Minor error or axle counted out
+				Minor error or axle counted in
/				One or more systems occupied
*				Steady, serious error
*				Flashing, error after reset

Codes that can be shown in display position 2:

Code				Meaning
	1			Channel 1 / System 1
	2			Channel 2 / System 2
	3			Channel 1 / System 1 of second axle counting board (second subsystem)
	4			Channel 2 / System 2 of second axle counting board (second subsystem)

10. Minor Error Codes, causes and actions Codes 00 to 7F (Hex)

Some of the codes that can be shown in display positions 3 and 4**:**

Code				**Brief Description**	**Cause**	**Action**
		0	0	No fault is present	fault-free operation	
		0	1	Another subsystem is reporting a minor error	see error code of the other subsystem	
		0	2	Another subsystem is not responding to the applied Reset	serial communication has been temporarily interrupted or disrupted (component error of a board)	repeat Reset, check the transmission medium, if necessary, replace the board
		0	3	Partial traversing on another subsystem	see error code of the other subsystem	
		0	4	Waiting for clearing of track after Reset (modem operation)	At least one axle shall be correctly counted in and out again, whereby one counting process shall take place on each subsystem (a train shall traverse from one subsystem to the other).	
		0	5	Occupied / clear comparison faulty in transmission mode.	EMC-interference (Hardware error)	Carry out a reset; if the error occurs again, replace the affected ACB.
		0	6	Negative axle in (modem operation)	For errors 21 to 26, if the serial communication is interrupted or disrupted.	Carry out a reset; if the error occurs again, replace the affected ACB.
		0	7	Pre-Reset carried out in (modem operation)	reset restriction removed through pre-Reset operation; the code is displayed after successful execution as confirmation.	
		0	8	Results of the counting logic and hardware evaluation	EMC-interference (Hardware error)	
		0	9	Waiting for clearing of track after Reset (isolated	At least one axle shall be correctly counted in and out again. This counting in and out process can be carried out at each counting head	
		0	A	Comparison of channel 1 and 2 faulty	overcurrent due to e.g. wire break, short circuit or interference on the wheel sensor cabling evaluation board has been removed or is not adjusted correctly Short circuit or interruption in double usage wiring evaluation board defective D|P-switches different wheel sensor has dropped off the track wheel sensor poles are reversed	
		0	B	Comparison of hardware evaluation 1 and 2 does not match		
		0	C	Negative axle in isolated operation	The same causes as with errors 21 to 26; display of this error code, if the serial communication is interrupted or disrupted.	

Code				Brief Description	Cause	Action
		0	E	Pre-Reset carried out in isolated operation	If a reset restriction has been removed with a pre-Reset operation, this code is displayed as confirmation after successful execution.	
		0	F	Failure of the serial communication	Serial communication (modem connection) is out of action for longer than 30 days.	Establish connection again; reverse the axle counting system by carrying out a simple reset.
		1	1	Partial traversing at the 1ST evaluation board.	Partial traversing e.g. during shunting works Very small wheel Check wheel sensor mounting (mounted too deep)	
		1	2	Partial traversing at the 2ND evaluation board.		
		1	3	Partial traversing at the 3RD evaluation board.		
		1	4	Partial traversing at the 4TH evaluation board.		
		1	5	Partial traversing at the 5TH evaluation board.		
		1	6	Partial traversing at the 6TH evaluation board.		
		2	1	Negative axle at the 1ST evaluation board.	System reset, with at least one axle in the track section Very small wheel Check wheel sensor mounting (mounted too deep)	
		2	2	Negative axle at the 2ND evaluation board.		
		2	3	Negative axle at the 3RD evaluation board.		
		2	4	Negative axle at the 4TH evaluation board.		
		2	5	Negative axle at the 5TH evaluation board.		
		2	6	Negative axle at the 6TH evaluation board.		
		3	1	System pulse of the 1ST evaluation board too short.	EMC-Interference Interference on the double usage wiring Evaluation board defective	If this error occurs with increasing frequency, the evaluation board affected should be replaced.
		3	2	System pulse of the 2ND evaluation board too short.		
		3	3	System pulse of the 3RD evaluation board too short.		

Code				Brief Description	Cause	Action
		3	4	System pulse of the 4TH evaluation board too short.		
		3	5	System pulse of the 5TH evaluation board too short.		
		3	6	System pulse of the 6TH evaluation board too short.		
		4	1	System 1 and 2 simultaneously on the 1st evaluation board	- Very large wheel - Wiring short circuit on the wheel sensor cabling - EMC-interference on the wheel sensor cabling - interference on the double usage wiring - check wheel sensor mounting (mounted too deep)	
		4	2	System 1 and 2 simultaneously on the 2nd evaluation board		
		4	3	System 1 and 2 simultaneously on the 3rd evaluation board		
		4	4	System 1 and 2 simultaneously on the 4th evaluation board		
		4	5	System 1 and 2 simultaneously on the 5th evaluation board		
		4	6	System 1 and 2 simultaneously on the 6th evaluation board		
		5	1	Pulse edge sequence not correct, too many edges at the 1st evaluation board	- EMC-interference - Very large wheel - Wiring short circuit on the wheel sensor cabling - EMC-interference on the wheel sensor cabling - interference on the double usage wiring	
		5	2	Pulse edge sequence not correct, too many edges at the 2nd evaluation board		
		5	3	Pulse edge sequence not correct, too many edges at the 3rd evaluation board		
		5	4	Pulse edge sequence not correct, too many edges at the 4th evaluation board		
		5	5	Pulse edge sequence not correct, too many edges at the 5th evaluation board		
		5	6	Pulse edge sequence not correct, too many edges at the 6th evaluation board		

Code				Brief Description	Cause	Action
		6	0	Relay Test	- Relay test active	unplug/plug relay
		6	1	The other subsystem is reporting clearing of track	- See error code of the other Subsystem	
		6	2	occupancy at the wrong time	- Defective wheel sensor - Defective evaluation board	
		7	1	Relay feedback faulty #1	An overcurrent due to e.g. wire break, short circuit or interference on the wheel sensor cabling short circuit or interruption in double usage wiring evaluation board defective - DIP-switches different relay contacts oxidised relay activation defective relay defective fault on the readback wire wheel sensor has dropped off the track wheel sensor poles are reversed	if this error occurs, troubleshooting should be executed in the sequence opposite (cause column); if necessary, the voltage supply should be interrupted and a reset should be carried out; if the fault occurs again, the affected ACB should be replaced.
		7	2	Relay feedback faulty #1		
		7	3	Relay feedback faulty #1		

#1. Detection of error during change from the clear to the occupied status or from the occupied to the clear status.

11. Serious Error Codes, causes and actions

Code				Brief Description	Cause	Action
		8	2	Power up, 4 asterisks are shown on the display.	Status after application of the supply voltage.	Reset required.
		8	3	Pre-Reset and Reset actuated at the simultaneously	- Pre-reset and Reset actuated at the simultaneously - Short circuit between the pre-reset and reset inputs	.
		8	4	DIP-switches changed during operation	- DIP-switches changed during operation.	Check diagrams for correct settings.
		9	0	Another sub-system is reporting a serious error	See error code on other sub- systems.	

Code				Brief Description	Cause	Action
		A	4	Relay feedback faulty #1	Relay contacts oxidized Relay activation defective Relay defective Fault on readback wire	If this error occurs the supply voltage should be interrupted, and a reset carried out. If it occurs again replace the affected ACB board.

#1 Detection of error during change from the clear to the occupied status or from the occupied to the clear status.

Code				Brief Description	Cause	Action
		D	0	Error in the program code test #2	- Program code faulty - EMC - interference	If this error occurs the supply voltage should be interrupted, and a reset carried out. If it occurs again replace the affected ACB board.
		D	1	Error in the data storage test #2	- SRAM faulty - EMC-interference	
		D	2	Error in the register test #2	- Register faulty - EMC-interference	
		D	3	Error in the Watch Dog Timer test #2	- Watch Dog Timer faulty - EMC-interference	
		D	4			
		D	5			
		D	6	Error in the overvoltage test #2	- Overvoltage Monitoring faulty - EMC-interference	
		D	7			
		D	8			
		D	9			
		D	A	Error in the read back input 2	- ACB faulty - EMC-interference	
		D	B			

#2. Detection of error during a power-up or caused by cyclical tests.

12. EBI Gate 200 System Messages

Message	Meaning
DAY LOG STATUS	System Periodic Test Ok This message sent on Power up and at 12:00 GMT every day.
RED DARK MODE ON	This message is sent if the crossing has entered Dark Mode and a successful reset has not occurred after 45 minutes. It continues to be sent every 45 minutes until the crossing has been restored.
GREEN SYSTEM RESTORED	This message is sent once the system is available to the user to display a red/green signal.
POWER FAILURE	This message sent on power failure

13. EBI Gate Abbreviations

Abbreviation	Meaning
ABP	Axle Counter Back Plane
ACB	Axle Counter Board
AMB100	Test Box
BSI	Overvoltage Protection Unit
IMC	Axle Counter Evaluation Board

Abbreviation	Meaning
NDI	Crossing Strike-in head in the normal direction of running
NDO	Crossing Strike-out head for both normal direction of running and bi-directional running
PB 200	Testing plate
RSR123	Wheel sensor type RSR123
Sys	Sensor system of a wheel sensor
SIP	Crossing Strike-in point
XDI	Crossing Strike-in head bi-directional running

14. Interpretation of the DataLog Files

In order to assist with the interpretation of the details shown in the columns of the DayLog this section contains expanded explanations of the details, grouped by column.

Column A - Date and Time

Date/Time	Explanation
01/02/70-00:00:15	Time/Date Stamp, DD/MM/YY-HH:MM:SS

Column B – Event

Event Description	Trigger
No Description	
1 Minute Check	Current Minute <> Last Log Minute
System Periodic Test OK	Logged on Power up and Mid-Day Only
Frauscher Reset	Frauscher Block Sections Reset after a “Self-Reset” or “Power Up”
AMBER Awaiting Train Reset	System has Initialised
GREEN System Restored	System Restored
Green Aspect On	The GREEN aspects have been illuminated on the posts
Green Aspect Off	The GREEN aspects have been switched off
Red Aspect On	The RED aspects have been illuminated on the posts
Red Aspect Off	The RED aspects have been switched off
RED Dark Mode On	Entering Dark Mode
Energy Save On	The Energy Save mode has activated
Demand Press	The “On-Demand” button has been pressed on either post
Manual Reset	Manual Reset has been carried out using the “Reset” Switch

Event Description	Trigger
Test Activated	System Test has been activated using the “Test” Switch
Audio 1 On	Audio 1 has been activated
Audio 1 Off	Audio 1 has been turned off
Audio 2 On	Audio 2 has been activated
Audio 2 Off	Audio 2 has been turned off
Open /Replace <file>	A file is open
Created: <File>	A new file is created
Train Update	Train Movement
Power Failure	Systems Power Lost
SMS Power Failure	Power failure Text Message
SMS Power Restored	Power Restored Text Message
Hardware Fault	System has entered an irrecoverable fault
Door open	Enclosure door open (Future Use)
Door Closed	Enclosure door Closed (Future Use)

Column D – Inputs

Block Input Message	Description
F	Sensor Fault
O	Transition State
FM	Block Clear
P	Block Occupied
DB	Demand Button Pressed
MR	Manual Reset

Inputs	Explanation
FM,--,--,--,--,--,--,--,	Block Section 1 Clear
P,--,--,--,--,--,--,--,	Block Section 1 Occupied
--,FM,--,--,--,--,--,--,	Block Section 2 Clear
--,P,--,--,--,--,--,--,	Block Section 2 Occupied
--,--,FM,--,--,--,--,--,	Block Section 3 Clear
--,--,P,--,--,--,--,--,	Block Section 3 Occupied
--,--,--,FM,--,--,--,--,	Block Section 4 Clear

Inputs	Explanation
--,--,--,P,--,--,--,--,	Block Section 4 Occupied
FM,FM,FM,FM,--,--,--,--,	All 4 Block Sections Clear
P,P,P,P,--,--,--,--,	All 4 Block Sections Occupied
DB,DB,DB,BD,--,--,--,--,	“On Demand” Button Pressed
MR,MR,MR,MR,--,--,--,--,	“Reset” Button Pressed

Column E - Block Status

Block Section Status	Description
CL	Block Section Clear
Oc	Occupied
WC	Waiting to Clear
I	Initialising
D1	Sensor Fail Timer
D2	Direction Timer Fail
RF	Red Fail Timer
GF	Green Fail Timer
HF	Hardware Fault
DM	Dark Mode
E	Energy Save Mode
--	Transition State

Inputs	Explanation
Cl,--,--,--,--,--,--,--,	Block Section 1 Clear
Oc,--,--,--,--,--,--,--,	Block Section 1 Occupied
WC,--,--,--,--,--,--,--,	Block Section 1 Waiting to Clear
I,--,--,--,--,--,--,--,	Block Section 1 In Initialization State
D1,--,--,--,--,--,--,--,	Block Section 1 Illegal Move Detected
D2--,--,--,--,--,--,--,	Block Section 1 Sensor Fail Timer

Inputs	Explanation
RF--,--,--,--,--,--,--,	Block Section 1 Direction Timer Fail
GF--,--,--,--,--,--,--,	Block Section 1 Red Fail Timer
HF--,--,--,--,--,--,--,	Block Section 1 Green Fail Timer
DM--,--,--,--,--,--,--,	Block Section 1 Hardware Fault
E--,--,--,--,--,--,--,	Block Section 1 Dark Mode

Column F - Status of Displayed Aspects

Aspect	Explanation
G,G,G,G,--,--,--,--,	GREEN Aspect Displayed
R,G,G,G,--,--,--,--,	RED Aspect Displayed Due to Block Section 1 Occupied
G,R,G,G,--,--,--,--,	RED Aspect Displayed Due to Block Section 2 Occupied
G,G,R,G,--,--,--,--,	RED Aspect Displayed Due to Block Section 3 Occupied
G,G,G,R,--,--,--,--,	RED Aspect Displayed Due to Block Section 4 Occupied
E,E,E,E,--,--,--,--,	Energy Save Mode. No Aspects Illuminated
--,--,--,--,--,--,--,--,	Aspect States During Initialization

15. Data Scenarios

To further improve the interpretation of the details the following DayLog extracts show the normal data sequences recorded for a number of scenarios.

Scenario 01- Up Road Train Normal Direction

Record	Date/Time	Event	Inputs	BlockStatus	Aspect	Explanation
47	01/11/13-00:36:34	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	No trains in the crossing area. 1 Min Checks occurring as expected.
48	01/11/13-00:37:35	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	
49	01/11/13-00:38:36	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	
50	01/11/13-00:39:36	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	
51	01/11/13-00:40:37	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	
52	01/11/13-00:41:37	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	

Record	Date/Time	Event	Inputs	BlockStatus	Aspect	Explanation
53	01/11/13-00:41:50	Train Update	P,FM,FM ,FM,--,--,--,--,	Oc,Cl,Cl,Cl,--,--,--,--,	R ,G,G,G ,--,--,--,--,	Block Section 1 is occupied by train
54	01/11/13-00:41:50	Green Aspect Off	P,FM,FM ,FM,--,--,--,--,	Oc,Cl,Cl,Cl,--,--,--,--,	R ,G,G,G ,--,--,--,--,	Green aspect turns off as Block Section 1 is occupied by train
55	01/11/13-00:41:50	Red Aspect On	P,FM,FM ,FM,--,--,--,--,	Oc,Cl,Cl,Cl,--,--,--,--,	R ,G,G,G ,--,--,--,--,	Red aspect turns on as Block Section 1 is
56	01/11/13-00:41:50	Audio 1 On	P,FM,FM ,FM,--,--,--,--,	Oc,Cl,Cl,Cl,--,--,--,--,	R ,G,G,G ,--,--,--,--,	Audio 1 turns on as Block Section 1 is occupied by train
57	01/11/13-00:42:18	Train Update	P,P,FM,FM ,--,--,--,--,	Oc,WC,Cl,Cl,--,--,--,--	R ,R ,G ,G ,--,--,--,--,	Train transitions the crossing, Block Section 1 and Block Section 2 is occupied by train
58	01/11/13-00:42:18	Train Update	FM,P,FM,FM ,--,--,--,--,	Cl,WC,Cl,Cl,--,--,--,--	G ,G ,G ,G ,--,--,--,--,	Green aspect turns on as train clears the crossing, Block Section 1 clears, and Block Section 2 is occupied by train
59	01/11/13-00:42:18	Green Aspect On	FM,P,FM,FM ,--,--,--,--,	Cl,WC,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	Green aspect turns on as train clears the crossing, Block Section 1 clears, and Block Section 2 is occupied by train
60	01/11/13-00:42:18	Red Aspect Off	FM,P,FM,FM ,--,--,--,--,	Cl,WC,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	Red aspect turns off as train clears the crossing, Block Section 1 clears, and Block Section 2 is occupied by train
61	01/11/13-00:42:18	Audio 1 Off	FM,P,FM,FM ,--,--,--,--,	Cl,WC,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	Audio 1 turns off as train clears the crossing, Block Section 1 clears, and Block Section 2 is occupied by train
62	01/11/13-00:42:39	Train Update	FM,P,FM,FM ,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	Train clears Block Section 2.
63	01/11/13-00:43:19	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	The train leaves the crossing Block Section 2 clears. 1 Min Checks resume.
64	01/11/13-00:44:19	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	No trains in the crossing area. 1 Min Checks occurring as expected.
65	01/11/13-00:45:20	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	No trains in the crossing area. 1 Min

Record	Date/Time	Event	Inputs	BlockStatus	Aspect	Explanation
66	01/11/13-00:46:20	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	Checks occurring as expected.
67	01/11/13-00:47:21	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	
68	01/11/13-00:48:21	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	

Scenario 02- Up Road Train Wrong Direction

Record	Date/Time	Event	Inputs	BlockStatus	Aspect	Explanation
50	01/11/13-00:39:36	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	No trains in the crossing area. 1 Min Checks occurring as expected.
51	01/11/13-00:40:37	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	
52	01/11/13-00:41:37	1 Min Check	FM,FM,FM,FM,--,--,--,--,	Cl,Cl,Cl,Cl,--,--,--,--,	G ,G ,G ,G ,--,--,--,--,	
53	01/11/13-00:41:50	Train Update	FM,**P** ,FM,FM,--,--,--,--,	Cl,Oc,Cl,Cl,--,--,--,--,	G ,R ,G ,G,--,--,--,--,	Block Section 2 is occupied by train
54	01/11/13-00:41:50	Green Aspect Off	FM,**P** ,FM,FM,--,--,--,--,	Cl,Oc,Cl,Cl,--,--,--,--,	G ,R ,G ,G,--,--,--,--,	Green aspect turns off as Block Section 2 is occupied by train
55	01/11/13-00:41:50	Red Aspect On	FM,**P** ,FM,FM,--,--,--,--,	Cl,Oc,Cl,Cl,--,--,--,--,	G ,R ,G ,G,--,--,--,--,	Red aspect turns on as Block Section 2 is occupied by train
56	01/11/13-00:41:50	Audio 1 On	FM,**P** ,FM,FM,--,--,--,--,	Cl,Oc,Cl,Cl,--,--,--,--,	G ,R ,G ,G,--,--,--,--,	Audio 1 turns on as Block Section 2 is occupied by train

Includes:	EBI Track 400 Audio Frequency Track Circuit
Excludes:	All other Track Circuits

1. EBI Track 400 Audio Track Circuit: GENERAL

This document provides technical information for the setting up, faulting and maintenance of EBI Track 400 track circuits.

Under no circumstances shall the TX and RX tuning units of one track circuit be disconnected from the rails at the same time.

This can allow unwanted power to pass between the adjacent track circuits resulting in a possible failure of an abutting track circuit.

The TU cables form part of the tuned circuit, because of this they should wherever possible be bound together, not allowed to form loops and not be run in parallel with the running rails. Failure to observe these items can result in the effectiveness of the tuned area being altered i.e. low or below specification readings.

Numerous parameters are usually accessible via Remote Condition Monitoring and can be used to assist with fault investigations.

1.1. EBI Track 400 Layout Configurations

EBI Track 400 track circuits can be used in a number of configurations:

a) Double rail configuration using TUs for jointless or ETUs for jointed track circuits using Open Line frequencies.

b) Double rail configuration using SATUs for jointless or CUs for jointed track circuits using Station Area frequencies.

c) Single rail configuration using ETUs, SPETUs.

d) Both single rail and double rail configurations can have multiple Receivers/Track Relays.

1.2. Warning:

If an RX or TX is disconnected from its tuning unit, the terminals on that tuning unit to which the 2-core cable was attached shall be short circuited.

A double rail EBI Track 400 track circuit shall never be reconfigured as a single rail track circuit.

1.3. Caution:

The gain or sensitivity shall not be increased or decreased where the clear track current (across IPC-IP1 OL, IPC-IP2 SA.) has changed by more than 10% without consulting your S(MS).

Any adjustment should only be to obtain the correct drop shunt, for that track circuit.

Tuned zones shall be kept clear of all metallic objects including new or scrap lengths of rail for a distance of at least 1.25m (4ft). The tail cables from the TU to the rails form part of the tuned circuit, because of this they should wherever possible be bound together, not allowed to form loops and not be run in parallel with the running rails. Failure to observe these items can result in the effectiveness of the tuned area being altered i.e. low or below specification readings.

1.4. Power Supplies and Fusing

EBI Track 400 utilises PULS power supplies which provide a stabilised 48VDC. The 110VAC supply to the power supplies are fused with 5A BS88 Joint Services Fuse. The 48VDC supply to Transmitters use 5A and 7A BS88 Joint Services Fuse depending on the feed lengths and Receivers use a 3A BS88 Joint Services Fuse. BS88 fuses are mandated for reliability.

1.5. Test Equipment

A TI21 Test Meter (TTM), TI21-M Test Meter (MTM) or EBI Track Track Circuit Meter (ETTCM) set to the frequency of the track circuit under test shall be used for voltage measurements. It is not acceptable to test EBI Track 400 without a TTM, MTM or ETTCM.

A Rail current measuring devices such as a Rocoil or Lemflex, used in conjunction with the TTM/MTM/ETTCM, can be used to measure the EBI Track 400 current in the rail to locate a section of the track bed causing loss of power at the Receiver end.

1.6. Centre Fed and Cut Section Track Circuits

Each half of a centre fed track circuit or each cut section operates as an independent track circuit and shall be tested as such and record cards kept for each part.

1.7. Impedance Bond Tuning

Any impedance bonds within the track circuit shall be tuned with the correct resonating capacitor across the auxiliary coil or in the case of B3 3000 and B3 500 bonds (which have no auxiliary coil) the correct tuning module.

Each removable tuning capacitor / module is labelled with the style of bond it should be fitted to. Where it is not removable this information appears on the bond itself.

If the earlier PCB type of tuner board (e.g. Howells or WH3 type) is used, the correct links shall be cut depending on the track circuit frequency.

1.8. Rail to Rail Voltage

With the track circuit not shunted by a train or train shunt the rail-to-rail voltage should fall approximately linearly from the TX to the RX end. In exceptional circumstances (and with permission of the S&T Maintenance Engineer) it may be raised by intermediate tuning capacitors.

1.9. Rail Current

The EBI Track 400 rail current reading gives a more useful reading, than rail voltages, and should be virtually constant throughout the track circuit length. It should also be of similar values in both rails.

Where impedance bonds, or intermediate tuning capacitors (Bucking Capacitors) have been fitted the current value will have a marked change. Significant changes in track current indicate leakage faults between the rails which should be investigated and rectified.

It should be noted that PAN 8 and Bullhead rail will inherently lose current because of the lack of pads and nylons.

1.10. Tuned Zone Ratios (Pole/Zero Ratios)

Pole – Track under test
Zero – Adjacent/abutting track

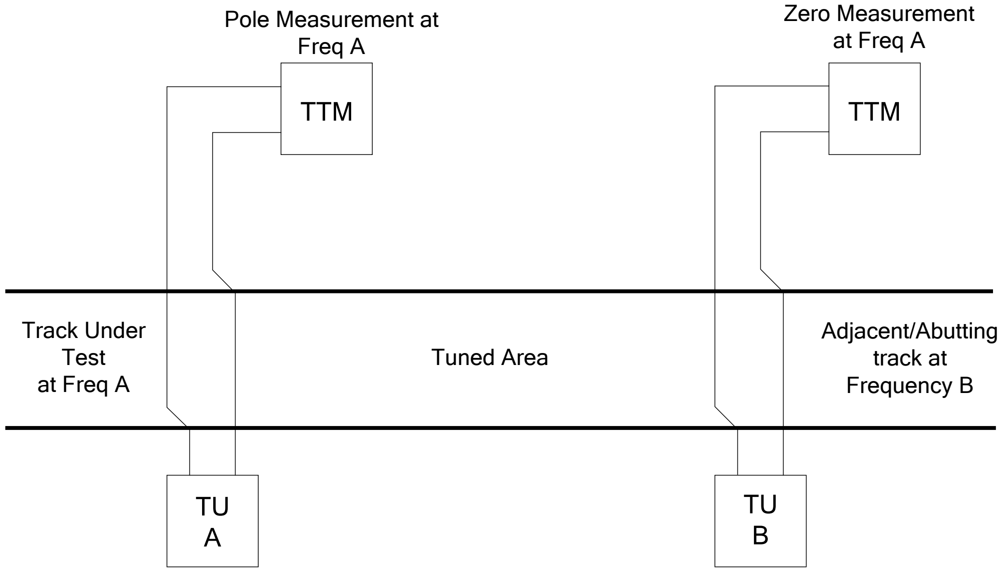

Figure 1 – Tuned Zone Ratio Pole Zero Positions

The Pole voltage is the voltage across the rails at the TU of the track under test (TU A in drawing) at that track's frequency (Frequency A in Figure 1). For the purpose of the test this TU can be called the 'Pole TU'.

The zero voltage is measured across the companion tuning unit's (TU B in the drawing) rail terminals at the track under test frequency (Frequency A in the drawing). For the purpose of the test this TU can be called the 'Zero TU'.

Important points to note are:

a) The pole/zero measurement gives no information about the quality of the pole. The pole is the property in the tuning unit which determines how much signal current is sent down the track to the RX at the other end.

b) The pole/zero measurement will give a good measurement of the quality of the zero. The zero determines how much unwanted signal flows into the adjacent track.

c) The quality of the zero is determined by the impedances caused by:

- The components within the TU.
- The tightness of the track and TU connections.
- The layout of the track cables.
- The equipment (TX/RX) connected to the zero TU.

From the above statements, the following conclusions can be reached:

a) Pole/zero ratios are a good method of monitoring the quality of the TU connections and track cable layout. As such, they provide evidence that good installation practice has been followed.

b) If pole/zero ratios are measured with an active TX connected to the zero TU, then the ratio will be degraded.

1.11. Mechanical and Electrical Connections

Good quality mechanical and electrical connections are important to obtain reliable operation of the EBI Track 400 equipment.

These connections shall be made and maintained in accordance with the torque requirements defined in Appendix G.

1.12. Spare/Scrap Rail Laid in the 4ft

Placing spare/scrap rail in the 4ft should not affect the operation of the track circuit.

However, if placing spare/scrap rail through a Tuned Zone is unavoidable, the following actions will mitigate against unreliable operation:

a) Measure the current flowing in the rail laid in the 4ft using a Rocoil. This should be Zero.

If current is found to be flowing in the rail, then there is likely to be physical contact between the running rails and the spare rail. This should be rectified.

b) Check the TZR before and after the rail is laid in the 4ft. If the change in TZR is less than 10%, there should not be any further problems. This check should be repeated when the rail is removed from the 4ft.

1.13. TU/ETU/SPETU hoods (Acoustic Jackets)

These should be fitted in areas close to residential property where noise might cause a nuisance.

1.14. Intermediate Tuning Capacitors

These are used to increase the gain at intermediate positions in the track circuit to overcome low ballast resistance caused by poor formation and/or rail fastenings.

They shall not be fitted or removed without permission from the S&T Maintenance Engineer.

They require individually specified drop shunt testing along the length of the track circuit at increased frequency.

1.15. Transmitter and OM3 Failures

Transmitter and OM3 failures will generally result in a hard failure of the track causing it to show occupied. If these items are replaced, either individually or both at the same time, and the OM3 set up in accordance with the switch setting information from the record card and provided the receiver is not changed; then a check of the clear track current will determine how much testing is required before the track is returned to operational service.

If, after the equipment is replaced, the clear track current is within 10% of the clear track current recorded, **at Commissioning**, on the record card then a full test shall be carried out in accordance with the defined procedures.

If the clear track current has changed by more than 10% then the receivers shall be set up again followed by carrying out a full test in accordance with the defined procedures.

1.16. Receiver Current

RX current is measured at the RX input terminals (IP1 & IPC for Open Line tracks, IP2 & IPC for Station Area tracks) with a TTM, MTM, ETTCM or by using the display. This is the actual physical quantity that the track circuit uses to determine the presence/absence of a train and so is a direct measure of the overall health of the track circuit.

1.17. Receiver Current – General

The RX current is affected by:

a) The quality of the TX pole.
b) The quality of the RX pole.
c) Ballast resistance.
d) Feed through from adjacent track circuits of the same frequency.

From the previous statements, the following conclusions can be reached:

RX current is an excellent overall measure of the stability of the track circuit. Significant changes in current are due to either degradation in the TUs, or changes in the leakage current between the rails. e.g. impedance bonds, rail bonds, check rails etc.

A significant deviation is indicated if the change of track current is greater than:

±20% OR

±10mA.

These factors require investigation if fault-free operation is to be maintained'.

1.18. Tuned Zones

Pole/zero ratios are useful in monitoring installation standards.

RX current is the most effective measure of track circuit performance and stability since it measures the effectiveness of the pole circuit and signal leakage effects.

1.19. Tuned Zones on Steel Sleepers

Special instructions for tuned zone installations shall be followed:

a) Open Line Tuned zone is 22m ± 0.5m.
b) Station Area Tuned Zone is 5m ± 0.1m.
c) All the sleepers within the zone, and for 3 bays either side, are of a Network Rail accepted steel type.

There have been instances of re-railing where concrete/timber sleepers have been replaced by steel sleepers and the tuned zone has not been changed accordingly.

Where an EBI Track 400 Tuned Zone on steel sleepers is found to be not installed to 22m+/-0.5m, it shall be reported as corrective maintenance.

1.20. Single Rail Application

RX current can be affected by the quality of the rail connections, bonded out joints, IRJ's and S&C insulations (sole plates, stretcher bars etc).

1.21. Testing for Crosstalk / Feed through

Where it is required to test and check for crosstalk / feed through values, the procedure below is to be performed:

Check that all track circuits which can cause interference to the track circuit being tested are operational, including:

(a) The next track circuits of the same frequency.
(b) Track circuits connected to the track circuit under test by cross bonding.

Switch off the transmitter associated with the tack circuit under test, and check that the track relay de-energises.

Using the Receivers Condition Monitoring display, record the value 'Inow (AV)' on the track circuit record card as part of the record for the test and check for permitted values against Table 1.

Track Circuit Configuration	Crosstalk / Feed Through Max (mA)
Double Rail Open Line frequency Track Circuits	8mA
Single Rail Open Line frequency Track Circuits (with 30m Bonding/Cross Bonding)	3mA
Double Rail Station Area frequency Track Circuits	Less than 10% of Ith or 20mA whichever is the lower

Table 1 – Crosstalk / Feed Through values

Where a SR track circuit is identified as not having the 30m bonding/cross bonding:

- The crosstalk / feed through could be higher than 3mA. A crosstalk / feed through value of greater than 8ma should be investigated for corrective action.

- The track circuit should be reported for corrective action to apply the 30m bonding/cross bonding.

A current higher than the stated maximum values should be investigated. Look for disconnected or incorrect bonding, tuning unit failure, etc.

2. Fault Finding - Guidelines

2.1. General

Before starting work, all track connections shall be checked for tightness as described in NR/SMS/PartC/TC17 (Track Circuits: EBI Track 400).

The generic EBI Track 400 Bombardier Manuals can be also referenced.

The health of a track circuit can be determined by the voltage measured across IPC-IP1 OL, IPC-IP2 SA . Any changes to the TX/OM3 output level, the TX or RX ETU, SPETU, TU, SATU or CU the track bed or associated tuned zone equipment will affect the receiver input current.

The track relay voltage will indicate the correct functioning of the RX and that the relay coil is not damaged. If the relay coil voltage is low, it will indicate a failing RX unit.

The relay end rail voltage is a measure of the energisation level of the track circuit. It will change inversely proportional to the drop shunt value and will be affected by the same factors. A low rail voltage will indicate a faulty TU/ETU/SPETU/SATU/CU or a faulty connection at any part of the track.

If two adjacent track circuits fail simultaneously, the fault is most likely where the two tracks adjoin. Check the tuning units and associated connections and other shared equipment like the PSU.

For centre fed track circuits any problem within 30 metres of the centre feed will affect both sections.

If low ballast resistance is suspected see if the problem can be localised. On concrete sleepered track check the pads and clip insulations. On timber sleepered track check for poor ballast drainage and P8 type rail fastenings. If the problem can be isolated, spot replacement of rail insulations or replacement of P8 fastenings with P14 shall be considered. (if you are in doubt about the type of fastenings, ask your Supervisor).

Checking obtained readings against those on the Record Card and investigating those that have significantly changed can reveal the source of the fault.

Using a TTM/MTM/ETTCM a measurement of the rail-to-rail voltage at regular intervals from TX to RX should show a gradual decrease of the voltage.

Rail current readings give a more valued reading than track voltage.

2.2. Open Line Frequency Tracks

2.2.1. OL Track Circuit Tests – General

WARNING

High voltages can be present at the EBI Track 400 Transmitter Output Module terminals, line matching unit terminals and at receiver output terminals.

Before fitting or removing these units, power shall be removed from the associated transmitter or receiver. Personnel delegated to work on these units while in operation, shall be suitably competent.

Do not allow the output of the Output Module to become short-circuited.

The OM3 resistor shall remain switched to the 0R position in "Open Line" operation.

If the OM3 resistor is found not switched to the 0R position, this shall only be corrected with permission from the S&T Maintenance Engineer.

Observe all safety procedures that are in force for track possession, and for working on or near the track.

NOTE: *High voltages can be present at rail connections due to traction currents.*

IMPORTANT

Before disconnecting any Tuning Unit rail connections, both track circuits adjacent to the affected track are switched off. This is because the disconnected TU can have formed the short circuit that prevented energy from one adjacent track feeding through to the other. There is a danger of false feeding a track circuit and causing a wrong side failure if this precaution is not observed and another Tuning Unit were to become disconnected.

Short circuiting connections to a TU or disconnecting a transmitter or receiver from a TU can cause a right side failure by dropping the companion track circuit (the track circuit that shares the tuned area being tested with the track that is under investigation).

Measurements of voltage and current of the EBI Track 400 frequency signal for a track can be corrupted by signals from the companion track and other AC sources. To overcome this problem, a TTM/ETTCM, set to the frequency of the track circuit under test, should be used for all readings. If a TTM/ETTCM is not available, to reduce the problem, the Transmitter of the companion track should be switched off as follows:

(1) Always switch off the companion Transmitter if it shares the tuned area being tested. Switch off by removing a power supply fuse - do not disconnect the Transmitter from the Tuning Unit as this will upset the "pole" tuning.

(2) When signal levels less than or equal to receive end rail voltages are being measured, switch off the companion Transmitter even if it is remote from the tuned area being tested.

Unless a TTM/ETTCM is used, there is always a danger that interference from other tracks or 50 Hz mains can reduce the accuracy of measurements. In electrified areas measurements should not be made when a train is nearby on any line in case harmonics in the traction current at EBI Track 400 frequencies corrupt the readings. A TTM/ETTCM will not satisfactorily filter out other signals within 30 Hz of that selected for measurement.

The TTM/ETTCM could be influenced by strong magnetic fields. Consequently it is advisable that a TTM/ETTCM is not placed directly onto traction current carrying components, such as running rails, impedance bonds, traction return cables, etc. Also, on some schemes with concrete track beds there is the possibility of stray currents flowing in concrete reinforcements of the track bed.

2.2.2. Open Line Tests – Track Circuits with TUs / ETUs

Confirmation of the source of the fault can be achieved by use of the track circuit tests next described. Some measurements can be made by using the Condition Monitoring System (CMS).

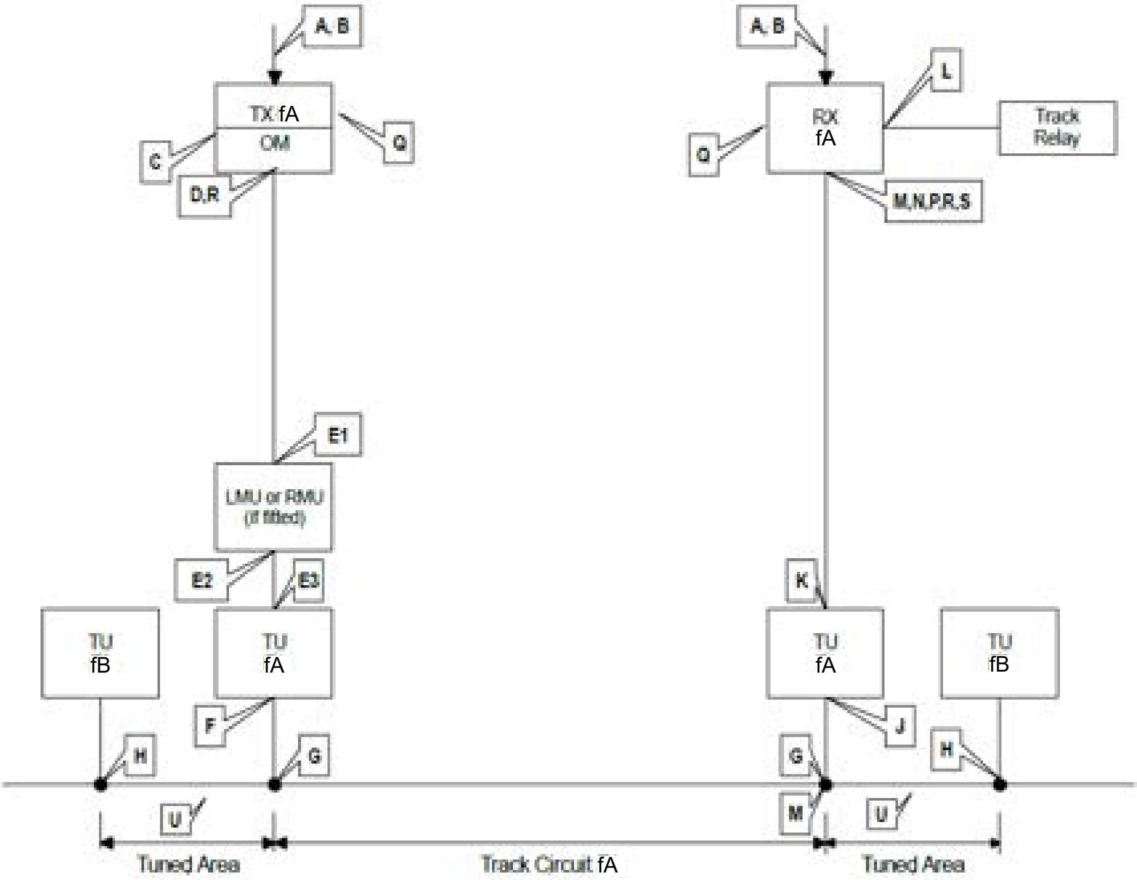

Figure 2 – Summary of Tests for track Circuits with TUs / ETUs

The Table 2 indicates the acceptable limits for each of the parameters measured at the above test points “A” to” H”.

Measurements can be taken by alternative methods as indicated.

- CMD= Condition Monitoring Display on Tx or Rx.
- DVM= Digital Multimeter.
- TTM = TI21 Track Circuit Meter.
- ETTCM = EBI Track Track Circuit Meter.

Test	Measurement	CMD	TTM or ETTCM	DVM	Normal Range
A	Tx 48V input current.	-	-	√	Depends on track and feed cable length, see Appendix C - Transmitter Current Consumption (Max).
A	Rx 48V input current. Relay down	-	-	√	Approx. 50mA DC
A	Rx 48V input current. Relay up	-	-	√	100mA to 150mA DC

Test	Measurement	CMD	TTM or ETTCM	DVM	Normal Range
B	Tx & Rx Power Supply Input voltage	"Vpsu"	-	√	47.5V to 48.5V DC
C	Tx Voltage out.		√	√ see note 1a	32V to 34V rms
D	Output Module output voltage	"Vout"	-	√ see note 1b	OM3 depends on switch setting see Appendix D - Output Module (OM3) Output Level v Step Setting. **0R switch shall be set to 0R**
	Output Module output power	"Pout"	-	-	"Pout" should be greater than 1.5W indicating that the Tx is supplying power to the line. "Pout" rises with Tx-to-track distances and track length up to a maximum of 200W.
E1	LMU(TU) Input Voltage	-	-	√ see note 1b	50V to 148V RMS (increases with Tx to TU feed length)
E2	LMU(TU) Output Voltage	-	√	√ see note 1a	0.6V to 15 V rms
E3	TU/ETU Input Voltage. Terminals 4 & 5	-	√	√ see note 1a	20m – 250m: 0.6V to 2.0V 250m – 1100m: 5V to 15V rms
F	TU Output Voltage	-	√	√ see note 1a	Values should be 5% to 10% Higher than Test G
G	Tx End Rail to Rail Voltage	-	√	√ see note 1a	Values should meet Appendix A - Typical Rail-to-Rail Voltages.
H	Tuned Area Voltage ratios. (see note 3)	-	√	-	Minimal acceptable ratios indicated in Appendix B. (See note 2).
J	Rx TU Input Voltage. Terminals T1 & T2	-	√	-	Values should meet Appendix A - Typical Rail-to-Rail Voltages.
K	Rx TU Output Voltage. Terminals 1 & 2	-	√	-	Lower than Test J. (See note 2).

Test	Measurement	CMD	TTM or ETTCM	DVM	Normal Range
L	Receiver output Voltage to Relay	√ “Vout”	√	√	50V relay version: 48 to 52VDC (Mod state 2 and later) 40 to 44VDC (Mod state 1) 24V relay version: 23 to 27VDC (Mod state 2 and later) 19 to 22VDC (Mod state 1)
M	Rx Drop Shunt at Rx end of TC. TC length > 250m	-	-	-	0.8 Ohm to 1.2 Ohm (see note 4.)
M	Rx Drop Shunt at Rx end of TC. TC length < 250m	-	-	-	1.3 Ohm to 1.7 Ohm (see note 4.)
N	Rx Input current	√ “Inow”	√	-	30-380mA. Value should be within ±20% of value recorded at last set up. See note 5.
P	Cross-talk and Feed-through test	√ “Inow”	√	-	Less than 8mA. (see note 6.)
Q	Earth Connection continuity	-	-	-	See note 7
R	Check that surge arrestor line terminals are isolated from earth.	-	-	√	>100kΩ
S	Total Wide-band current (3Hz-33kHz)	“ITot”	-	-	This level should be noted as it can be used to ascertain the bleed through and cross talk of the tuned zone. It shall be less than 500mA
T	Impedance Bond Test	-	√	-	The impedance of an impedance bond can be checked by measuring the voltage across the bond and the current through it at the track circuit frequency. To take the current measurements use a Rocoil connected to a TTM/ETTCM. • Check all rail connections and bonding are tightened to the correct torque. • Check the security and the fixing of the tuning module. • Place the Rocoil over the rail 1 metre before the Bond (TX side) and note the reading on the TTM/ETTCM (= amps, I_1). • Repeat the measurement 1 metre from the bond on the RX side (= amps, I_2).

Test	Measurement	CMD	TTM or ETTCM	DVM	Normal Range
					• Subtract I_2 from I_1 thus obtaining the current through the bond at the EBI Track 400 frequency. • If an ETU is connected directly to the bond, then a current clamp able to wrap around the ETU lead and feed into the TTM/ETTCM (eg a Fluke i3000s Flex-24) shall be used as follows. Place the current clamp around the ETU lead and note the reading on the TTM/ETTCM (= amps, I_3). This value will be subtracted from the previously calculated current, thus obtaining the current through the bond at the EBI Track 400 frequency. • Measure the rail to rail voltage (V) across the impedance bond. • Divide the voltage (V) by the current calculated above thus giving the impedance (Z), $Z = V / (I_1 - I_2)$. This value shall be greater than 8 Ω. If this is not the case, check that the correct tuning module has been fitted.
U	Spare Rail in the Tuned Zone Test	-	√	-	Measure the current flowing in the rail laid in the 4ft using a Rocoil. This should be Zero. If current is found to be flowing in the rail, then there is likely to be physical contact between the running rails and the spare rail. This should be rectified. Check the Tuned Zone Ratio (Test H) before and after the rail is laid in the 4ft. If the change in Ratio is less than 10%, there should not be any further problems. This check should be repeated when the rail is removed from the 4ft.

Table 2 – Summary of Tests for track circuits with TUs / ETUs

These notes and Test Letter references in Sections 2.2.3 to 2.2.6 to be read in conjunction with the Table above.

Note 1a. Use a TTM/ETTCM set to the appropriate voltage range and TC frequency. If a TTM/ETTCM is not available use a DVM that is suitable for measuring true rms voltages at frequencies up to 3kHz.

Note 1b. Use a DVM that is suitable for measuring true rms voltages at frequencies up to 3kHz or a ETTCM. Do not use a TTM. Do not allow the Output Module’s output to become short-circuited.

Note 2. To measure receive end voltage, the TU output terminals 1 and 2 shall be connected to the Receiver or short circuited - do not leave them open circuit.

Note 3. The voltage measured across the rail connections of the companion, or “Zero”, Tuning Unit should be lower than that across the “Pole“ Tuning Unit of area. All measurements are taken at the ‘Pole’ frequency. The voltage ratio is calculated as voltage at G divided by voltage at H.

Note 4. It is only necessary to carry out a drop shunt test at the receive end Tuning Unit rail connections since similar or higher values will be found elsewhere in the TC except within the tuned area which is a special case.

Under no circumstances shall a TC be left with a drop shunt less than 0.5 Ohm in the main part of the track circuit.

Note 5. As a cross check on the CMD measurement, the value of Receiver input current can also be measured by checking, with a TTM/ETTCM, the voltage developed across the 1Ω resistor (which is connected in series with the input of the Receiver). One mV so measured equates to One mA.

The minimum value of input current (the Threshold Current) necessary for an Rx to pick up its Track Relay can be read directly from the Rx display by accessing the quantity “Ith” since this is the value locked into the Rx during the automatic set-up process.

Note 6. Check that all track circuits which can cause interference to the TC under test are operational, including:

a) The next TC of the same frequency.
b) TCs connected to the TC under test by cross bonding.

Switch off the Tx associated with the TC under test and check that the Track Relay de-energises and that the Receiver input current is less than 8mA. An Rx input current higher than 8mA shall be investigated

Note 7. Confirm by continuity checks that the Tx, Rx and PSU cases are connected to the local earth. Also confirm that all lightning protection earth terminals are connected to earth. The earth connection resistance must not be greater than 50Ω.

WARNING

Do not use a TTM to measure the output from an Output Module and its corresponding LMU(TU) input (ETTCM can be used). Beware that the voltages on these units can exceed 150V RMS.

NOTE: *The 2mm Test leads have a rated maximum operating voltage of 30VAC and 60VDC.*

This voltage is high enough to endanger life; before fitting or removing these units, power shall be removed from the associated EBI Track 400 Transmitter.

2.2.3. OL Fault Finding - General

If adjacent track circuits fail together, then items common to them - power supplies, Tuning Units or interconnections - should be checked first.

The most vulnerable parts of the track circuit are the TU / ETU-to-rail and impedance bond-to-rail connections. It is prudent to check the integrity of these before beginning a systematic test through the circuit from the transmit end. It is also advisable to check that there is no fault in the wiring between the receiver output, track relay and the panel indication before proceeding to the trackside

Full details of the tests are given in Section 2.2.2. It is important not to simply overcome a fault by adjusting the receiver gain; the reason for a change in drop shunt value should be ascertained by performing the tests given in this section. The results of each test can be compared with the measurements taken at the last test / commissioning / setting-up that were logged on the record card; any major differences can be a guide to the possible fault area. Although the tests are presented to start from the transmit end of the track circuit, sometimes it can be more convenient to start from the receive end.

2.2.4. OL Fault Finding - Transmitter End

1. Check that the Transmitter and Tuning Unit / End Termination Unit are making a 'singing' noise (The volume of this will vary depending on cable and track length).

   Use the Condition Monitor to ascertain that the Tx and OM3 output are correct (i.e. display does not show 'ERR'). If the Transmitter is showing 'ERR' then press 'OK' and follow the CM menu structure to find the cause of the error.

   a) If the Transmitter is not 'singing' and the Tx Status indicates an internal or frequency fault, then the Transmitter is faulty and should be changed.

   b) If the Transmitter is not 'singing' and ''Vout' is zero, or very low then check the connections between the Output Module and the Tx. If these are OK, then the Transmitter is faulty and should be changed.

   c) If 'Vout' is in range but 'Pout' is zero, or very low, then this indicates that the Output Module is disconnected from its TU/ETU.

2. Test the integrity of the Tx to rail path by connecting a 1.0Ω shunt across the Transmitter TU rail connections. This should reduce the rail-to-rail voltage by approximately half if the transmit end is working properly. If this test is successful then the remainder of the Transmitter tests need not then be carried out.

3. Test the +48 power supply voltage and current to the Transmitter (Tests A and B), and the Transmitter and Output Module output voltage (Tests C and D). Results from these tests outside the normal range show that the power supply unit, Transmitter or Tuning Unit / End Termination Unit can be faulty. Further tests will help to indicate which has failed but only replacement of the most suspect unit can finally establish which is faulty.

4. Tuning Unit input and output voltages (Tests E3 and G) will show whether the interconnections are OK.

5. The results of Test D and E1 will indicate whether the inter-wiring between Tx/LMU(TU) is serviceable.

WARNING

Do not use a TTM to measure the output from an Output Module and its corresponding LMU(TU) input. ETTCM can be used. Beware that the voltages on these units can exceed 150V RMS.

NOTE: *The 2mm Test leads have a rated maximum operating voltage of 30VAC and 60VDC.*

This voltage is high enough to endanger life; before fitting or removing these units, power shall be removed from the associated EBI Track 400 Transmitter.

6. If the rail-to-rail voltage (Test G, step 4 above) is wrong, then either of the TUs, or the rail connections can be faulty.

   The companion TU voltage should be tested (Test H). If incorrect, then the companion TU can be faulty. The companion TU will be confirmed as faulty if the rail-to-rail voltage at the TU of the failed track becomes correct when terminal T1 is shorted to terminal T2 on the companion TU.

   If the transmit end appears to work normally, walk through the track checking bonds and insulation pads, and look for any metal debris that can be shorting it out.

   The rail current should fall only very slowly between the Transmitter and Receiver ends. During the walk through, it should be checked every 20m, or 50m if a long track, and the difference between any two consecutive readings should be about the same. Any sharp falls in current indicate a problem with the track itself. The place where the irregularity occurs can be used as a guide to the location of the track fault.

   See section 2.2.6 for further information on track faults.

2.2.5. OL Fault Finding - Receiver End

1. Check the voltage at the Tuning Unit rail connections (Test J). A low reading indicates that either TU can be faulty or that a connection has failed.

2. The voltage at the companion TU should be tested (Test H). If incorrect, then the companion TU can be faulty. The companion TU will be confirmed as faulty if the rail-to-rail voltage at the TU of the failed track becomes correct when terminal T1 is shorted to terminal T2 on the companion TU.

3. Measure the Receiver input current (Test N). If this is significantly lower than the clear track current recorded on the record sheet, i.e. more than 20% less, the Receiver TU is faulty. If it is adequate but there is insufficient relay supply voltage (Test L) with a satisfactory power supply (Tests A and B), then change the Receiver.

4. Check the connections to the relay, and that the voltage is available on the coil terminals. Change the relay if necessary.

2.2.6. OL Fault Finding - Track Related problems

If all the standard tests detailed in sections 2.2.3 to 2.2.5 do not reveal a fault and problems persist, then the fault is probably due to excessive leakage of track circuit signal current. The causes of leakage fall into three main groups:

Individual sleeper leakage paths	Chair bolts touching reinforcing in concrete sleeper and either no or failed insulation system (pads & biscuits between rail and chairs).
Localised. leakage paths	Track running through a ‘wet bed’ or over a road crossing where contamination has occurred (e.g. lorries carrying coal or minerals).
General ‘background’ leakage	Old track on wooden sleepers without insulation system between rails and chairs

In the case of localised leakage and individual sleeper problems, the most effective means of identifying the problem area is by use of a Rocoil Rail Current Transducer and TTM/ETTCM using the following method;

The Rail Current Transducer is connected to the TTM/ETTCM and the meter switched to the correct frequency for the track circuit under investigation. Current flowing onto the track circuit from the End Termination Unit should first be measured.

The current level in each rail should be the same; this should be checked since a difference of more than about 10% should be investigated. Differences in current between the two rails indicate that there is a third path through which some of the feed or return current is flowing. This could be a path through the ground (or ballast), but is more likely to be via traction bonding or other rails or tracks. Such paths should be eliminated as far as possible since they can only reduce the sensitivity of the track circuit to train shunts by providing alternative paths that are not shunted.

Areas where current can be significantly different in each rail are in points and crossings. It is sometimes the case that one rail splits to form two parallel paths, e.g. via the diamond of a crossing. In this case about half of the track circuit current will flow in each path, and it will not be possible to change this.

In areas of plain line, assuming the current in both rails is the same, it is not normally necessary to continue measuring in both rails. The current in the rail should be measured at convenient intervals, say 20m to 50m, until a larger than normal decrease is noted. The poor ballast area or shorting sleeper will be within this area. Further readings can now be taken to narrow down the precise area of leakage, or the shorting sleeper.

2.3. Station Area Frequency Tracks with SATU/CU

2.3.1. SA Track Circuit Tests - General

WARNING

High voltages can be present at the EBI Track 400 Transmitter Output Module terminals, tuning unit terminals and at Receiver output terminals. Before fitting or removing these units, power shall be removed from the associated Transmitter or Receiver. Personnel delegated to work on these units while in operation, shall be suitably competent.

Do not allow the output of the Output Module to become short-circuited.

Observe all Safety Procedures that are in force for track possession, and for working on or near the track. Note that high voltages can be present at rail connections due to traction currents.

IMPORTANT

It is important that, before disconnecting any tuning unit rail connections, both track circuits adjacent to the affected track are switched off. This is because the disconnected SATU could have formed the short circuit that prevented energy from one adjacent track feeding through to the other. There is a danger of false feeding a Track Circuit and causing a wrong side failure if this precaution is not observed and another tuning unit were to become disconnected.

Beware, also, that short circuiting connections to a SATU or disconnecting a Transmitter or Receiver from a SATU can cause a right side failure by dropping the companion track circuit.

Measurements of voltage and current of the EBI Track 400 frequency signal for a track can be corrupted by signals from the companion track and other AC sources. To overcome this problem, a MTM/ETTCM, set to the frequency of the Track Circuit under test, should be used for all readings. If a MTM/ETTCM is not available, to reduce the problem, the Transmitter of the companion track should be switched off as follows:

(1) Always switch off the companion Transmitter if it shares the tuned area being tested. Switch off by removing a power supply fuse, or dis-engage the TX frequency key - do not disconnect the Transmitter from the Tuning Unit as this will upset the "pole" tuning.

(2) When signal levels less than or equal to receive end rail voltages are being measured, switch off the companion Transmitter even if it is remote from the tuned area being tested.

Unless an MTM/EETCM is used, there is always a danger that interference from other tracks or 50 Hz mains can reduce the accuracy of measurements. In electrified areas measurements should not be made when a train is nearby on any line lest harmonics in the traction current at EBI Track 400 frequencies corrupt the readings. An MTM/ETTCM will not satisfactorily filter out other signals within ±100 Hz of that selected for measurement.

Note that the MTM/ETTCM could be influenced by strong magnetic fields. Consequently it is advisable that an MTM/ETTCM is not placed directly onto traction current carrying components, such as running rails, impedance bonds, traction return cables, etc. Also, on some schemes with concrete track beds there is the possibility of stray currents flowing in concrete reinforcements of the track bed.

2.3.2. SA Tests – Track Circuits with SATUs / CUs

Problems with Track Circuit operation can be indicated in a number of ways. The most common is nuisance dropping of the track relay when trains are not present. Some faults, e.g. Tx frequency out of specification, low power supply voltage or an internal logic fault in the Tx or Rx, are indicated directly on the Transmitter or Receiver Condition Monitoring Displays (CMD). Other problems require the source of the fault to be discovered by use of the Track Circuit tests in Figure 3.

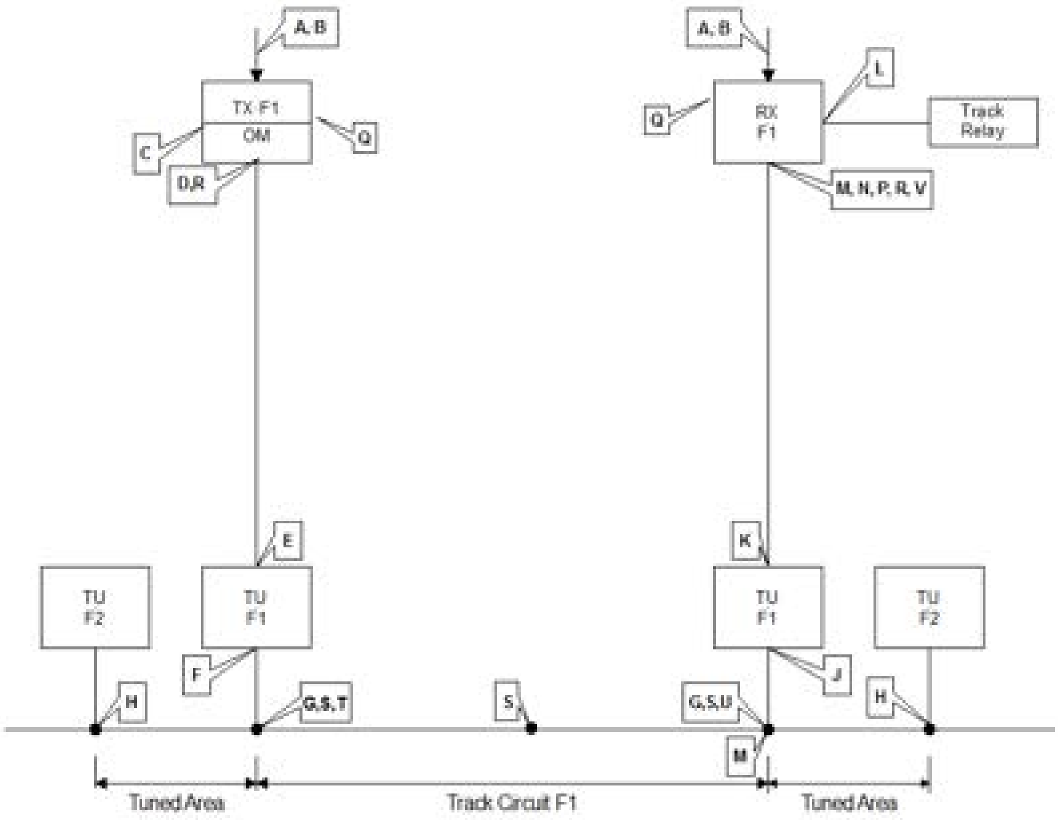

Figure 3 – Summary of Tests for track Circuits with SATUs / CUs

The Table 3 indicates the acceptable limits for each of the parameters measured at the above test points "A" to" H".

Measurements can be taken by alternative methods as indicated.

- CMD= Condition Monitoring Display on Tx or Rx.
- DVM= Digital Multimeter.
- MTM =TI21-M Track Circuit Meter.
- ETTCM = EBI Track Track Circuit Meter.

Test	Measurement	CMD	MTM or ETTCM	DVM	Normal Range
A	Tx 48V input current.	-	-	√	1.5A to 6A DC
A	Rx 48V input current. Relay down	-	-	√	Approx. 50mA DC
A	Rx 48V input current. Relay up	-	-	√	100mA to 150mA DC
B	Tx & Rx Power Supply Input voltage	"Vpsu"	-	√	47.5V to 48.5V DC

Test	Measurement	CMD	MTM or ETTCM	DVM	Normal Range
C	Tx Voltage out.		√	√ see note 1a	33V AC rms
D	Output Module output voltage	"Vout"	-	√ see note 1b	If resistor switch set to 0R; The OM3 output voltage depends on switch setting, see Appendix D - Output Module (OM3) Output Level v Step Setting. If resistor switch set to 48R; Resistor switch shall be set to 48R when a SATU or CU is used with a feed length less than 750m. The OM drive level shall be 13 or lower and the open circuit output voltage shall be less than 95V.
	Output Module output power	"Pout"	-	-	"Pout" should be greater than 1.5W indicating that the Tx is supplying power to the line. "Pout" rises with Tx-to-track distances and track length until the maximum SATU/CU input voltage is reached. The maximum SATU/CU input voltage shall be no more than $95V_{RMS}$.
E	SATU/CU Input Voltage at terminals LINE 1 & 2.	-	√	√ see note 1b	Line losses mean that this figure will be less than that measured in D. Voltage will rise with Tx-to-track distances and track length until the maximum level of 95V is reached. This level shall not be exceeded.
F	SATU/CU Output Voltage	-	√	√ see note 1a	Values should be 5% to 10% Higher than Test G (see note 4)
G	Tx End Rail to Rail Voltage	-	√	√ see note 1a	Values should meet Appendix A.
H	Tuned Area Voltage ratios. (see note 3)	-	√	-	Minimal acceptable ratios 3:1 for F1, F3, F4 & F5 5:1 for F2, F4, F6 & F8 (See note 2 & 4)
J	Rx SATU/CU Input Voltage at terminals T1 & T2	-	√	-	Record value for use in test K.

Test	Measurement	CMD	MTM or ETTCM	DVM	Normal Range
K	Rx SATU/CU Output Voltage. Terminals LINE 1 & 2	-	√	-	30% lower than Test J. (See note 2 & 4).
L	Receiver output Voltage to Relay	√ “Vout”	√	√	50V relay version: 48 to 52VDC (Mod state 2 and later) 40 to 44VDC (Mod state 1) 24V relay version: 23 to 27VDC (Mod state 2 and later) 19 to 22VDC (Mod state 1)
M	Rx Drop Shunt at Rx end of TC.	-	-	-	1.0Ω to 3.0Ω
N	Rx Input current	√ “Inow”	√	-	Should be within 25% of the Rx I/P current recorded during last set-up. See note 5.
P	Cross-talk and Feed-through test	√ “Inow”	√	-	Less than 10% of ‘Ith’ or 20mA whichever is the lower. A higher level shall be investigated (look for disconnected cable screens, SATU failure, etc). (See note 6)
Q	Earth Connection continuity.	-	-	-	See note 7
R	Check that surge arrestor line terminals are isolated from earth.	-	-	√	>100kΩ
S	Set a shunt box to 0.2Ω and carry out a shunt test at the following points in the track circuit: Tx pole, Mid-point, Rx pole and At the end of the deviation of a points track.	√ “Inow”	-	-	Track shall drop. Record Rx current at each point with the shunt in place.

Test	Measurement	CMD	MTM or ETTCM	DVM	Normal Range
T	Calculate the Tx TZ impedance: $TZimp = \left(\frac{CT}{Ish} - 1\right) xRsh$ CT = Receiver input current (Iav) Measured when track is clear Ish =Receiver input current (Iav) measured when a 1Ω shunt has been applied at the Tx end rail connections.	√ "Inow"	-	-	TZimp shall be >0.4Ω
U	Calculate the Rx TZ impedance: $TZimp = \left(\frac{CT}{Ish} - 1\right) x\ 1.5$ CT = Receiver input current (Iav) Measured when track is clear Ish = Receiver input current (Iav) measured when a 1Ω shunt has been applied at the Rx end rail connections.	√ "Inow"	-	-	TZimp shall be >0.4Ω
V	Total Wide-band current (3Hz to 33kHz)	"ITot"	-	-	"ITot" shall be less than 500mA. This level should be noted as it can be used to ascertain the bleed through and cross talk of the tuned zone.
Y	Impedance Bond Test	-	√		The impedance of an impedance bond can be checked by measuring the voltage across the bond and the current through it at the track circuit frequency. To take the current measurements use a Rocoil connected to a MTM/ ETTCM.

Test	Measurement	CMD	MTM or ETTCM	DVM	Normal Range
					• Check all rail connections and bonds are tightened to the correct torque. • Check the security and the fixing of the tuning module. • Place the Rocoil over the rail 1 metre before the Bond (TX side) and note the reading on the MTM/ETTCM (= amps, I_1). • Repeat the measurement 1 metre from the bond on the RX side. • Subtract I_2 from I_1 thus obtaining the current through the bond at the *EBI* Track 400 SA frequency. • If an CU is connected directly to the bond, then a current clamp able to wrap around the CU lead and feed into the MTM/ETTCM (eg a Fluke i3000s Flex-24) shall be used as follows. Place the current clamp around the CU lead and note the reading on the MTM/ETTCM (= amps, I_3). This value will be subtracted from the previously calculated current, thus obtaining the current through the bond at the *EBI* Track 400 SA frequency. • Measure the rail to rail voltage (V) across the impedance bond. Divide the voltage (V) by the current calculated above thus giving the impedance (Z), Z= V / (I1-I2). This value shall be greater than 8 Ω. If this is not the case, check that the correct tuning module has been fitted.

Table 3 - Summary of Tests for track Circuits with SATUs / CUs

These notes and Test Letter references in Sections 2.3.3 to 2.3.6 be read in conjunction with the Table above.

Note 1a. Use an MTM/ETTCM set to the appropriate voltage range and TC frequency. If an MTM/ETTCM is not available use a DVM that is suitable for measuring true rms voltages at frequencies up to 10kHz.

Note 1b. Use a DVM that is suitable for measuring true rms voltages at frequencies up to 10kHz. Do not use a MTM/ETTCM. Do not allow the Output Module's output to become shot-circuited.

Note 2. To measure receive end voltage, the SATU/CU LINE 1 & 2 shall be connected to the Receiver or short circuited-do not leave the open circuit.

Note 3. The voltage measured across the rail connections of the companion, or "Zero", Tuning Unit should be lower than that across the "Pole" Tuning Unit of area. All measurements are taken at the 'Pole' frequency. The voltage ratio is calculated as voltage at G divided by voltage at H.

Note 4. When taking test measurements at SATU terminals that have been coated with contact treatment grease, check that a good contact is made, if necessary clean the relevant terminals with a suitable cleaning agent and apply further grease after the measurements have been taken.

Note 5. As a cross check on the CMD measurement, the value of Receiver input current can also be measured by checking, with an MTM/ETTCM, the voltage developed across the 1 Ohm resistor (which is connected in series with the input of the Receiver). One mV so measured equates to one mA.

The minimum value of input current (the Threshold Current) necessary for an Rx to pick up its Track Relay can be read directly from the Rx display by accessing the quantity "Ith" since this is the value locked into the Rx during the automatic set-up process.

Note 6. Check that all track circuits which can cause interference to the TC under test are operational, including:

(a) the next TC of the same frequency.
(b) TCs connected to the TC under test by cross bonding.

Switch off the Tx associated with the TC under test and check that the Track Relay de-energises. The only suitable meter for this test is an MTM/ETTCM. A general purpose DVM shall not be used.

Note 7. Confirm by continuity checks that the Tx, Rx and PSU cases are connected to the local earth. Also confirm that all lightning protection earth terminals are connected to earth. The earth connection resistance must not be greater than 50Ω.

WARNING

Do not use an MTM/ETTCM to measure the output from an Output Module and its corresponding SATU or CU input. Beware that the voltages on these units can exceed 150V RMS.

This voltage is high enough to endanger life; before fitting or removing these units, power shall be removed from the associated EBI Track 400 Transmitter.

Do not allow the output of the OM3 to become short circuited.

2.3.3. SA Fault Finding – General

If adjacent track circuits fail together, then items common to them - power supplies, tuning units or interconnections - should be checked first.

The most vulnerable parts of the track circuit are the SATU / CU-to-rail and impedance bond-to-rail connections. It is prudent to check the integrity of these before beginning a systematic test through the circuit from the transmit end. It is also advisable to check that there is no fault in the wiring between the receiver output, track relay and the panel indication before proceeding to the trackside.

Full details of the tests are given in Section 2.3.2. It is important not to simply overcome a fault by adjusting the receiver gain; the reason for a change in drop shunt value should be ascertained by performing the tests given in this section. The results of each test can be compared with the measurements taken at the last test / commissioning / setting-up that were logged on the Record card; any major differences can be a guide to the possible fault area. Although the tests are presented to start from the transmit end of the track circuit, sometimes it can be more convenient to start from the receive end.

2.3.4. SA Fault Finding - Transmitter End

1. Check that the Transmitter and SATU / CU are making a 'singing' noise (the volume of this will vary depending on cable and track length).

   Use the Condition Monitor to ascertain that the Tx and OM3 output are correct (i.e. display does not show ‘ERR’). If the Transmitter is showing ‘ERR’ then press ‘OK’ and follow the CM menu structure to find the cause of the error.

   - If the Transmitter is not ‘singing’ and the Tx Status indicates an internal or frequency fault, then the Transmitter is faulty and should be changed.
   - If the Transmitter is not ‘singing’ and ‘’Vout’ is zero, or very low then check the connections between the output module and the Tx. If these are OK, then the Transmitter is faulty and should be changed.
   - If ‘Vout’ is in range but ‘Pout’ is zero, or very low, then this indicates that the output module is disconnected from its SATU/CU.

2. Test the integrity of the Tx to rail path by connecting a 2.0Ω shunt across the Transmitter SATU rail connections. This should reduce the rail-to-rail voltage by approximately 25% if the transmit end is working properly. If this test is successful then the remainder of the Transmitter tests need not then be carried out.

3. Test the +48 power supply voltage and current to the Transmitter (Tests A and B), and the Transmitter and Output Module output voltage (Test C and D). Results from these tests outside the normal range show that the power supply unit, Transmitter or Tuning Unit / Coupling Unit can be faulty. Further tests will help to indicate which has failed but only replacement of the most suspect unit can finally establish which is faulty.

4. Tuning Unit input and output voltages (Tests E and F) will show whether the interconnections are OK.

WARNING

Do not use an MTM/ETTCM to measure the output from an Output Module and its corresponding SATU or CU input. Beware that the voltages on these units can exceed 150V RMS.

This voltage is high enough to endanger life; before fitting or removing these units, power shall be removed from the associated EBI Track 400 Transmitter.

5. If the rail-to-rail voltage (Test G) is wrong, then either of the SATU/CU, or the rail connections can be faulty.

   The companion SATU voltage should be tested (Test H). If incorrect, then the companion SATU can be faulty. The companion SATU will be confirmed as faulty if the rail-to-rail voltage at the SATU of the failed track becomes correct when terminal T1 is shorted to terminal T2 on the companion SATU.

   If the transmit end appears to work normally, walk through the track checking bonds and insulation pads, and looking for any metal debris that can be shorting it out.

   The rail current should fall only very slowly between the Transmitter and Receiver ends. During the walk through, it should be checked every 20m or 50m and the difference between any two consecutive readings should be about the same. Any sharp falls in current indicate a problem with the track itself. The place where the irregularity occurs can be used as a guide to the location of the track fault.

   See Section 2.3.6 for further information on track faults.

2.3.5. SA Fault Finding - Receiver End

1. Check the voltage at the tuning unit rail connections (Test F). A low reading indicates that either SATU can be faulty or that a connection has failed.

2. The voltage at the companion SATU should be tested (Test H). If incorrect, then the companion SATU can be faulty. The companion SATU will be confirmed as faulty if the rail-to-rail voltage at the SATU of the failed track becomes correct when terminal T1 is shorted to terminal T2 on the companion SATU.

3. Measure the Receiver input current (Test N). If this is significantly lower than the clear track Rx input current recorded on the record sheet, i.e. reduced by more than 20%, the Receiver SATU is faulty. If it is adequate but there is insufficient relay supply voltage (Test L) with a satisfactory power supply (Tests A and B), then change the Receiver.

4. Check the connections to the relay, and that the voltage is available on the coil terminals. Change the relay if necessary.

2.3.6. SA Fault Finding - Track Related problems

If all the standard tests detailed in sections 2.3.3 to 2.3.5 do not reveal a fault and problems persist, then the fault is probably due to excessive leakage of Track Circuit signal current. The causes of leakage fall into three main groups:

Individual sleeper leakage paths	Chair bolts touching reinforcing in concrete sleeper and either no or failed insulation system (pads & biscuits between rail and chairs).
Localised. leakage paths	Track running through a ‘wet bed’ or over a road crossing where contamination has occurred (e.g. lorries carrying coal or minerals).
General ‘background’ leakage	Old track on wooden sleepers without insulation system between rails and chairs

In the case of localised leakage and individual sleeper problems, the most effective means of identifying the problem area is by use of a Rail Current Transducer and MTM/ETTCM using the following method.

The Rail Current Transducer (e.g.Rocoil) is connected to the MTM/ETTCM and the meter switched to the correct frequency for the Track Circuit under investigation. Current flowing onto the Track Circuit from the Coupling Unit should first be measured.

The current level in each rail should be the same; this should be checked since a difference of more than about 10% should be investigated. Differences in current between the two rails indicate that there is a third path through which some of the feed or return current is flowing. This could be a path through the ground (or ballast), but is more likely to be via traction bonding or other rails or tracks. Such paths should be eliminated as far as possible since they can only reduce the sensitivity of the Track Circuit to train shunts by providing alternative paths that are not shunted.

Areas where current can be significantly different in each rail are in points and crossings. It is sometimes the case that one rail splits to form two parallel paths, e.g. via the diamond of a crossing. In this case about half of the Track Circuit current will flow in each path, and it will not be possible to change this.

In areas of plain line, assuming the current in both rails is the same, it is not normally necessary to continue measuring in both rails. The current in the rail should be measured at convenient intervals, say 20m to 50m, until a larger than normal decrease is noted. The poor ballast area or shorting sleeper will be within this area. Further readings can now be taken to narrow down the precise area of leakage, or the shorting sleeper.

2.4. Impedance Bonds (Where Fitted)

Before checking the impedance bond(s) the TX equipment shall first be proved to be operating correctly.

1. Check that no corrosion, dirt oil or water is present in the terminal box and/or connection points.

2. Check the Advance plate to Centre Tap connection has be made using the bolted spreader plates in accordance with the Network Rail defined procedures.

3. Check the Impedance Bond has been installed and sitting on a rubber Conformance Pad.

4. Check the Impedance Bond has been installed with the appropriate insulating covers depending on the Impedance Bond type.

5. Measure the voltage across the auxiliary coil or tuning module (NOT applicable to B3 3000 and B3 500 bonds), check it is in the correct ratio with the rail-to-rail voltage (Appendix C). If it is correct the bond should be operating correctly, if it is incorrect proceed with the next step.

6. Check the tuning capacitor/module is correct for the style of bond and the track circuit frequency. Apply a short circuit across the tuning capacitor/module and measure the voltage.

7. Remove the short circuit and check the voltage rises. If there is not a dramatic rise in voltage replace the tuning capacitor/module. If it still does not improve matters consider replacing the bond.

Near ETU units this tuning capacitor/module test might not work.

For intermediate bonds only - the impedance of any impedance bond can be checked by following steps 7 to 11.

8. Place the Rocoil over the rail 1 metre before the Bond (TX side) and note the reading on the TTM/ETTCM (= amps, I1).

9. Repeat the measurement 1 metre from the bond on the RX side (I2).

10. Subtract I2 from I1 thus obtaining the current through the bond at the EBI Track frequency.

11. Measure the rail to rail voltage (V) across the impedance bond.

12. Divide the voltage (V) by the current calculated from step 9 above thus giving the impedance (Z),

$$Z = V / (I1 - I2)$$

This value should be greater than 8Ω. If less than 8Ω, check for traction imbalance before remedial action is taken with the impedance bond. (The Manufacturers specification is 12Ω when measured at the Capacitor frequency).

It is possible to verify the Impedance Bond is within the manufacturers specification by measuring the Bond inductance without the tuning capacitor connected. The value should be between 27.8 to 28.2 μHenries.

The value between the rail connections and the centre tap will be half these values.

2.5. Interference Test

To check the traction interference levels on the track the following tests are carried out on T1-T2 terminals of the ETU/TU/SATU/CU.

For traction areas only:

1. Remove the B24 fuse to the TX and check the correct track relay drops.

2. Measure the voltage across the track using a TTM/ETTCM set to AC 200mV range. Measure the frequency across the track using a multimeter.

3. Record both the voltage and frequency readings.

4. Readings greater than 100mV are un-acceptable, the track circuit shall be investigated and your SM(S) informed.

If there is a problem, this test can be repeated with the traction supply OFF as this can help to identify the source of the interference.

If all the readings appear to be correct but the track circuit remains failed then recheck all items above and check there are no problems arising from spare / scrap rail laid in the 4ft.

3. Appendix A - Typical Rail-to-Rail Voltages

TRACK LENGTH (m)	Tx to TRACK LENGTH (km)	MAX Tx END VOLTAGE (V)		MAX Rx END VOLTAGE (V)	
		A, C, E, G	B, D, F, H	A, C, E, G	B, D, F, H
100	<2	3.0	4.5	1.0	1.6
100	6	2.0	2.8	0.4	0.5

Table 9 - Output Module (OM3) Output Level v Step Setting

7. Appendix E - Open Line Frequencies – Double Rail - Setup Configuration Routine

7.1. Open Line Frequencies Setup : Initial Configuration

Step	Transmitter	Receiver
0	Transmitter with no key inserted. Transmitter key of the correct frequency available for use. This key contains a unique code for any market area. The key colour shall be the correct one for the market area - blue With no key in place the display indicates "KEY?"	Receiver key starts off programmed for frequency only. The key colour shall be the correct one for the market area – blue. With no key in place the display indicates "KEY?" If an un-coded Rx key is inserted in the Rx the Rx will respond with BLNK
1	Adjust the Output Module to step 1 and the resistor to 0R. **Note The Resistor shall remain in the 0R position and is not be used to adjust the output level.**	
2	Configuration process starts by inserting the Tx key in the Tx. This configures Tx for code and frequency. The display will first confirm key frequency as"400X" for 1 second, where "X" = one of eight frequencies A to H, followed by the key serial no. for 1 second and "RUN" when fully active and emitting signals	
3	If Rx keys are required to be programmed, then remove Tx key. Display will again indicate "KEY?"	

Step	Transmitter	Receiver
4	Insert the Rx key to be coded (shall be the same frequency as the Tx key being copied)" The display will respond by indicating "CPY?" Press the "OK" pushbutton. Display responds "TxK?" Remove Rx key and replace with Tx key. Display responds with "RxK?" Remove Tx key and replace with Rx key. The display will change to "PASS" which indicates that the Rx key has been successfully programmed with the correct code.	
5	Repeat item 4 with subsequent Rx keys if multiple Rx are used.	
6	Remove last Rx key and re-fit the Tx code and frequency key. The display will first confirm key frequency as "400X" for 1 second where "X" = one of eight frequencies A to H, followed by "KEY S/N" for 1 second and "RUN" when fully active and emitting signals.	
7		Insert a programmed Rx key in Rx. The display will first confirm key frequency as"400X" for 1 second where "X" = one of eight frequencies A to H, followed by "KEY S/N" for 1 second and "NewK" when fully active. Rx can display "drop" or "PICK" when fully active if the Rx key was programmed and used for the track circuit previously. Rx now active and ready for set up.

Step	Transmitter	Receiver
8		Perform the TC set up routine as per section 7.2 - Open Line Frequencies Setup : Set-up Routine
Fault indications during the Initial Configuration Routine. If at any step of the initial configuration routine the Transmitter or Receiver displays differ from those indicated above then the table below shows the likely reasons.		
Note: Tx keys cannot be reprogrammed to a new code or frequency. Rx keys can be programmed to a new code, but cannot be reprogrammed to a new frequency.		

Table 10 - Open Line Frequencies Setup : Initial Configuration

Tx or Rx Display	Fault
Rx display “ERR” cycling with “drop” Tx display “ERR” cycling with “stop” On OK display changes to “STAT” On OK display changes to “INT”	Internal circuit fault with unit. See Note 1
Rx display “ERR” cycling with “PICK” or “drop” Tx display “ERR” cycling with “RUN” On OK display changes to ”TEMP”	Temperature has exceeded the temperature range -30°C to + 100°C. See Note 1
Rx display “ERR” cycling with “PICK” or “drop” Tx display “ERR” cycling with “RUN” or “stop” Display depends on the level at which the voltage is out of specification . On OK display changes to “Vpsu”.	PSU outside the specified voltage range. See Note 1
Tx / Rx display “WRNG”	Incorrect key inserted.
Tx / Rx display “BADK”	Corrupt key (Replace Key)
Tx / Rx display “BLNK”	Rx frequency key has not been coded with any Tx code

Table 11 – Initial Configuration Routine Fault Indications

NOTE 1: *If there are multiple faults then the fault which occurs first will be displayed first. The additional errors will then be displayed in turn.*

7.2. Open Line Frequencies Setup : Set-up Routine

Step	Transmitter	Transmitter TU/ETU	Receiver TU/ETU	Receiver
0	Switch on the Tx PSU. Check that the Transmitter is configured and emitting signals. Display indicates "RUN" Check that the Output Module is set to step 1 and the resistor is set to 0R. **Note The Resistor shall remain in the 0R position and is not be used to adjust the output level levels**			Switch on the Rx PSU. Check that the receiver has been configured and is displaying 'NewK'. Confirm that the DC supply voltage is within the range 46V to 50V by use of the display (Vpsu) or a TTM/ETTCM.
1	Confirm that the DC supply voltage is within the range 46V to 50V by means of the display (Vpsu) or a TTM/ETTCM. Adjust the OM drive level as described in Rx column.	After completing adjustment of the OM step setting, check that the rail voltage at the Tx end, is not more than the maximum stated in Table 2. If the rail voltage cannot be set up, do not proceed until cause of error is corrected.		Adjust the OM drive level to achieve an Rx input current of 50mA on the receiver display (IAV). Long tracks might not achieve 50mA, but shall achieve more than 30mA. In the case of short feed cables and short track circuit length, Rx input current can be more than 50mA with an OM step setting of 1. In this case Rx input current should be less than 380mA. In the case of tracks with more than 1 Rx the set up should done monitoring the Rx on the longest section of track. See **Note 1** below.

Step	Transmitter	Transmitter TU/ETU	Receiver TU/ETU	Receiver
2a		If the Tx and/or Rx end of the track circuit is part of a mixed tuned zone, the set up shunt is fixed at 1.5Ω. Adjust a Shunt Box, to 1.5Ω, and connect it across the rail connections of the Rx end TU/ETU then proceed to step 4. Do not perform steps 2b, 3a and 3b. If not, proceed to step 2b.		
2b		Measure rail currents at Tx end (I_{1a} and I_{1b}) as shown in Section 7.3 - Open Line Frequencies Setup : Irail Determination and Calculation. Select the highest value (I_1) and discard the other.	Measure rail currents at Rx end (I_{2a} and I_{2b}) as shown in Section 7.3 - Open Line Frequencies Setup : Irail Determination and Calculation. Select the lowest value (I_2) and discard the other.	
3a			Calculate the I_{Rail} Ratio in % by dividing I_2 x 100 by I_1. Look up the value of ballast impedance in the Section 7.3 Table 11 to Table 13 (use the correct table for the frequency of the track circuit is used). If the set up shunt is given as 'Special', then follow the **special measures** process described immediately below Section 7.3 Table 14.	

Step	Transmitter	Transmitter TU/ETU	Receiver TU/ETU	Receiver
3b			Using the value of ballast impedance, look up the value of set up shunt in Section 7.3 Table 14. Adjust a Shunt Box, to the value of the set up shunt, and connect it across the rail connections of the Rx end TU/ETU.	
WARNING	**If the I_{Rail} ratio measurement requires the use of higher shunt values, and the track is not very wet, then this indicates that there is severe loss of current down the track which should be investigated and correct**			
4				Replace frequency key with a set-up key. Display will respond with 'SET?' Press the 'OK' button to begin the automatic set up process.

Step	Transmitter	Transmitter TU/ETU	Receiver TU/ETU	Receiver
5				Display will show the legend 'WAIT', followed by 'PASS' or 'FAIL'. 'PASS' indicates that set up has been successful, and the new threshold setting has been locked into the unit. 'FAIL' cycling with "X", where "X" is the error code, indicates that set up was unsuccessful. See Section 10 - Appendix H - Receiver Set Up Error codes for interpretation of the error code. Faults shall be corrected before another set up is attempted. See **Note 2** below.
6				Rx will display threshold level "Ith", followed by key frequency as"400X" where "X" = one of eight frequencies A to H, followed by "KEY S/N" for 1 second and "drop".
7			Remove Shunt Box.	Check that Receiver display shows 'Pick'
8a			Replace Shunt Box, set to 0.7Ω, across the rails	Check that Receiver display shows 'drop'
8b		Connect Shunt Box, set to 0.7Ω, across the rails		Check that Receiver display shows 'drop'
9			Remove Shunt Box	
10	Carry out a Full Test			

Step	Transmitter	Transmitter TU/ETU	Receiver TU/ETU	Receiver
11	Using the record cards – examples shown in Sections 18, 19 & 20 - record track clear current and threshold level current and drop shunt on the record card. Also carry out and record the additional measurements since these can be valuable fault-finding aids. Finally, verify that the clear track current is approximately twice the threshold. This validates that the correct drop shunt was used to set up the track.			

Table 12 – Open Line Frequencies Setup : Set-up Routine

NOTE 1: *If the clear track current is less than 30mA then the track circuit is losing current and the cause of the current loss shall be determined and rectified otherwise the safety margin of the circuit can be eroded.*

NOTE 2: *The set-up failure code consists of 4 letters which are designed to focus the fault investigation. Two examples are:*

- H indicates that the input signal is too high suggesting the OM step should be reduced.
- L indicates that the input signal is too low suggesting open circuits / poor connections, or a wrong frequency.

Examples of fault codes are given in Section 10.

7.3. Open Line Frequencies Setup : Irail Determination and Calculation

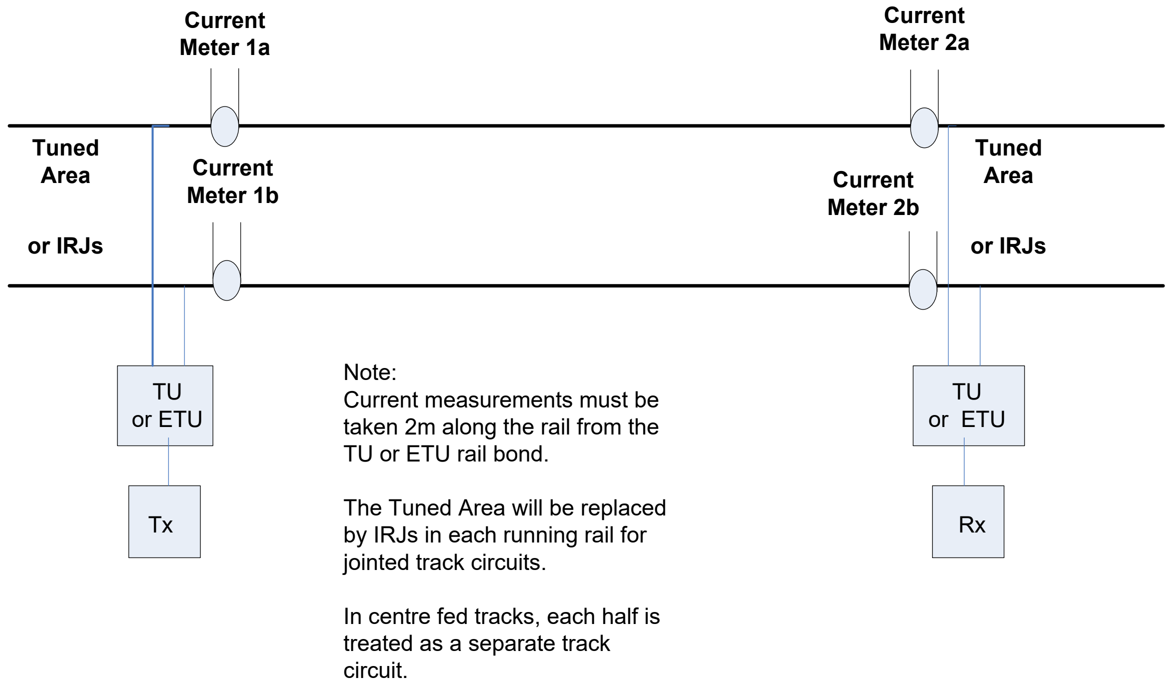

Figure 4 – Measurement Points for IRail Determination

7.3.1. Determination of Ballast Impedance from Irail ratio % for Various Track Lengths

When reading the Ballast Impedence from the Irail ratio %, the lower value shall be used. For example a 500m track length with a Irail ratio % of 77%, the Ballast Impedance is 3 Ωkm.

Track Length	**Frequencies A and E Ballast Impedance Ωkm**									
m	**2**	**3**	**4**	**5**	**6**	**8**	**10**	**15**	**20**	**200**

Table 16 – Set Up Shunt from Ballast Impedance for Various Track Lengths

Special Measures

If the set up shunt is given as 'Special' this indicates that the ballast is in a very poor condition. As an interim measure, until the ballast can be rectified, track circuits shall be set up at 3Ω. Affected track circuits shall be monitored weekly for increases in Rx clear track current (Inow on the Rx display). If Inow increases by more than 10% from the value at set up, then the track shall be re-set. If the ballast measurement of a track circuit in special measures does not return to normal levels and can be shown to be stable over several months, then a case can be made for reducing the set up shunt.

Example Set Up Shunt Determination

Frequency B track circuit, 757m long.
I1a = 1.012A   I1b = 1.023   Use 1.023A
I2a = 757mA   I2b = 782mA   Use 757mA
IRail Ratio = 757/1023 = 0.74 = 74%
Ballast (Table 12) = 8Ω (See Grey Cell – using the lower value)
Set Up Shunt (Table 16) = 1.2Ω (See Grey Cell)

8. Appendix F - Open Line Frequencies – Single Rail - Setup Configuration Routine

The Open Line commissioning procedure in Section 7 - Appendix E - Open Line Frequencies – Double Rail - Setup Configuration Routine can be used without alteration except that steps 0 and 1 of section 7.2 - Open Line Frequencies Setup : Set-up Routine is altered as shown below.

Step	Transmitter	Transmitter TU/ETU	Receiver TU/ETU	Receiver
0	Switch on the Tx PSU and confirm that the DC supply voltage is within the range 46V to 50V by means of the display (Vpsu) or a TTM/ETTCM. Display indicates "RUN" Check that the Output Module is set to step 1 and the resistor is set to 0R. **Note The Resistor shall remain in the 0R position and is not used to adjust the output level levels.**			Switch on the Rx PSU. Check that the receiver has been configured and is displaying 'NewK'. Confirm that the DC supply voltage is within the range 46V to 50V by use of the display or a TTM/ETTCM.
1	Adjust the OM drive level as described in Rx column	After completing adjustment of the OM step setting, check that the rail voltage at the Tx end, is not more than 2.3V. If the rail voltage cannot be set up, do not proceed until cause of		Adjust the OM drive level to achieve an Rx input current of 50mA on the receiver display (IAV). In the case of short feed cables and short track circuit length, Rx input current can be more than 50mA with an OM step setting of

Step	Transmitter	Transmitter TU/ETU	Receiver TU/ETU	Receiver
		error is corrected.		1. In this case Rx input current should be less than 380mA. In the case of tracks with more than 1 Rx, the set up should done monitoring the Rx on the longest section of track. See **Note 1** below.

Table 17 – Open Line Frequencies – Single Rail : Setup Configuration Routine

NOTE 1: *If the clear track current is less than 30mA then the track circuit is losing current and the cause of the current loss should be determined and rectified otherwise the safety margin of the circuit can be eroded.*

9. Appendix G – Station Area Frequencies – Setup Configuration Routine

9.1. Station Area Frequencies Setup : Initial Configuration

Step	Transmitter	Receiver
0	Transmitter with no key inserted. Transmitter key of the correct frequency available for use. This key contains a unique code for any market area. The key colour shall be the correct one for the market area - blue. With no key in place the display indicates "KEY?"	Receiver key starts off programmed for frequency only. The key colour shall be the correct one for the market area - blue. With no key in place the display indicates "KEY?" If an un-coded RX key is inserted in the Rx the Rx will respond with "BLNK"
1	The Output Module should be set to an initial drive level of 1. The resistor switch shall be set to 48R if the feed cable length is less than 750m, otherwise it shall be set to 0R position.	
2	Configuration process starts by inserting the Tx key in the Tx. This configures Tx for code and frequency. The display will first confirm key frequency as"400X" for 1 second where "X" = one of eight frequencies F1 to F8, followed by "KEY S/N" for 1 second and "RUN" when fully active and emitting signals.	
3	If Rx keys are required to be programmed, then remove Tx key. Display will again indicate "KEY?"	
4	Insert blank Rx key. The display will respond by indicating "CPY?" Press the "OK" pushbutton. Display responds "TxK?"	

Step	Transmitter	Receiver
	Remove Rx key and replace with Tx key. Display responds with “RxK?” Remove Tx key and replace with Rx key. After 1 second the display will change to “PASS” which indicates that the Rx key has been successfully programmed with the correct code.	
5	Repeat with subsequent Rx keys if multiple Rx used.	
6	Remove last Rx key and re-fit the Tx frequency key. The display will first confirm key frequency as”400X” for 1 second where “X” = one of eight frequencies F1 to F8, followed by “KEY S/N” for 1 second and “RUN” when fully active and emitting signals.	
7		Programmed Rx key inserted in Rx. The display will first confirm key frequency as”400X” for 1 second where “X” = one of eight frequencies F1 to F8, followed by “KEY S/N” for 1 second and “NewK” when fully active. Rx can display “drop” or “PICK” when fully active if the Rx key was programmed and used for the track circuit previously. Rx now active and ready for set up.
8		Perform the TC set up routine as per Section 9.2 - Station Area Frequencies : Track Circuit Set-up Routine.
Fault indications during the Initial Configuration Routine.		

Step	Transmitter	Receiver
If at any step of the initial configuration routine the Transmitter or Receiver displays differ from those indicated above then the table below shows the likely reasons.		
Note: Tx keys cannot be reprogrammed to a new code or frequency. Rx keys can be programmed to a new code, but cannot be reprogrammed to a new frequency.		

Table 18 – Station Area Frequencies Setup : Initial Configuration

Tx or Rx Display	Fault
Rx display “ERR” cycling with “drop” Tx display “ERR” cycling with “stop” On OK display changes to “STAT” On OK display changes to “INT”	Internal circuit fault with unit. See Note 1
Rx display “ERR” cycling with “PICK” or “drop” Tx display “ERR” cycling with “RUN” On OK display changes to ”TEMP”	Temperature has exceeded the temperature range -30°C to + 100°C. See Note 1
Rx display “ERR” cycling with “PICK” or “drop” Tx display “ERR” cycling with “RUN” or “stop” Display depends on the level at which the voltage is out of specification. On OK display changes to “Vpsu”	PSU outside the voltage range. See Note 1
Tx / Rx display “WRNG”	Incorrect key inserted.
Tx / Rx display “BADK”	Corrupt key (Replace Key)
Tx / Rx display “BLNK”	RX frequency key has not been coded with any TX code

Table 19 – Initial Configuration Routine Fault Indications

NOTE 1: *If there are multiple faults then the fault which occurs first will be displayed first. The additional errors will then be displayed in turn.*

9.2. Station Area Frequencies : Track Circuit Set-up Routine

Step	Transmitter	Transmitter TU/CU	Receiver TU/CU	Receiver
0	Transmitter configured and emitting signals. Display indicates "RUN". Confirm that the DC supply voltage is within the range 46V to 50V by use of the display or an MTM/ETTCM.			Receiver configured and displaying 'NewK'. Confirm that the DC supply voltage is within the range 46V to 50V by use of the display or an MTM/ETTCM.
1	Adjust the Output Module drive level to achieve an Rx input current of between 15 and 25mA while not exceeding 120W on the Tx output power 'Pout' reading[1]. The current should be set as close to 25mA as the 'Pout' and TU/CU voltage limit allows. If the track circuit is short, Rx input current may be more than 25mA with OM drive level 1. In this case RX input current should be less than 250mA.	Using a DVM/ETTCM on the AC range, check that the input voltage to the TU or CU does not exceed 95V RMS.		Read the Receiver current (IAV) on the Receiver display.

[1] Where these limits cannot be achieved, i.e. for long tracks and long Tx-to-track distances, the output power can be increased until 15mA is achieved, but a Tx end 0Ω shunt test must be carried out and the output power ('Pout') must be less than 180W with the shunt in place.

Step	Transmitter	Transmitter TU/CU	Receiver TU/CU	Receiver
	If the 48R resistor is in circuit, then than drive level must not exceed 13. Validate that the drive level does not exceed 13 by open circuiting the Output Module output (eg by opening the 6A track fuse) and checking that the output voltage is less than 95V.			
2		Measure the rail-to-rail voltage at the Tx tuning unit or coupling unit (pole). Using Table 3 - check that the correct rail voltage is obtained at the Tx end. If voltage is incorrect, do not proceed until cause of error is corrected. Typical causes are poor ballast, incorrect traction bonding, faulty impedance bonds (e.g. wrong tuning module for track frequency), or infrastructure faults.		
3		Measure the rail-to-rail voltage at		

Step	Transmitter	Transmitter TU/CU	Receiver TU/CU	Receiver
		companion tuning unit (zero) of the Tx tuned area. If the Tx is connected to a coupling unit or a mixed tuned zone omit this test. Divide the pole voltage (step 2) by this zero voltage (step 3) to determine the pole/zero ratio. Check that the ratio is in the correct range: 3 for F1, F3, F5 & F7. 5 for F2, F4, F6 & F8. If the ratio is lower than shown, then check that tuned area connections and the cable layout are in accordance with the installation drawings		
4			Using a shunt box, place a 1Ω shunt across the rails on the rail connections.	Replace the frequency key with a set-up key. Display will respond with 'SET?' Press the 'OK' button to begin the automatic set up process.
5				Display will show the legend 'WAIT',

Step	Transmitter	Transmitter TU/CU	Receiver TU/CU	Receiver
				followed by ‘PASS’ or ‘FAIL’. ‘PASS’ indicates that set up has been successful, and the new threshold setting has been locked into the unit. ‘FAIL’ cycling with “X”, where “X” is the error code, indicates that set up was unsuccessful. Faults must be corrected before set up is attempted again. See Note 1 below.
6				Replace set-up key with frequency key. Rx will display threshold level “Ith”, followed by key frequency as”400X” where “X” = one of eight frequencies F1 to F8, followed by “KEY S/N” for 1 second and “drop”.
7			Remove shunt box.	Check that Receiver display shows ‘PICK’ Verify that the clear track Rx input current is approximately 1.5 times the threshold level current (Ith). This validates that the correct drop shunt was used to set up the track.

Step	Transmitter	Transmitter TU/CU	Receiver TU/CU	Receiver
8			Connect a shunt box across the rails and determine the value at which the Receiver display shows 'drop' The shunt value must be ≥0.9Ω.	Check that Receiver display 'drop'
9			Remove shunt box	Check that Receiver display 'PICK'
10		Connect a shunt box across the rails and determine the value at which the Receiver display shows 'drop' The shunt value must be ≥0.9Ω.		Check that the Receiver displays 'drop'
11		Remove shunt box		Check that Receiver display shows 'PICK'
12a		Calculate Tx TZ Impedance as described in Test T. Tx TZ shall be more than 0.4Ω See Note 2 below		
12b			Calculate Rx TZ Impedance as described in Test U. Rx TZ Impedance shall be more than 0.4Ω.	

Step	Transmitter	Transmitter TU/CU	Receiver TU/CU	Receiver
			See Note 2 below.	
13	Set a shunt box to 0.2Ω and carry out a shunt test at the extremities of any points tracks which are not terminated by Receivers. In each case, ensure that the Track Relay drops and record the Rx input signal current			
14	Measure, and record, the supply voltage and current to the Transmitter and Receiver .*Use a suitable current clamp meter that has a 10A DC current range.*			
15	Using the record card in section 9, record the listed parameters on record card (see Note 2)			

Table 20 – Station Area Frequencies : Track Circuit Set-up Routine

NOTE 1: *The set-up failure code consists of 4 letters which are designed to focus the fault investigation. Two examples are:*

- H indicates that the input signal is too high suggesting that the OM setting should be reduced.
- L indicates that the input signal is too low suggesting open circuits / poor connections.

NOTE 2: *If the Tx end drop shunt or the TZ (Tuned Zone) impedance requirements are not met, then the TZ installation shall be thoroughly examined for compliance with the installation requirements. Rectification of installation deficiencies will correct these issues.*

10. Appendix H - Receiver Set Up Error codes

The automatic set-up failure code consists of 4 letters which are designed to focus the fault investigation:

- "H" indicates that the input signal is too high suggesting the Output Module is driving too much power.

- "L" indicates that the input signal is too low suggesting open circuits / poor connections.

Typical examples of fault codes are given in the following tables.

Typical Automatic Set-up Failure Codes

Message	Meaning of Code	Field Examples
C	Code does not match	Incorrect key or interference.
LC	Code does not match	Incorrect key or interference.
HC	Code does not match	Incorrect key or interference.
L	Input signal low.	Over-long TC. Poorly set-up tuned area. Loose connections.
H	Input signal high	TC too short.
HL	Input signal high and low	Internal Rx fault.
MSHL	All signals incorrect	Internal Rx fault.
Thld Tol	A-B mismatch between thresholds.	High level traction interference signal present.
Time Out	-	'OK' not pressed within 60 seconds.
Key Wrte	-	Faulty key or process corrupted.
WRNG	-	Set up key inserted before frequency key or incorrect frequency key inserted to finish the process.
BLNK		Rx frequency key has not been coded with any Tx code

Table 21 – Typical Automatic Set-up Failure Codes

11. Appendix I - Transmitter Operational Error Codes

Error Code	Quantity / Error Code	Test	Display	Mtce. Action Required
0	Internal Circuit Fault	Circuit monitoring tests failed. This test has highest priority	'ERR' cycling with 'RUN or stop' On 'OK' display routes to 'Stat' then 'OK' routes to 'INT'	Replace TX
1	Temperature	Error raised if the TFET is outside the range -30°C to +100°C *OR* The Transmitter is running *AND* the TTRN is outside the range -30°C to +100°C	'ERR' cycling with 'RUN' On 'OK' display routes to 'Temp'	Check Internal temperature of enclosure. If within temp. range then consider replacing TX
2	PSU Voltage	Error raised if PSU voltage outside the range 46V to 50V	'ERR' cycling with 'RUN or stop' On 'OK' display routes to 'Vpsu'	Check PSU setup.
3-8	Not used			
9	Power Up		Not an error as such, used to make a log entry.	Not an error code. Timestamp of last power up.
10-13	Not used			
14	Output Power	Error raised if Output Power exceeds 200W.	'ERR' cycling with 'RUN' On 'OK' display routes to 'Pout'	Check TX wiring, if no fault found check the OM3 is correctly set for tail cable length & track length. Otherwise change TX &/or OM3.
15	IR Comms Failure	Error raised if no comms with Output Module.	'ERR' cycling with 'RUN' On 'OK' display routes to 'Stat' then 'OK' routes to 'COMM'	Check the IR port between the TX and OM has not become obstructed. Otherwise change TX &/or OM3.

Error Code	Quantity / Error Code	Test	Display	Mtce. Action Required
17	Checksum	Error raised if config memory checksum error.	'ERR' cycling with 'PICK' or 'drop' On 'OK' display routes to 'Stat' then 'OK' routes to 'INT'	Replace TX
-	Corrupt Key	Corrupt key detected upon initial insertion.	BADK	Replace TX frequency key, copy the CODE to RX keys and carry out an Autoset
-	Assertion Error	Assertion Error occurs during normal operation	ErSW (Note: this error is not logged)	Replace the TX key as it could be a latent logging problem and cycle the unit's power. It will be necessary to copy the CODE to RX keys and carry out an Autoset If ErSW appears again replace the unit and carry out an Autoset.

Table 22 – Transmitter Operational Error Codes

These errors are not latched, i.e. if the quantity causing the error returns to normal, the 'ERR' display will be cleared and the fault relay energised. Note that the error is recorded in the error log.

The errors have a priority, 0 being the highest. If multiple errors exist then the only the highest priority error is shown. When it is cleared the next highest priority error is shown.

The last error generated will be stored and made available as one of the data items over the serial link.

12. Appendix J - Receiver Operational Error Codes

Error Code	Quantity / Error Code	Test	Display	Mtce. Action Required
0	Internal Circuit Fault	Circuit monitoring tests failed. This test has highest priority	‘ERR’ cycling with ‘PICK’ or ‘drop’ On pressing <OK> display routes to ‘Stat’ then pressing <OK> routes to ‘INT’	Replace digital RX
1	Temperature	Error raised if internal temperature outside the range -30°C to +100°C	‘ERR’ cycling with ‘PICK’ or ‘drop’ On <OK> display routes to ‘Temp’	Check Internal temperature of enclosure. If within temp. range then consider replacing digital RX
2	PSU Voltage	Error raised if PSU voltage outside the range +22V to +50V	‘ERR’ cycling with ‘PICK’ or ‘drop’ On <OK> display routes to ‘Vpsu’	Check PSU setup.
3	Not used			
4	Relay Voltage	Error raised if Relay Voltage below 10V and output is ON.	‘ERR’ cycling with ‘PICK’ On <OK> display routes to ‘Vout’	Check for a fault in the TR wiring, if no fault found change the Digital Rx
5	Relay State	Error raised if relay voltage > 10V and relay state = drop.	‘ERR’ cycling with ‘drop’ On <OK> display routes to ‘Vout’	Check for a fault in the TR wiring, if no fault found change the Digital Rx
6	Code Error	Error when QUAL < 90%	‘ERR’ cycling with ‘PICK’ or ‘drop’ On ‘OK’ display routes to ‘Stat’ then ‘OK’ routes to ‘CODE’	Check TC installation
7	Not used			

Error Code	Quantity / Error Code	Test	Display	Mtce. Action Required
8	Over-range Signal	Input current exceeds 500mA	'ERR' cycling with 'PICK' or 'drop' On <OK> display routes to 'Stat' then <OK> routes to 'OVR'	Check TC installation as this is not likely to be a digital RX fault. Check TU/ETU setting is on correct power mode.
9	Power Up			Not an error code. Timestamp of last power up.
10	Relay Power Trip	Relay power exceeds 6.25W	'ERR' cycling with 'drop' On <OK> display routes to 'Stat' then <OK> routes to 'TRIP'	Check TR wiring, if no fault found and TR is operating correctly, change the Digital RX.
11	FPGA Fail	One or both FPGA test flags are clear.	'ERR' cycling with 'drop' On <OK> display routes to 'Stat' then <OK> routes to 'INT'	Replace digital RX
12	Autoset	An Autoset has successfully occurred.		Not an error code. Time stamp of that last Autoset.
13	Relay Current	Error raised if Relay Current exceeds 260mA.	'ERR' cycling with 'PICK' or 'drop' On <OK> display routes to 'Pout'	Check TR wiring, if no fault found and TR is operating correctly, change the Digital RX.
17	Checksum	Error raised if config memory checksum error.	'ERR' cycling with 'PICK' or 'drop' On 'OK' display routes to 'Stat' then 'OK' routes to 'INT'	Replace digital RX
18	Logging fail	Error raised if logging has been disabled.	'ERR' cycling with 'PICK' or 'drop' On 'OK' display routes to 'Ekey'	Cycle the unit's power. If the Logging Fail error persists, Replace the RX

Error Code	Quantity / Error Code	Test	Display	Mtce. Action Required
None	Corrupt Key	Error raised if a corrupt key is detected upon initial insertion.	BADK	Replace frequency key and carry out an Autoset
None	Assertion error	An assertion error occurs during normal operation.	'ErSW' displayed (Note: this error is not logged).	Replace the key as it could be a latent logging problem and cycle the unit's power. If ErSW appears again replace the unit and carry out an Autoset.

Table 23 – Receiver Operational Error Codes

These errors are not latched, i.e. if the quantity causing the error returns to normal, the 'ERR' display will be cleared and the fault relay energised. Note that the error is recorded in the error log.

The errors have a priority, 0 being the highest. If multiple errors exist then the only the highest priority error is shown. When it is cleared the next highest priority error is shown. The last error generated will be stored and made available as one of the data items over the serial link.

13. Appendix K - Torque Settings

New or loose connections shall be Torqued to the install value defined in this Appendix. Where an existing connection is checked using the Check Torque value it is critical the fixing does not move when the Check Torque is applied.

Where a loose connection is identified or the fixing moves when checked to a "Check Torque" value; Slacken and check the components and then retighten to the Installation torque.

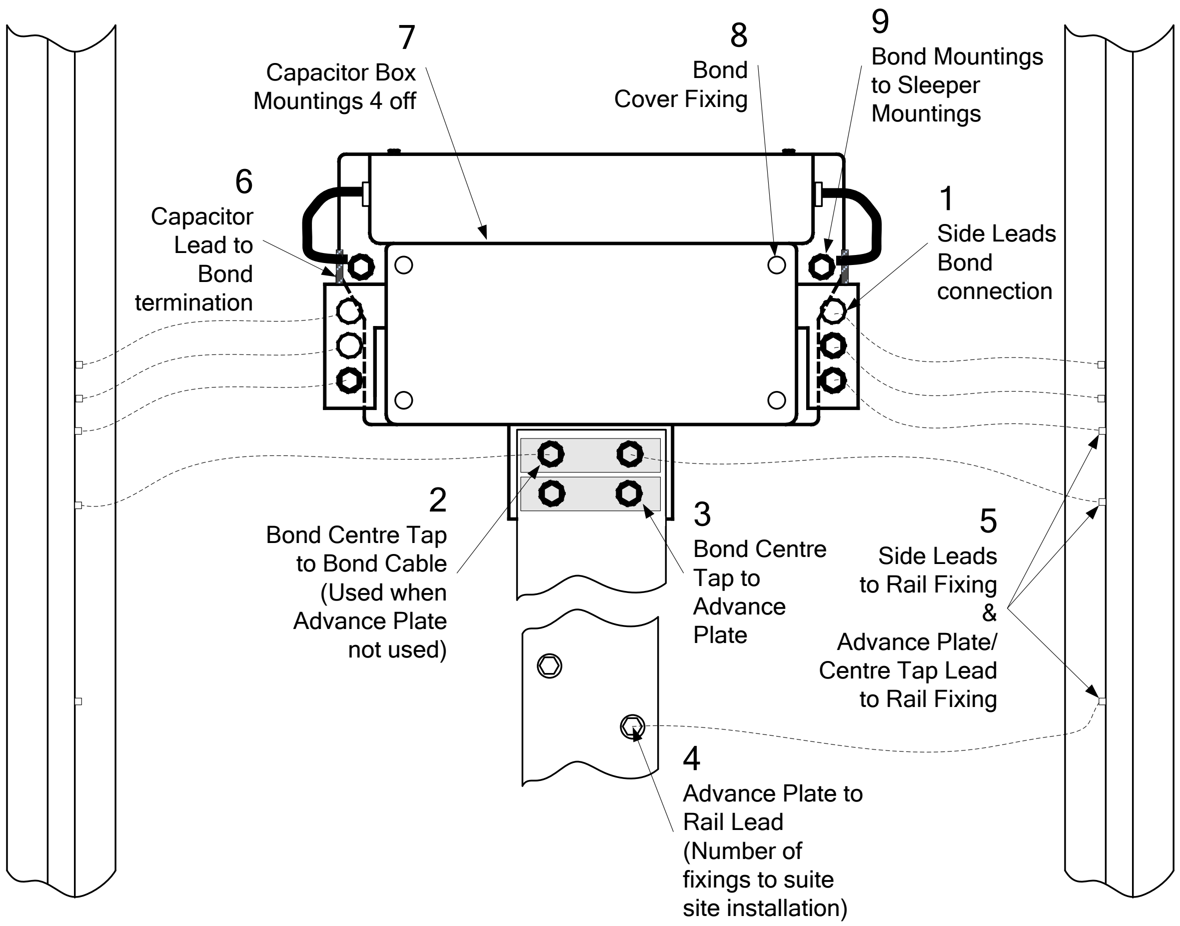

Figure 5 – Installation Positions requiring Torque settings

Equipment	Reference	Fixing Size	Torque Nm
Impedance Bond	Side Leads Bond connection (Copper crimps) Ref 1	M16	Install : 110 Check : 90
	Side Leads Bond connection (Aluminium crimps) Ref 1	M16	Install : 90 Check : 70
	Bond Centre Tap to Bond cable (Copper Crimp) Ref 2	M16	Install : 110 Check : 90
	Bond Centre Tap to Bond cable (Aluminium Crimp) Ref 2	M16	Install : 90 Check : 70
	Bond Centre Tap to Advance Plate (Aluminium) Ref 3 Note the correct installation procedure shall be used incorporating the spreader plates for all new installations.	M16	Install : 115 Check : 90
	Bond Centre Tap to Advance Plate (Aluminium) Ref 3 Non-Preferred Solution	M16	Install : 90 Check : 70
	Capacitor Box Mountings 4 off Ref 7	M6	7
	Capacitor Lead to Bond termination (Copper crimp) Ref 6	M10	Install : 35 Check : 25
	Advance Plate to Rail Lead Connection (Copper crimp) Ref 4	M16	Install : 90 Check : 70
	Advance Plate to Rail Lead Connection (Aluminium crimp) Ref 4	M16	Install : 90 Check : 70
	Advance Plate to Rail Lead Connection (Copper crimp) Ref 4	M12	Install : 72 Check : 60
	Advance Plate to Rail Lead Connection (Aluminium crimp) Ref 4	M12	Install : 72 Check : 60

Equipment	Reference	Fixing Size	Torque Nm
	Side Leads to Rail Fixing and Advance Plate / Centre Tap Leads to Rail Fixing (Copper crimp) Ref 5	M12 Uses Cembre or Glenaire rail fixings	Install : 72 Check : 60
	Side Leads to Rail Fixing and Advance Plate / Centre Tap Leads to Rail Fixing (Aluminium crimp) Ref 5	M12 Uses Cembre or Glenaire rail fixings	Install : 72 Check : 60
	Side Leads to Rail Fixing and Advance Plate / Centre Tap Leads to Rail Fixing (Copper crimp) Ref 5	Bolt	Install : 110 Check : 90
	Bond Cover Fixing (Uses lifting bolt holes) Ref 8	M10	Tighten manually using best judgement
Impedance Bond	Bond to concrete sleeper fixing including Bond Bottom Packing Covers. Ref 9	M16	110 Nm to fix bolt. 80 Nm to fix Bond #1
	Bond to timber sleeper fixing including Bond Bottom Packing Covers. Ref 9	M16 / $^5/_8$ inch coach screw with gimlet point.	60 #2
	Bond to steel sleeper including Bond Bottom Packing Covers. Ref 9	M12 Blind Bolt #3, Jam nut, Philidas nut	Jam Nut 17 Nm Philidas nut 50Nm
TU / ETU / SPETU	T1 & T2 (Copper crimp)	M10	Install : 25 Check : 20
	Rail connections (Cembre, Glenair or Hilti Stud, copper crimp)	M6	10
	Terminal block (Brass)	2BA (as supplied)	4.5 #4
	TU/ETU/SPETU to track mounted adapter plate or to mounting stake	M8 (as supplied)	24

Equipment	Reference	Fixing Size	Torque Nm
	Track mounted adapter plate to concrete sleeper (if used)	M16 Expanding bolt	120
	Track mounted adapter plate to timber sleeper (if used)	M16 / $^5/_8$ inch coach screw with gimlet point	60
	Track mounted adapter plate to steel sleeper (if used)	M10 Hilti stud	10
	Track mounted TU/ETU/SPETU protection cover.	M8	24
SATU / CU / Z Bond	T1 & T2 (Copper crimp)	M10	Install : 35 Check : 25
	Rail Connections (Cembre or Glenair, Copper Crimp)	M12 Rail Bonds	Install : 80 Check : 70
	Terminals Block	2BA	4.5 #4
	SATU/CU to Adaptor Plate / mounting unit or to mounting stake	2 x M8 min	24
	Adaptor plate to concrete sleeper (if used)	2 x M8 expanding or chemically locked bolt.	24
TX / OM / RX / PSU	Mounting	2BA / M5 (as supplied)	6 #4
LMU-TU	Terminals (Brass)	2BA	4.5 #4

Table 24 – Installation Torque Values

Traction Bonding connections are not covered in this table.

#1 M16 bolt or stud. Expanding metal sleeve type e.g. Expanding Hilti, RawlBolt.

Expanding bolt/stud shall be fixed to sleeper using following procedure:

- Fix bolt/stud to sleeper with torque of 110 Nm.
- Remove nut/washer, install bond/ Bond Bottom Packing Covers and replace with new Face Washer / Spring Washer / Full Depth Nut.
- Torque Full Depth Nut to 80 Nm.

#2 Use special M16 (5/8”) coach screws with gimlet point.
Intermediate Bond Cover bottom packing covers shall be installed between sleeper and Bond.

#3 Supplied by The Blind Bolt Company or accepted equivalent.

#4 If not able to torque, tighten manually using best judgement

14. Appendix L - EBI Track 400 Frequencies

Track	Open Line Track Circuits		Station Area Track Circuits	
	Frequency Identifier	Nominal Frequency	Frequency Identifier	Nominal Frequency
1	A	1699Hz	F1	6100Hz
	B	2296Hz	F2	7700Hz
2	C	1996Hz	F5	5700Hz
	D	2593Hz	F6	7300Hz
3	E	1549Hz	F3	6900Hz
	F	2146Hz	F4	8500Hz
4	G	1848Hz	F7	6500Hz
	H	2445Hz	F8	8100Hz

Table 25 – EBI Track 400 Frequencies

15. Appendix M - Impedance Bond Voltage Ratios

Impedance Bond Style	Voltage Ratio
DE	40:1
MR	56:1
P3	45:1
S	56:1
WH3	56:1
B3 500	Not applicable
B3 3000	Not applicable

Table 26 – Impedance Bond Voltage Ratios

16. Appendix N - EBI Track 400 B3 3000 Impedance Bond Information

Frequency	Capacitance µF	Tolerance
A	308.23µF	± 1.5%
B	167.22µF	± 1.5%
C	222.07µF	± 1.5%
D	130.79µF	± 1.5%
E	373.41µF	± 1.5%
F	191.80µF	± 1.5%
G	259.76µF	± 1.5%
H	147.29µF	± 1.5%
F1	23.90µF	± 1.5%
F2	15.00µF	± 1.5%
F3	18.70µF	± 1.5%
F4	12.30µF	± 1.5%
F5	27.40µF	± 1.5%
F6	16.70µF	± 1.5%
F7	21.00µF	± 1.5%
F8	13.50µF	± 1.5%

Table 27 – Capacitor Box capacitance values

The Inductor in the Impedance Bond should be between 27.8µH – 28.2µH

17. Appendix O - EBI Track 400 Mixed Tuned Zone : Open Line Tuned Area Capacitor values

Frequency	Capacitance µF
A	129.6 – 133.6 µF
B	70.8 – 73.0 µF
C	90.7 – 93.5 µF
D	61.1 – 63.0 µF
E	150.8 – 155.6 µF
F	79.3 – 81.9 µF
G	106.1 – 109.3 µF
H	62.4 – 64.4 µF

Table 28 – Mixed Tuned Zone Open Line Tuned Area Capacitor values

18. Appendix P - An alternative method for setting up the track circuit after a failed Transmitter, LMU-TU, OM or TU/ETU/SPETU/SATU/CU

The SM(S) should risk assess the ability to gain safe site access and the competence of Maintenance staff attending the track circuit equipment and should satisfy themselves that the use of the procedure is appropriate and authorise its use.

A full test shall be carried out as soon as practicable.

Deferral of testing, up to a limit of 48 hours, can be permitted on the basis of safety if this setup procedure is used.

1. Remove the faulty unit and replace with the new one.

   For an OM this shall be installed with the same settings as the failed unit. The settings shall also match the last settings on the record card. If they do not proceed to Step 8.

2. Note the clear track and threshold current values recorded on the track circuit record card.
3. Check that the threshold value on the receiver (Ith) is the same as that entered on the record card.

   For track circuits with multiple receivers, all thresholds shall be checked.
   If the thresholds have changed then proceed to Step 8.

4. Check that the clear track current is within ±10% of the original value.

   If the clear track current is not within ±10% of the original value proceed to Step 6 unless track access is not available to perform drop shunt testing, in which case proceed to Step 8.

   If the clear track current is not within ±20% of the original value proceed to Step 8.

5. Fill in the record card noting alternative setup procedure used. Set up completed. Do not carry out steps 6, 7 or 8.
6. Check that all receivers drop with 0.8Ω across their rail connections, and that 0.8Ω at the transmitter rail connections drops all receivers in the track circuit. If the drop shunt tests fail proceed to Step 8.

7. Complete the record card noting alternative setup procedure used.

   The setup has been completed. Do not proceed to Step 8.

8. The criteria for using this alternative set up procedure have not been met. A Full Test shall be performed before the equipment is handed back.

19. Appendix Q - An alternative method for setting up the Receiver after a Failed Transmitter Key, Failed Reciever or Failed Reciever Key

The SM(S) should risk assess the ability to gain safe site access and the competence of Maintenance staff attending the track circuit equipment and should satisfy themselves that the use of the procedure is appropriate and authorise its use.

A full test shall be carried out as soon as practicable.

Deferral of testing, up to a limit of 48 hours, may be permitted on the basis of safety if this setup procedure is used.

This procedure is to be completed regardless of whether the unit has been previously used or not.

1. If the Transmitter (TX) Key is not being replaced, start at Step 2.

   Replace the TX Key. The Reciever(RX) Key will now need to be programmed to the new TX Key. Refer to the initial configuration in this appendix for instructions to complete this and return here to complete the test.

   NOTE: If the track has multiple RXs then each RX Key needs to be re-coded.

   If the TX Key has been replaced and Step 1 completed, go to Step 4.

2. Power up the Receiver. The display will respond with ‘KEY?’.

3. Fit the correct frequency key for the track circuit under test.

   The display will echo back the frequency in the format, for example ‘400A’ for frequency A, and then display the relay state (‘PICK’ or ‘drop’) or ‘NewK’.

4. Confirm that the RX has a supply voltage within the range 47V to 49V.

5. Check the *Inow AV* current displayed on the RX.

   Note this value.

6. Using the Average Current value (*Inow AV*) from the test above, confirm that it is the same as recorded on the track record card or within ±10% of that value.

   If the clear track current is more than ±10% outside the required level, or is fluctuating by more than 5mA. This indicates that the track circuit is losing current and is not a receiver problem.

   In this case the cause of the current loss should be determined and rectified otherwise the safety margin of the circuit can be eroded.

   NOTE: *Items such as Ballast or Equipment degradation and Environmental Conditions (Temperature Extremes, Heavy Rainfall) etc. should all be considered.*

   Variations are permitted under exceptional circumstances depending on ballast and environmental conditions.

7. Using the 2mm test lead adaptors, attach a Shunt Box across the IPC and IP1 (Open Line) or IPC and IP2(Station Area) terminals, or at the equivalent point on the surge arrestor terminals.

   Adjust the shunt resistance so that the average track current reads as close as possible to the threshold current value recorded on the test record card.

8. Leaving the Shunt Box in place, remove the frequency key and replace it with the set-up key.

   The display will respond with 'SET?'.

   Press the 'OK' button to begin the automatic set-up process.

   The condition monitoring display will show the legend 'WAIT', followed by 'PASS' or 'FAIL'.

   'PASS' indicates that set-up has been successful, and the new gain settings have been locked into the unit.

   'FAIL' indicates that set-up was unsuccessful.

9. In the case of 'FAIL', the display will cycle with the reason for failure shown as a code. The track circuit shall be investigated, and any faults corrected before the set-up is attempted again.

10. Leaving the shunt box applied. Remove the set-up key and replace with the frequency key. Confirm that the INOW AV current is the same as Step 7.

    If not, then the set-up procedure needs to be repeated.

11. If Step 10 passes then remove the shunt and confirm that the track relay picks.

12. Check that the clear track current is within ±10% of the original value. If this is the case, then proceed to Step 13.

    If the clear track current is more than ±10% of the original value a Full Test is required.

13. Check the Inow QUAL is 100%.

    If it is not, this shall be investigated and corrected and the process re-started from Step 5.

14. Check that all receivers drop with 0.8Ω across their connections which go out to the rails, and that 0.8 Ω at the transmitter connections which go out to the rails, drops all receivers in the track circuit.

    If the drop shunt tests pass, then proceed to Step 15.

15. Record all values as required on the track record card, noting the alternative setup used.

16. Where there are multiple RXs and a TX Key has been replaced, repeat Steps 4 to 15 for each RX.

END

Introduction

This appendix contains additional information relating to the Westlock Interlocking system. It contains the following sections:

1. Westlock and WTS Healthy Indicators.
2. Periodic Task 01.
3. Periodic Task 02.
4. Periodic Task 03.
5. Equipment Replacement Processes.

1. WESTLOCK and WTS Healthy Indicators

Technicians' Workstation or Control System Gateway (where fitted) Compact PCI based equipment.

The System `healthy' indicators are illuminated as shown as follows:

Card	Indication	Status
Processor Card	Run LED	Green steady
PMC Card	Power LED	Green steady
PSUs	Status LED	Green steady

<u>WESTLOCK Cubicle</u>

The **CIP** system 'healthy' indicators are illuminated as shown as follows:

Unit	Indication	Normal State
MP modules	Pass	Green steady
	Fault	Off
	Active	Green flashing
CM modules	Pass	Green steady
	Fault	Off
	Active	Green steady
DI modules	Pass	Green steady
	Fault	Off
	Active	Green steady if on- line, off if on standby
	Field Power	Off

The **TIF** system `healthy' indicators are illuminated as shown as follows:

Unit	Indication	Normal State
MP modules	Pass	Green steady
	Fault	Off
	Active	Green flashing
CM modules	Pass	Green steady
	Fault	Off
	Active	Green steady
SCM modules	Pass	Green steady
	Fault	Off
	Active	Green steady
	Ext Alarm	Off
DLM	Power	Red steady
LDT	Power	Red steady
	System	Red steady
	PCM Tx Clock	Red steady
	PCM Rx Clock	Red steady
	PCM Rx Line	Red steady
	Data From SSI	Red steady
	Data To SSI	Red steady
	Data To PCM	Red steady

NOTE: *Depending on which variant the TIF is, it is fitted with either DLMs or LDTs.*

The **FEP** system `healthy' indicators are illuminated as follows:

Indication	Active PM	Inactive PM
24V	Green steady	Green steady
Active	Green flashing	Off
Standby OK	Green steady	Green steady
Fault	Off	Off
Alphanumeric Display	Off	Off
SMB A, B, C & D	Off (not used)	Off (not used)
Processor A Run	Green flashing	Green flashing
Processor B Run	Green flashing	Green flashing
Processor D Run	Green flashing	Green flashing
Processor A Ready	Green steady	Green steady
Processor B Ready	Green steady	Green steady
Processor D Ready	Off (not used)	Off (not used)
Processor A PM-PM	Green steady	Green steady
Processor B PM-PM	Green steady	Green steady
Processor A PM-PM	Yellow flashing	Yellow flashing
Processor B PM-PM	Yellow flashing	Yellow flashing
Ethernet A Link	Green steady	Green steady
Ethernet B Link	Green steady	Green steady
Ethernet A Activity	Yellow flashing	Yellow flashing
Ethernet B Activity	Yellow flashing	Yellow flashing

The shared **Ethernet and Power Supply** ‘healthy’ indicators are illuminated as follows. For single CIP or TIF cubicles these are:

Unit	Indication	Normal State
Ethernet Switches	DC1	Green steady
	DC2	Green steady
	ON	Green steady
	1 to 8	Flash (used ports only) to show
PSUs	DC-ON	Green steady

For Du**al Cubicles (managed)** these are:

Unit	Indication	Normal State
Ethernet Switches	DC-A	Green steady
	DC-B	Green steady
	SYS	Green steady
	Ports	Flash (used ports only) to show
PSUs	DC-ON	Green steady

For **Dual Cubicles (unmanaged)** these are:

Unit	Indication	Normal State
Ethernet Switches	PWR1	Green steady
	PWR2	Green steady

The **RSA** system 'healthy' indicators are illuminated as follows:

Indication	RSA A	RSA B
24V	Green steady	Green steady
Active	Green flashing	Green flashing
Fault	Off	Off
Alphanumeric Display	Off	Off
SMB A	Green flashing	Off (not used)
SMB B	Off (not used)	Green flashing
SMB C & D	Off (not used)	Off (not used)
Ethernet A Link	Green steady	Green steady
Ethernet B Link	Green steady	Green steady
Ethernet A Activity	Yellow flashing	Off (not used)
Ethernet B Activity	Off (not used)	Yellow flashing

The **SOM110** system 'healthy' indicators are illuminated as follows:

Common Indications	State
24V	Green steady
Fault	Off
SMB A	Green flashing
SMB B	Green flashing

The state of other indications on each SOM110 might vary with the state of the railway.

2. Periodic Task 1

2 Year Maintenance - TF or CSG (where fitted) BlueChip PC based equipment

BlueChip PC based TFs and CSGs - Replacing a Lithium Battery

Removal

1. Isolate the power from the PC.
2. Unscrew the thumb screw on the front of the PC and lower the access door.
3. Unscrew the two thumb screws securing the fan assembly and carefully pull the fan assembly clear of the PC casing, see Figure 1.
4. Carefully pull the battery holder out of the retaining clip.
5. Remove the old battery.

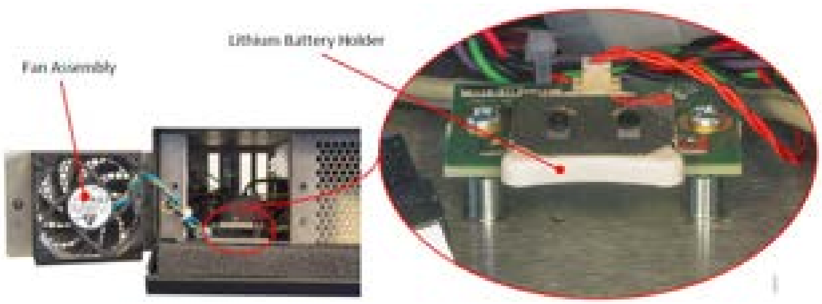

Figure 1 – Lithium Battery Location

Replacement

1. Check the new battery is the same type as the one removed.
2. Insert the new battery, + side up into the holder.
3. Carefully insert the holder into the retaining clip, see Figure 2.

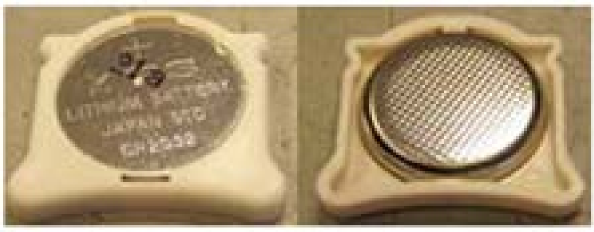

Figure 2 – Lithium Battery Holder

4. Insert the fan into the PC and secure with the two thumb screws.
5. Close the access door and secure using the thumb screw.
6. Reapply power to the PC.
7. Reset the BIOS as detailed below.

Setting TF BIOS

When a TF-S or TF-R PC is replaced, or the lithium battery is replaced the PC's BIOS shall be set as follows:

1. Reset to Default Setting

To set the BIOS to the default settings.

a) During boot-up, press the <Delete> key to enter the BIOS menu.

b) Press the <F3> key to select Optimal Defaults and select the OK.

c) On main screen set Date and Time.

2. Power On Self-Test/Power Button Configuration

To set the PC to perform a full range of self-tests when powered up, to enable the BIOS output to be visible on the console and to configure the power button to perform a delayed power down.

a) Select the Advanced tab.

b) Select Boot Feature.

c) Set value of Quiet Boot to Disabled.

d) Set Value of Power Button Function to 4 Seconds Override.

e) Press the <Esc> key to return to the main BIOS screen.

3. Disable Intel AMT

The Intel AMT technology is disabled on the PC motherboard. To prevent hardware conflicts the AMT shall be disabled in the BIOS as follows:

a) Select the Advanced tab.

b) Select AMT Configuration.

c) Set value of AMT Support to Disabled.

d) Press the <Esc> key to return to the main BIOS screen.

4. Enable All Graphic Adaptors

All graphic adaptors fitted shall be enabled as follows:

a) Select the Advanced tab.

b) Select Chipset Configuration.

c) Select System Agent Configuration.

d) Set value of Initial Graphic Adaptor to IGD.

e) Set value of IGD Multi-Monitor to Enable.

f) Press the <Esc> key twice to return to the main BIOS screen.

5. Set SATA to Windows Mode

__NOTE:__ Windows does not configure itself to load the AHCI driver upon boot if the SATA-drive controller was in IDE mode and not in AHCI mode at the time of OS installation. So, the PC does not boot up if the SATA controller is later switched to AHCI mode or the OS image was installed in IDE mode. The drive controller should be changed to AHCI before installing the operating system".

The SATA Mode shall be set to operate with Windows as follows:

a) Select the Advanced tab.

b) Select IDE/SATA Configuration.

c) Set value of SATA Mode to IDE Mode or AHCI Mode.

d) Press the <Esc> key to return to the main BIOS screen.

6. Super I/O Configurations

As Port 3 and Port 4 are not used, these ports need to be disabled as follows:

a) Select the Advanced tab.

b) Select Super I/O Configuration.

c) Set value of Serial Port 3 to Disabled.

d) Set value of Serial Port 4 to Disabled.

e) Press the <Esc> key to return to the main BIOS screen.

7. Boot Option Priority

Configure the PC to boot off the correct drive as follows:

a) Select Boot tab.

b) Select Boot Options Priority.

c) Set value of Boot Option 1 to STAT: WDC xxxxxxxxxx (see note below).

d) Set value of Boot Option 2 to Disabled.

e) Press the <F4> key to save and exit, the PC continues to boot.

3. Periodic Task 2

10 Year Maintenance - TW or CSG (where fitted) Compact PCI based equipment

Failure to replace the battery periodically can result in the loss of BIOS parameters in the event of a computer black start. This results in increased start up time due to loss of BIOS parameters and can also cause reduced or incorrect operation while operating.

1. To replace a RAM battery:

   a) Re-boot computer and press F2 to enter BIOS Setup when prompted on VDU.

   b) Using the arrow keys and the help menu to navigate the screens and menu items, note all parameters for all menu items on all screens.

   c) Remove Processor module.

   d) Replace coin cell BR 2032 and check correct polarity.

   e) Replace Processor module.

   f) Turn on computer power and press F2 when prompted on the VDU to enter BIOS set up.

   g) Check all screens and menu items are set as noted in step 3 above.

   h) When BIOS set up complete, Press F4 to save and exit BIOS set up.

   i) Select 'Yes' to confirm BIOS settings on the confirmation screen.

The computer now reboots, load and run the program without further operator intervention.

It is recommended to prolong battery life that batteries are only fitted to spare modules immediately prior to being put into service. The shelf life of a battery in its original packing is in excess of 10 years. When fitted it is considerably shorter.

4. Periodic Task 3

14 Year Maintenance - WESTLOCK CIP and TIF Main Processors

The CIP, TIF and SIF Main Processors (MPs) contain a Lithium battery which shall be replaced periodically to maintain the MP's backup memory. Each MP has a label showing the date of manufacture; use this information to calculate service date. The format of the serial number is shown as yy.ww.nnnn, where yy is the year and ww is the week of manufacturer.

All MPs held as spares shall be serviced as above.

To prevent any interruption to service, it is recommended to replace only one MP at a time with a serviceable spare.

These batteries are not user serviceable, and the MP shall be returned to the factory for servicing, including all spares.

5. Equipment Replacement Processes

5.1 Replace a WESTLOCK Interlocking Module

a) On the WESTLOCK module to be removed, rotate the Lock lever counter clockwise through 270° until the module ejects from the baseplate.

b) Insert the replacement WESTLOCK module with the lock lever in the 6 o'clock position and rotate the lock lever clockwise to draw the module into the baseplate.

c) Continue rotating the Lock lever until it is in the 3 o'clock position. This might require firm pressure.

d) Check the lock indicator (red LED) is Off. If the indicator is on, the module is incorrectly seated.

5.2 Replace a WESTLOCK Ethernet Switch

a) Remove the input supply from the switch by unplugging the screw terminal block from the top of the switch.

b) Note the positions of the data cables connected to the switch ports. Check the cables and wires are correctly labelled.

c) Unplug the data cables from the switch ports.

d) Unclip the switch from the DIN rail and label it.

e) Fit the replacement switch onto the DIN rail.

f) Connect the cables to the switch ports in the positions noted at c.

g) Plug the input supply screw terminal into the socket on the top plate of the switch.

h) On the front panel of the switch, check that DC1, DC2 and On LEDs are lit.

i) After a short pause, check the port activity indicators begin flashing (used ports only).

j) At the TW(L), check the fault list to confirm correct operation of the network.

5.3 Replace a WESTLOCK Power Supply Unit (PSU)

a) Positively identify the power supply unit to be removed. The front panel of the PSU has a DC on status indicator, lit when the output is present.

NOTE: *If one power supply unit is faulty, powering down the remaining PSU removes the DC supply from the cubicle equipment.*

b) Positively identify the input and output power fuses for the PSU to be removed.

c) Remove the fuses and check on the PSU input terminals that the 110V AC is absent.

d) Note the positions of the input and output wires on the PSU terminals. Check the cables and wires are correctly labelled.

e) Remove the wires from the PSU terminals, insulating them using insulating tape.

f) Remove the PSU from the DIN rail and label it.

g) Fit the serviceable replacement PSU onto the DIN rail, in the same position as the original PSU.

h) Connect the input and output wires in the positions noted at step d. If in doubt, refer to the site records.

i) Re-fit the fuses removed at step b.

j) On the front panel of the PSU, check the DC On status indicator is lit.

k) At the TW(L), check the fault list to confirm correct operation of the PSU.

5.4 Replace a WESTLOCK CSG or TW(L) Module

a) At the rear of the housing, set the input power switches for both PSUs to the off (O) position.

b) Disconnect any data cables from the card.

c) Undo the single securing screw at the left and right of the card.

d) Release the card from the backplane connector by pressing the left and right card handles apart.

e) Carefully slide the card from the housing and place it in an anti-static bag.

f) At the rear of the housing, set the power input switch supplying the failed PSU to the off (O) position.

g) At the front of the housing, undo the screws securing the PSU to the housing and remove the PSU.

h) Isolate power to the KVM by disconnecting the mains cable feeding the KVM power supply. Check cables are correctly labelled.

i) Disconnect the connectors from the rear of the KVM unit.

j) Unscrew the four screws securing the KVM to the rack and withdraw the complete KVM.

k) Check the replacement card is correct type (the same type as the one removed and has been supplied by WRSL specifically for this type of installation).

l) Insert the card into its correct position and secure using the two front panel screws.

m) Reconnect the data cables as necessary, check each cable is fitted into the correct connector. If in doubt, refer to the site records.

n) Set the input power switches to on (I). Wait for the processor to boot up.

o) If the replaced card was a Rear Transition Module (which contains the hard disk drive), load the operating program.

p) Only competent personnel shall perform this task by inserting a USB memory stick containing the correct version and application, then selecting the application (TW(L), CSG ‘A’ or CSG ‘B’) using the keyboard/VDU field (input) fault and a module fault, resolve the field fault first.

q) Check all indications are correct and the equipment works correctly.

r) Check the replacement PSU is correct type (the same type as that removed).

s) Check the PSU is the correct way up, and then carefully align the PSU with the guides within the housing before sliding the PSU fully into the housing.

t) Apply firm pressure on the PSU front panel to fully insert the PSU into the housing.

u) Secure the PSU with the front panel screws.

v) Restore the mains input supply and check the Status indicator on the front panel illuminates.

w) Check that the replacement KVM unit is correct type (the same type as the one removed).

x) Slide the KVM housing into the rack and secure with the four screws.

y) Reconnect the cables at the rear of the KVM housing.

z) Restore power to the KVM.

aa) Test for correct operation.

5.5 Replace a WESTLOCK Baseplate

a) At the baseplate to be replaced, remove the modules. For each module, rotate the lock lever counterclockwise through 270° until the module ejects from the baseplate.

b) Disconnect any cables or wires from the baseplate. Note that on the DI baseplate the complete connector might be unplugged.

c) At the top and bottom of the baseplate to be removed, identify the crosshead screws securing the interconnect assemblies (4 screws) or cover assembly (2 screws) to the baseplate. Undo the securing screws and remove the interconnect / cover assemblies.

d) Undo and remove the four crosshead screws and associated lock washers securing the baseplate to the rear panel of the cubicle. Retain the screws and washers.

e) Carefully withdraw the baseplate from the cubicle.

f) Remove the address plug from the baseplate and plug it into the replacement baseplate.

g) Check the replacement baseplate is correct type (same type as the one removed and has been supplied by WRSL).

h) Fit the replacement baseplate into its correct position and secure using the four crosshead screws and associated lock washers.

i) Visually Check the interconnect assemblies for damaged connector pins. If damaged pins are present, replace the interconnect assembly.

j) Fit the interconnect assemblies / cover assembly and secure by tightening the four crosshead screws (interconnect assembly) or two crosshead screws (cover assembly).

k) Reconnect the cables or wires as necessary, check each cable is fitted into the correct connector. If in doubt, refer to the site records.

l) Insert each module into the baseplate with the lock lever in the 6 o'clock position and rotate the lock lever clockwise to draw the module into the baseplate. Continue rotating the lock lever until it is in the 3 o'clock position. This might require firm pressure.

5.6 Removal of CIP or TIF Module

a) If CIP or TIF module is to be removed, rotate the Lock lever counterclockwise through 270° until the module ejects from the baseplate (it is recommended to use a screwdriver).

b) Insert the replacement CIP or TIF module with the lock lever in the 6 o'clock position and rotate the lock lever clockwise to draw the module into the baseplate.

c) Continue rotating the Lock lever until it is in the 3 o'clock position. This might require firm pressure (it is recommended to use screwdriver).

d) Check the lock indicator (red LED) is Off. If the indicator is on, the module is incorrectly seated.

Removal of an PM from a FEP

a) Loosen the captive lock screw in each handle at the top and bottom of the module.

b) Press the red button in the lower handle. This shuts down the module and releases the lower handle.

c) Wait one second after depressing the red button to allow the module to shut down. This prevents damage to module components and proves the integrity of the backplane supply voltage during removal.

d) Swing both handles outwards to release the module and slide the module out of the housing along its guides.

e) Align the rails on the left top and bottom edge of the replacement module with the tracks at the top and bottom of the slot.

f) Push the module in until the levers start to engage.

g) Do not use excessive force: it's possible to bend terminals or break polarising pegs if the connectors and sockets are misaligned, or if the module is of the wrong type.

h) Pull up on the bottom lever and press down on the top lever at the same time to ease the module into the backplane, until the red power switch in the bottom lever clicks into place.

i) Tighten captive screws.

5.7 Replacing Westermo Lynx L106 and Cisco IE2000 and Amplicon EX43008-00-1-A

a) Power down the affected Ethernet switch by opening the fuse carriers on the power distribution rail. Note that there are two power supplies to each switch.

b) Unplug the screw terminal connector block or blocks from the switch. (Westermo Lynx L106 switches have one connector block. Cisco IE2000 switches have two connector blocks, one for each power supply).

c) Note the positions of the cables before unplugging from the switch ports.

d) Unclip the switch from the DIN rail by pulling down on the movable tab at the bottom of the unit then label it.

e) Fit the replacement switch onto the DIN rail.

f) Connect the cables to the switch ports in the positions noted at Step c).

g) Plug the input supply screw terminal connector block(s) into the switch.

5.8 Replace MP, CM, DI and SCM Baseplates

a) At the baseplate to be replaced, remove the modules. For each module, rotate the lock lever counterclockwise through 270° until the module ejects from the baseplate.

b) Disconnect any cables or wires from the baseplate. Note that on the DI baseplate the complete connector might be unplugged.

c) At the top and bottom of the baseplate to be removed, identify the crosshead screws securing the interconnect assemblies (4 screws) or cover assembly (2 screws) to the baseplate. Undo the securing screws and remove the interconnect / cover assemblies.

d) Undo and remove the four crosshead screws and associated lock washers securing the baseplate to the rear panel of the cubicle. Retain the screws and washers.

e) Carefully withdraw the baseplate from the cubicle.

f) Remove the address plug from the baseplate and plug it into the replacement baseplate.

g) Fit the replacement baseplate into its correct position and secure using the four crosshead screws and associated lock washers removed at Step c).

h) Visually check the interconnect assemblies (removed at step b) for damaged connector pins. If damaged pins are present, replace the interconnect assembly.

i) Fit the interconnect assemblies / cover assembly removed at Step b). and secure by tightening the four crosshead screws (interconnect assembly) or two crosshead screws (cover assembly).

j) Reconnect the cables or wires as necessary.

k) Insert each module into the baseplate with the lock lever in the 6 o'clock position and rotate the lock lever clockwise to draw the module into the baseplate. Continue rotating the lock lever until it is in the 3 o'clock position. This might require firm pressure.

5.9 Replace a WESTLOCK FEP Housing Backplane

a) Remove the two PMs from the FEP housing following the procedure in NR/SMTH/Part04/WL01 (Replace a WESTLOCK Interlocking Module).

b) Disconnect the four Ethernet cables and two power connections from the front panel of the FEP housing.

c) Disconnect the earth strap connecting the housing to the rear panel of the cubicle.

d) On each side of the FEP housing to be removed, identify and remove the crosshead screws securing the housing to the rear panel of the cubicle. Retain the screws and washers.

e) Carefully withdraw the housing from the cubicle.

f) Remove the panel in front of the Addressing Plug from the front of the housing to improve access to the Addressing Plug.

g) Remove the seals covering the Addressing Plug retaining screws, release the two screws and pull the Addressing Plug forward and out of the housing.

h) Disconnect the power connectors from the connections labelled 24V-A and 24V-B on the rear of the housing.

i) Remove the six SMB terminators from the SMB connections on the rear of the housing.

j) Remove and retain the six screws from the top and bottom of the cover plate and remove the cover.

k) Carefully mark the position of the backplane on the housing to check the connectors on replacement backplane align correctly with the rails supporting the processor modules.

l) Remove and retain the remaining four screws holding the backplane on to the housing and remove the backplane.

m) Align the backplane to the alignment marks made.

n) Note the position of the four slots in the protective cover and attach the backplane to the housing using the screws removed at Step j) so that the screws align with the slots in the protective cover.

o) Fit the protective cover plate using the six screws removed.

p) Re-fit the six SMB terminators to the SMB connectors.

q) Visually check cables for damaged connector pins. If necessary, replace the cable with a serviceable spare.

r) Reconnect the power connections.

s) Check wiring and cables are replaced as labelled.

t) WIRE COUNT replacement unit to diagram.

u) Fit the Addressing Plug removed from the failed backplane into the replacement backplane and secure it using the retained fixings.

v) Fit new red seals covering the retaining screws on the Addressing Plug.

w) Place the removed backplane in the transit packaging and return it to Siemens Rail Automation for repair.

x) Fit the housing into its correct position and secure using the four crosshead screws and associated lock washers removed.

y) Visually check cables for damaged connector pins. If damaged pins are present, replace the cable with a serviceable spare.

z) Reconnect the Ethernet cables and power connections, checking each cable is fitted into the correct connector.

aa) Insert each Processor Module (PM) into the housing following the procedure in NR/SMTH/Part04/WL01 (Replace a WESTLOCK Interlocking Module).

5.10 Replace a Siemens Zone Controller module

a) Loosen the captive lock screw in each handle at the top and bottom of the module.

b) Press the red button in the lower handle. This shuts down the module and releases the lower handle.

c) Wait one second after depressing the red button to allow the module to shut down. This prevents damage to module components and maintains the integrity of the backplane supply voltage during removal.

d) If the module to be replaced is a MAU, disconnect the optical fibre connections from the front of the MAU taking care to protect the ends.

e) Swing the handles outwards to release the module and slide the module out of the housing along its guides.

f) Align the rails on the left top and bottom edge of the module with the tracks at the top and bottom of the slot.

g) Push the module in until the levers start to engage.

h) Do not use excessive force: it’s possible to bend terminals or break polarising pegs if the connectors and sockets are misaligned, or if the module is of the wrong type.

i) If the module being replaced is a MAU, connect the optical fibre connections removed at Step d).

j) Pull up on the bottom lever and press down on the top lever at the same time to ease the module into the backplane, until the red power switch in the bottom lever clicks into place.

k) Tighten the captive lock screw in each handle at the top and bottom of the module.

5.11 Replace a Siemens Zone Controller Housing Backplane

a) Disconnect the power connectors from the connections labelled 24V-A and 24V-B on the rear of the housing.

b) Remove the panel in front of the Addressing Plug from the front of the housing to improve access to the Addressing Plug. It might be necessary to remove one or more modules or blanking plates to improve access.

c) Remove the seals covering the Addressing Plug retaining screws, release the two screws and pull the Addressing Plug forward and out of the housing.

d) Remove the six SMB cables or terminators from the SMB connections on the rear of the housing.

e) Remove and retain the eight screws from the top and bottom of the cover plate and remove the cover.

f) Carefully mark the position of the backplane on the housing to check the connectors on the replacement backplane align correctly with the rails supporting the modules.

g) Remove and retain the remaining twelve screws holding the backplane on to the housing and remove the backplane.

h) Check the replacement 10-Slot plus Addressing Plug backplane is the same type as the one removed.

i) Align the backplane to the alignment marks made in Step f).

j) Note the position of the slots in the protective cover and attach the backplane to the housing using the twelve screws removed at Step g) so that the screws align with the slots in the protective cover.

k) Fit the protective cover plate using the eight screws removed in Step e).

l) Visually check the cables removed for damaged connector pins. If necessary, replace the cable with a serviceable spare.

m) Re-fit the SMB cables and terminators to the SMB connectors.

n) Reconnect the power connections and SMB connections, checking each cable is fitted to the correct connector. If in doubt, refer to the site records.

o) Fit the Addressing Plug removed from the failed backplane into the replacement backplane and secure it using the retained fixings.

p) Fit new red seals covering the retaining screws on the Addressing Plug.

q) Replace any modules removed.

5.12 Replace a Siemens Zone Controller PM Backplane

a) Power down the RSA which is plugged into the affected backplane by pressing the red button in the lower handle.

b) Disconnect the Ethernet cable and loopback connector from the connections labelled Ethernet A and Ethernet B.

c) Remove and retain the three screws from the top and bottom of the cover plate and remove the cover.

d) Carefully mark the position of the backplane on the housing so that the connectors on replacement backplane align correctly with the rails supporting the RSA modules.

e) Remove and retain the remaining three screws holding the backplane on to the housing and remove the backplane.

f) Two solder links are provided on the PM backplane to select if the PM is the Primary or Secondary PM. These are not used by the RSA and can be left open.

g) Align the backplane to the alignment marks made in Step d).

h) Note the position of the slots in the protective cover and attach the backplane to the housing using the three screws removed at Step e) so that the screws align with the slots in the protective cover.

i) Fit the protective cover plate using the three screws removed in Step c).

j) Visually check the Ethernet cable and loopback connector for damaged connector pins. If damaged pins are present, replace the cable or loopback connector with a serviceable spare.

k) Reconnect the Ethernet cable and loopback connector, checking they are in the correct socket. Refer to the site records.

5.13 Replace a Siemens Zone Controller Surge Interface Board

a) Power down the SOM110 which is plugged into the affected interface board by pressing the red button in the lower handle.

b) Disconnect the I/O connection cable at the back of the housing from the affected interface board.

c) Remove and retain the four screws and washers from the top and bottom of the cover on the lower half of the interface board and remove the cover.

d) Carefully mark the position of the interface board on the housing so that the connectors on the replacement interface board align correctly with the rails supporting the modules.

e) Remove and retain the socket head screws holding the connector spacers and interface board on to the housing and remove the spacers and interface board. Spacers for 16HP width modules retained with six screws. Spacers for 8HP width modules retained using four screws.

f) Check the replacement interface board is the same type as the one removed.

g) Align the backplane to the alignment marks made in Step d).

h) Attach the backplane to the housing using the screws and spacers removed at step e. The screws pass through the top half of the upper spacer and through the bottom half of the lower spacer.

i) Fit the protective cover plate to the bottom half of the interface board using the four screws and washers removed in Step c).

j) Visually check the I/O connection cable for damaged connector pins. If damaged pins are present, replace the cable with a serviceable spare.

k) Reconnect the interface cable.

Replace a WESTLOCK FEP PM Backplane

a) Remove the two PMs from the FEP housing following the procedure in NR/SMTH/Part04/WL01 (Replace a WESTLOCK Interlocking Module).

b) Disconnect the four Ethernet cables and two power connections from the front panel of the FEP housing.

c) Disconnect the earth strap connecting the housing to the rear panel of the cubicle.

d) On each side of the FEP housing to be removed, identify and remove the crosshead screws securing the housing to the rear panel of the cubicle. Retain the screws and washers.

e) Carefully withdraw the housing from the cubicle.

f) Disconnect the Ethernet cables from the connections labelled Ethernet A and Ethernet B.

g) Disconnect the PM-PM Data Cable and PM-PM Status Cable connecting the two PM backplanes.

h) Remove and retain the screws from the top and bottom of the cover plate and remove the cover.

i) Carefully mark the position of the backplane on the housing to check the connectors on replacement backplane align correctly with the rails supporting the processor modules.

j) Remove and retain the remaining screws holding the backplane on to the housing and remove the backplane.

NOTE: *Two solder links are provided on the PM backplane to select if the PM is the Primary or Secondary PM.*

- The PM Backplane fitted to Slot 1 has LK1 closed and LK2 open.
- The PM Backplane fitted to Slot 2 has LK1 open and LK2 open.

k) Check the solder links on the new backplane are set correctly.

l) Align the backplane to the alignment marks made in Step i).

m) Note the position of the slots in the protective cover and attach the backplane to the housing using the three screws removed at Step j) so that the screws align with the slots in the protective cover.

n) Fit the protective cover plate.

o) Visually check the cables for damaged connector pins. If damaged pins are present, replace the cable with a serviceable spare.

p) Reconnect the Ethernet cables and status connections to the two PM backplanes.

q) Check each cable is fitted into the correct connector and replaced as labelled.

r) Fit the housing into its correct position and secure using the four crosshead screws and associated lock washers removed in Step d).

s) Visually check cables (removed at Step b) for damaged connector pins. If damaged pins are present, replace the cable with a serviceable spare.

t) Reconnect the Ethernet cables and power connections to the front of the FEP Housing, checking each cable is fitted into the correct connector. If in doubt, refer to the site records.

u) Insert each processor module into the housing following the procedure in NR/SMTH/Part04/WL01 (Replace a WESTLOCK Interlocking Module).

5.14 Replace a Siemens FEP/ZC Addressing Plug

a) Disconnect the power connectors from the connections labelled 24V-A and 24V-B on the rear of the housing.

b) Remove the panel in front of the Addressing Plug from the front of the housing to improve access to the Addressing Plug. It might be necessary to remove one or more modules or blanking plates to improve access.

c) Remove the seals covering the Addressing Plug retaining screws, release the two screws and pull the Addressing Plug forward and out of the housing.

d) Check the replacement Addressing Plug is the same type as the one removed.

5.15 Configuring an Addressing Plug

If a pre-configured spare Addressing Plug has been supplied for the Housing, move to Step 5.16).

a) Dismantle the new Addressing Plug by removing and retaining the four screws from the top and bottom and remove the cover.

b) All links in the new Addressing Plug are made. Links are cut to set the Housing and Installation addresses and configure the SMB communications.

c) Identify the links to be removed by reference to the drawing in the site-specific documentation.

d) Cut each link to be removed at both ends. Check all cut ends are removed from the module.

e) Re-check the Addressing Plug against the drawing.

f) Re-assemble the Addressing Plug.

g) Fit red seals to the Addressing Plug and apply the correct labelling.

5.16 Installing a new Addressing Plug

a) Fit the Addressing Plug into the FEP/ZC and secure it using the retained fixings.

b) Fit new red seals covering the retaining screws on the Addressing Plug.

c) Replace any front panels or modules.

d) Place the removed Addressing Plug in the transit packaging.

5.17 Replace a Siemens FEP/ZC Power Supply Module

a) Disconnect the plug couplers on the rear of the Power supply module (at the rear of the housing).

b) Release the four captive screws retaining the Power supply module located on the front panel.

c) Using the handles, slide the Power supply module out of the housing.

d) Slide the new Power supply module into the rack (checking correct orientation).

e) Locate and tighten the four cassette retaining screws.

f) Replace the plug couplers on the rear of the cassette (plug couplers are physically different and only plugs into one place).

5.18 Replace a Siemens Zone Controller Power Buffer Unit

a) Disconnect the Buffer Unit plug coupler on the rear of the power supply module.

b) Extract the Buffer Unit cable from any cable management.

c) Mark the Buffer Unit’s position on the DIN rail.

d) Detach the Buffer Unit from the DIN rail. The release mechanism is located underneath the buffer unit and is operated with a flat blade screwdriver.

e) Attach the new Buffer Unit to the DIN rail in the same position as the previous one.

f) Route the buffer cable via the cable management.

g) Plug the buffer unit plug coupler into the rear of the power supply module.

5.19 Replace a Siemens Zone Controller TPWS Circuit Breaker

a) Disconnect the wires from the faulty circuit breaker.

b) Remove the circuit breaker fixings.

c) Remove the finger guard and faulty circuit breaker.

d) Align the replacement circuit breaker and finger guard to the fixing holes in the plate.

e) Refit the circuit breaker retaining fixings.

f) Check the new circuit breaker lever operates correctly, before returning it to the off position.

g) Reconnect the wires to the circuit breaker.

h) Refit finger guard.

5.20 Replace a Siemens Ethernet Switch Power Supply

a) Disconnect the wires from the Power Supply Unit.

b) Mark the Power Supplies position on the DIN rail.

c) Detach the Power Supply from the DIN rail. The release mechanism is located underneath the unit and is operated with a flat blade screwdriver.

d) Attach the new Power Supply to the DIN rail in the same position as the previous one.

e) Connect the wiring.

5.21 Replace a Siemens Ethernet Switch Power Buffer Unit

a) Disconnect the Buffer Unit from the Power Supply Unit.

b) Disconnect the output from the buffer unit one wire at a time to check the two wires cannot short the capacitors as they are withdrawn.

c) Mark the Buffer Unit’s position on the DIN rail.

d) Detach the Buffer Unit from the DIN rail. The release mechanism is located underneath the buffer unit and is operated with a flat blade screwdriver.

e) Attach the new Buffer Unit to the DIN rail in the same position as the previous one.

f) Connect the output from the buffer unit one wire at a time to checking the two output wires do not short the capacitors.

g) Connect the buffer unit to the power supply.

5.22 Replace a Siemens AMI-SRA Modular Technicians Facility PC

a) Isolate the power supply using the MCB.

b) Unplug the cables from the PC.

c) Remove and retain the Removable Drives and compact flash card (if used).

d) Remove and retain the fixing securing the PC to the bracket and withdraw the PC.

e) Insert the retained Removable Drives and compact flash card (if used) into the replacement PC.

f) Secure the PC in position using the retained fixings.

g) Check the cables are in the correct position and then re-connect.

h) Re-apply the power supply using the associated MCB.

5.23 Replace a Siemens Zone Controller MAU Backplane

a) Disconnect the power connectors from the connections labelled 24V-A and 24V-B on the existing MAU backplane on the rear of the housing.

b) Remove the two SMB cables or terminators from the SMB connections on the MAU backplane.

c) Remove and retain the four screws from the top and bottom of the cover plate and remove the cover.

d) Carefully mark the position of the backplane on the housing so the connectors on replacement backplane align correctly with the rails supporting the modules.

e) Remove and retain the remaining four screws holding the backplane on to the housing and remove the backplane.

f) Check the replacement WESTRACE MAU backplane is the same type as the one removed and has been supplied by Siemens Rail Automation.

g) Align the backplane to the alignment marks made in Step d).

h) Note the position of the slots in the protective cover and attach the backplane to the housing using the four screws removed at Step e) so that the screws align with the slots in the protective cover.

i) Fit the protective cover plate using the four screws removed in Step c).

j) Visually check the cables or terminators (removed at Step b) for damaged connector pins. If necessary, replace the cable with a serviceable spare.

k) Reconnect the power connections, SMB connections and terminators, checking each cable is fitted to the correct connector. If in doubt, refer to the site records.

l) Place the removed backplane in the transit packaging and return it to Siemens Rail Automation for repair.

5.24 Replace a Siemens Zone Controller Housing

a) Power down the modules in the housing by pressing the red button in the lower handle on each module.

b) Disconnect the power connectors from the connections labelled 24V-A and 24V-B on the rear of the housing.

c) Remove the six SMB cables or terminators from the SMB connections on the rear of the housing.

d) If an RSA is fitted to the housing, disconnect the Ethernet cable and loopback connector from the connections labelled Ethernet A and Ethernet B.

e) If a MAU is fitted, disconnect the optical fibre connections from the front of the MAU taking care to protect the ends.

f) Disconnect the I/O connection cable at the back of the housing from each interface board.

g) To reduce the weight of the housing, remove the modules by swinging the handles outwards and slide the module out of the housing along the guides.

h) Remove the panel in front of the Addressing Plug from the front of the housing to improve access to the Addressing Plug.

i) Remove the seals covering the Addressing Plug retaining screws, release the two screws and pull the Addressing Plug forward and out of the housing.

j) Remove and retain the eight screws holding the housing into the rack located on the front of the housing.

k) Using the handles, slide the housing out of the rack (the housing is supported by runners).

l) Slide the new housing into the rack (checking correct orientation).

m) Refit the four housing retaining screws.

n) Fit the modules to the new housing and check the backplanes are fitted in the correct position behind the modules.

o) Remove the housing backplane from the redundant housing and fit it to the new housing following the procedure in NR/SMTH/Part04/WL08 (Replace a Siemens Zone Controller Housing Backplane).

p) Remove any PM backplanes from the redundant housing and fit them to the new housing following the procedure in NR/SMTH/Part04/WL09 (Replace a Siemens Zone Controller PM Backplane).

q) Remove the Surge Interface Boards from the redundant housing and fit them to the new housing following the procedure in NR/SMTH/Part04/WL10 (Replace a Siemens Zone Controller Surge Interface Board).

r) Remove any MAU backplanes from the redundant housing and fit them to the new housing following the procedure in NR/SMTH/Part04/WL11 (Replace a Siemens Zone Controller MAU Backplane).

s) Fit the Addressing Plug removed from the redundant housing into the new housing and secure it using the retained fixings. It might be necessary to remove one or more modules to improve access.

t) Fit new red seals covering the retaining screws on the Addressing Plug.

u) Replace any front panels or modules.

v) Press the red button in the lower handle of each RSA, MAU and LOM110 or SOM110 module to check the modules are switched off.

w) Re-connect the cables.

5.25 Replace a Siemens Zone Controller Power Distribution Housing

a) Disconnect the plug couplers on the rear of the Power Cassettes (at the rear of the housing).

b) Remove and retain the four screws holding the housing into the rack located on the front of the housing.

c) Using the handles, slide the housing out of the rack (the housing is supported by runners).

d) Slide the new housing into the rack (checking correct orientation).

e) Refit the four housing retaining screws removed at Step b).

f) Replace the plug couplers on the rear of the cassettes (plug couplers are physically different and only plugs into one place within a cassette).

g) Turn on the upstream circuit breakers.

h) Turn on each circuit breaker on the front panel of the cassettes.

i) If the Power Cassette is a 24VDC cassette part number C52986/1, verify the green “DC Ok” status indicator on the front of the Power Cassette illuminates.

5.26 Replace a Siemens Zone Controller I/O Cable

a) Power down the IOM which is plugged into the affected I/O Connection Cable by pressing the red button in the lower handle.

b) Disconnect the I/O Connection Cable from the back of the housing from the affected interface board.

c) Extract the I/O Connection Cable from any cable management.

d) Disconnect the I/O Connection Cable from the Wago terminals.

e) Route the new I/O Connection Cable via the cable management.

f) Connect the new I/O Connection Cable to the Wago terminals according to the site-specific documentation.

g) Connect the new I/O Connection Cable to the back of the housing.

END

1. GENERAL

1.1 A BR Western Region coded track circuits fundamentally differ from a conventional steady energy DC track circuit in that the voltage, supplied to both rails at the feed end, is broken up into a code comprising alternate periods of positive and negative impulses (Figure 1).

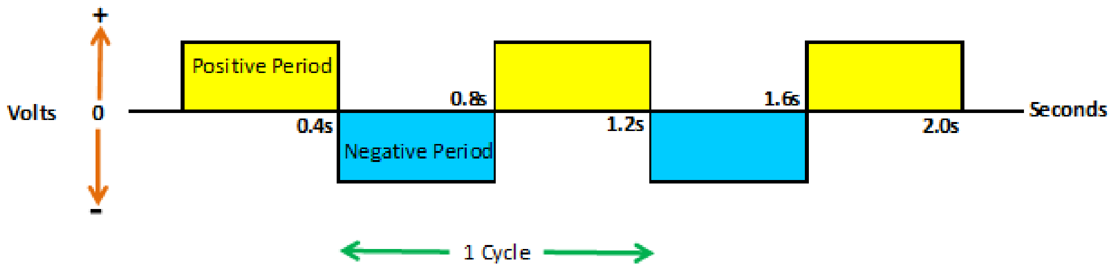

Figure 1 – 75 CPM Code

1.2 The code is produced by a coded transmitter (CT). It's oscillating contacts interrupt and alternate, a 2v Lead Acid battery supply at the feed end of the track circuit.

1.3 At the relay end of the track circuit the code is received by a 2 ohm Polar Biased code following relay (CFR). When working correctly, the CFR follows exactly the alternate code produced by the CT, and this produces the distinctive "tick-tock" at the CFR, at a rate of 75 cycles per minute.

The advantages arising from the use of DC Coded Tracks are:

a) Longer track circuits can be operated for a minimum ballast resistance.

b) The track cannot be falsely energised by an extraneous DC source.

c) There is no "battery storage effect" in poor ballast conditions.

1.4 Due to the DC coded track circuits alternating polarities, in order to interface with the signalling and provide contacts for signalling control and TPRs etc, a slow-release DC neutral shelf type relay is employed.

1.5 Under track clear conditions the TR is maintained in a steady energised state by means of a decoding transformer (DT). As long as the correct 75 cycles per minute are received by the CFR, the DT will provide a unidirectional current through the TR.

Any interruption or distortion of the 75 CPM code will not only cause the CFR to stop oscillating, but also the TR to be de-energised. It is the TR contacts that are then used in the conventional manner.

1.6 Although the relay is called the TR it is NOT the TR that is shunted as it has no direct connection to the rails, and the independent power supply via the DT. It is the CFR that is tested. (Figure 2)

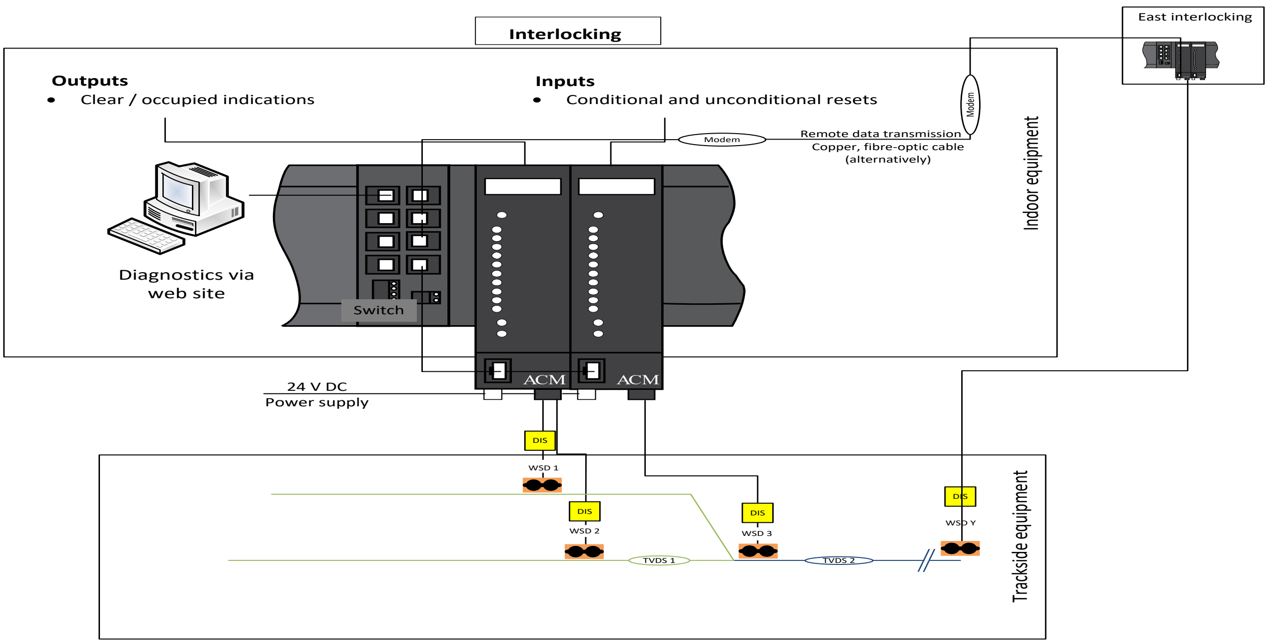
Table 1 – List of Abbreviations

Track Vacancy Detection with an Axle Counting System

The ACM100 system (figure 1) is used for automatic monitoring of open-line and station tracks. Clear and occupied indications are transmitted to the interlocking or to subsystems for track sections and points. The ACM100 system consists of two sets of equipment, Trackside and Indoor equipment.



ACM – axle counting module
DIS – disconnection box
TVDS – track vacancy detection section
WSD – wheel detector

Figure 1 – ACM100 overview

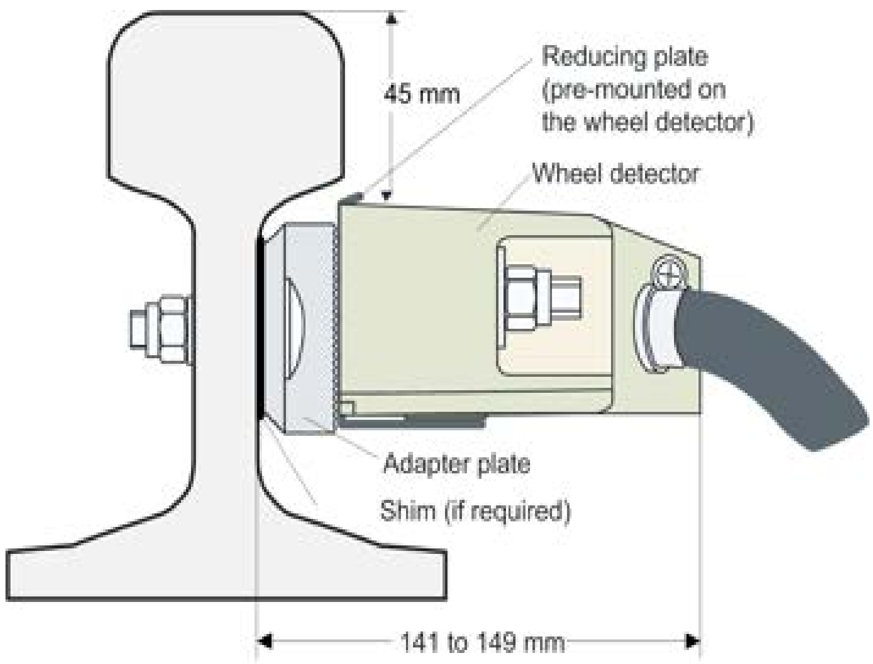
Wheel detection components are placed at the beginning and end of each track vacancy detection section (TVDS) to be monitored. To determine whether there is a vehicle in a TVDS, the system compares the number of axles entering it with the number leaving it.

WSD Wheel Detector

The WSDs (figure 2) are installed at the limits of a TVDS. A WSD consists of two independent detector subsystems (double wheel detector) installed in a glass-fiber reinforced plastic housing. The WSD requires a periodic (six monthly) recalibration and functional test. The recalibration process once triggered operates automatically, with no user serviceable components within the WSD housing. The WSD is mounted in the track on the gauge side of the rail. The wheel detector is connected to a trackside connection box (cable distribution box) by a four-core cable (two cores per detector subsystem). The cable is 5 m (optionally 10m or 15m) long. The WSD wheel detector is either bolted to the rail web or clamped to the base of the rail.

Figure 2 – Wheel Sensor Double (WSD)

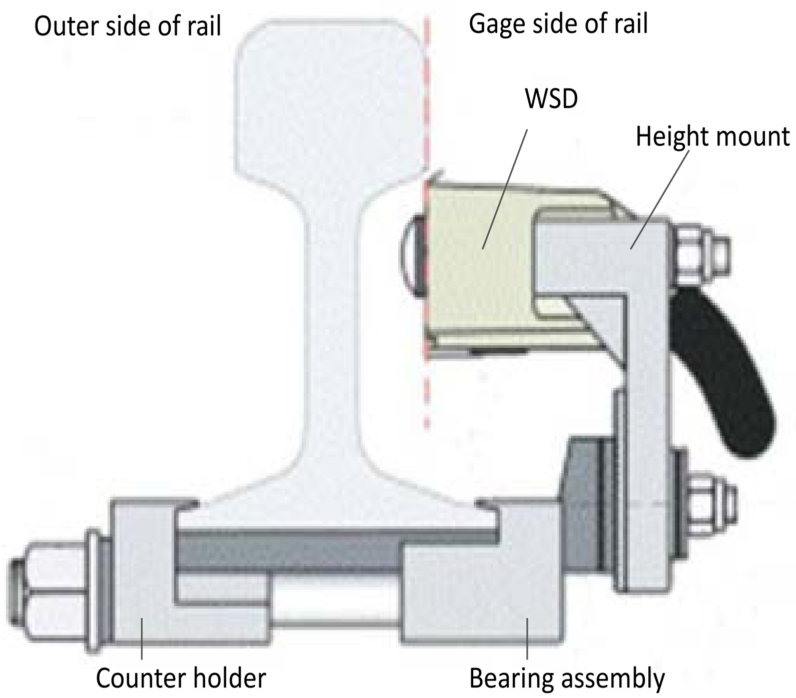
Planning stipulates whether rail web or rail base attachment is to be used. The rail base attachment is rail specific. The correct rail base bracket is to be used with the correct rail type. Both types of mountings are shown in figures 3 and 4.



The rail web mount consists of:

Adapter plate
Fastening bolts
Washers
Prevailing torque-type nuts
Shim (if required)

Figure 3 – Rail Web Mounting of WSD



The rail base mount consists of:

Wheel detector
Fastening bolts
Washers
Prevailing torque type nuts
Counter holder
Damping plate
Studs
Height Mount
Seperator
Bearing assembly
Nuts
Bearing plate
Courugated plate
Reducing plate

Figure 4 – Rail Base Mounting of WSD

Special Tools Required (Web and Base Mounting)

Figure 6 – Indoor Equipment

ACM100 Evaluator

The Indoor equipment consists of a combination of standard modules (ACM100) which form an axle counting system. The ACM100, see above, has the following functions:

- Evaluation of the signal pulses transmitted by the wheel detection components
- Comparison of the number of axles counted into a track vacancy detection section with the number of axles counted out.
- Monitoring of the track vacancy detection sections and output of the clear and occupied indications.
- ACM100 has a 2-out-of-2 computer configuration, based on the fail-safe Simis principle.
- The process data (passage of a wheel) is detected by the WSD, processed and transmitted to the assigned ACM100. The ACM100 processes and evaluates the WSD signals and indicates the results to the interlocking.

Figure 7 – ACM100 Evaluator

Conditional and unconditional resets can be realised as inputs from the interlocking. The reset restriction can be cancelled from the interlocking using an optional dual-channel auxiliary axle count reset (AZGH) operation. This is also possible directly on the ACM100.

Front Panel

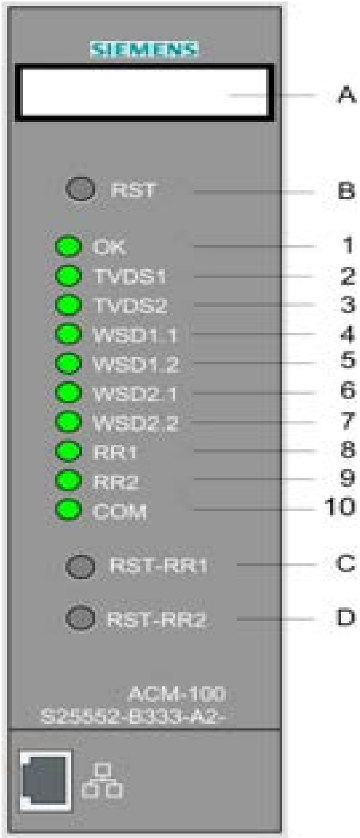

Figure 8 – ACM100 Front Panel

Item	Element	LED Condition	Meaning
A	ID plug		Configuring connector with lettering field
B	RST		Reset button (resets the ACM100)
1	OK LED	Steady green	ACM100 OK

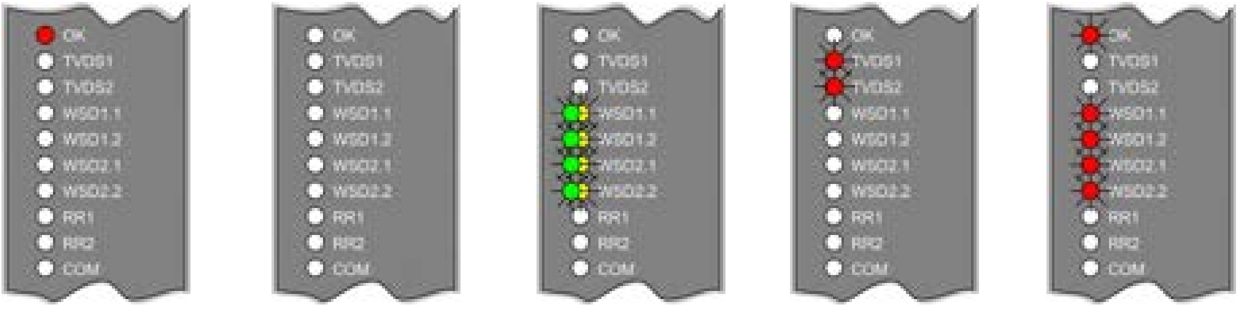
		For safety-related information and WSD "pulse detected" indication	
		Steady green	No button fault
		Steady red	Button fault
		For no TVDS and no safety-related information	
		Steady red	Button fault
9	RR2 LED	**Reset restriction 2 (RR indication for TVDS 2)**	Refer to RR1
10	COM LED	**Communication**	
		Steady green	All fail-safe connections OK
		Steady yellow	≥ 1 fail-safe connection has failed
		Steady red	Fault in computer unit
		Flashing red	No physical connection
C	RST-RR1	Reset button for reset restriction 1	Cancelation of reset restriction for TVDS 1 (AZGH) As from ERL 6, for confirmation after replacement of an ACM100
D	RST-RR2	Reset button for reset restriction 2	Cancelation of reset restriction for TVDS 2 (AZGH) As from ERL 6, for confirmation after replacement of an ACM100

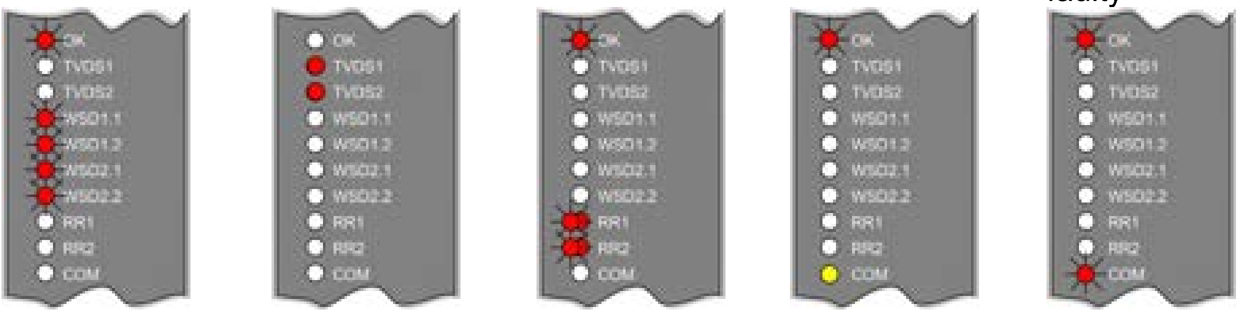
Table 2 – LED Indications and Meaning

Diagnostic Overview

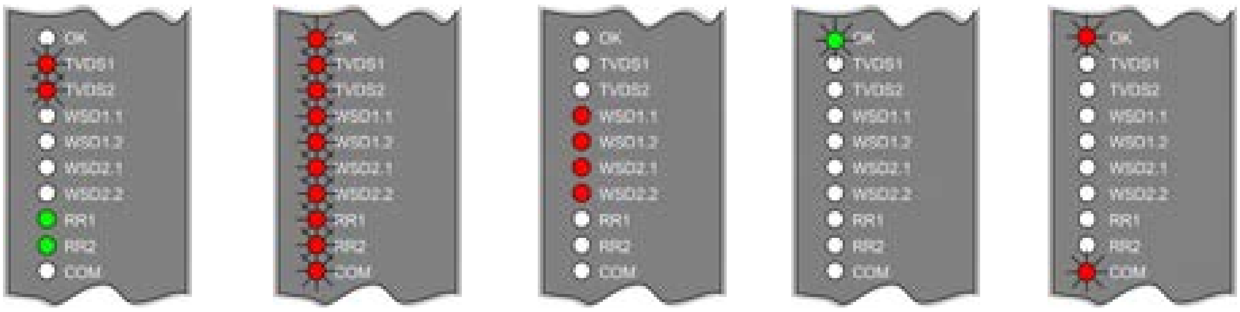
Figure 9 shows the LED fault indication status.



ACM100 has failed | Power supply board has failed | WSD wheel detector faulty | Track vacancy detection section faulty | ERL 4: ACM100 blocked or faulty



As from ERL 5:ACM100 faulty) | Track vacancy detection section permanently occupied | Button fault | Connection to partner ACM100 has failed | Ethernet connection interrupted



SRI has failed | ID plug faulty | WSD wheel detector(s) or cable faulty | Configuration acceptance mode | Replacement of ACM100

Key - LED representation:

A: LED shows a steady red light
B: LED shows a flashing red light
C: LED shows a steady or flashing red light
D: LED shows a flashing green or yellow light
(all indications with other colours are possible)

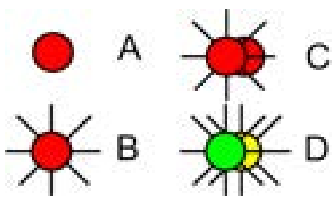


Figure 9 – LED fault indication status

Reset Procedure

The resetting of the Siemens ACM100 axle counter is performed by the signaller.

The reset procedure shall be performed when:

a) An axle counter section remains occupied after the passage of a train when the track section is 'clear'.

b) Requested by the technician after faults.

Power Supply

The power supplies from the Simatic S7-300 range supply the power required for the ACM100 system. From the input voltage, they generate a supply voltage of 24 V DC. Different types of power supplies are used depending on the application variant. The green LED on the front panel indicates that an output voltage is present.

Figure 10 – Power Supply

Figure 11 – Front Panel

Item	Element	Meaning / function	State in normal operation
1	DC 24 V LED	24 V DC output voltage is present	On
2	ON / OFF switch	On / off switch for 24 V DC	-
3	Terminals	Connection of mains voltage and protective earth conductor	-
4	Terminals	Connection for 24 V DC	-

Diagnostic Indicators

See ACM diagnostic overview for LED indication.

c) If …	d) Then …
all LEDs on other ACMs are off as well,	The power supply board is faulty. • Check the power supply board
all LEDs on only one ACM are off,	The ACM has failed or the cable connection is interrupted. First: • Replace the ACM.
the LEDs still remain off after ACM replacement,	The cable connection is interrupted. Check the cable connection between the ACM and the power supply board. • Check the connectors and check them for a secure fit. • Perform a visual inspection to see if there is any damage (kinks, cable jammed, insulation damaged). • Replace any faulty parts.

Table 4 – Diagnostic Indicators

Battery Module

Weight	3.2 kg / 7 lbs.
Overall dimensions	W 190 mm H 151 mm D approx. 82 mm
Battery	2 pcs, maintenance free AGM batteries 12V/3,2Ah
Type	Yuasa NP3, 2-12 or B. B. Battery BP3, 6-12
Fuse	Blade fuse 15A

Table 5 – Battery Details

Figure 12 – Battery Module

Permitted temperature	Operation -15...+50°C storage/ transport -20...+50°C. Operating conditions acc. to EN 60721-3-3, climate model 3K3, no condensation
Self-discharge	The self-discharge rate of the batteries is approx. 3% per month at a temperature of 20°C. This value depends on temperature and gets worse with increasing temperature and, resp., better with falling temperature.
Class of protection	III acc. to IEC 536; VDE 0106 Part 1 Preferably, the natural protective conductor connection through the fittings should be used. Degree of protection: IP00 acc. to IEC 529

Table 6 – Battery Operating Conditions

Uninterruptable Power Supply (UPS)

The DC-UPS module 6 is DIN rail mounted. If the 24V DC supply voltage fails or drops below the set cut-in threshold, the battery module, which is maintained at full charge in continuous supply mode, is connected in to supply the loads. The battery cut-in threshold, end-of-charge voltage, charging current and the buffering time are set via DIP-switches. A switch is provided for setting a defined buffering (stored energy) time with subsequent disconnection of the battery.
The operating states of the DC-UPS module 6 are signalled by four LEDs:

- Normal Operation (Green)
- 85% Charge (Green)
- Floating Operation (Yellow)
- Battery Not Ready (Red)

Figure 13 – UPS Module

"Normal operation" indicates the input voltage at the DC-UPS module is higher than the set cut-in threshold. The loads are being fed by the line-side power supply. If a battery module is connected, it is fully charged.

“>85% charge”, indicates the battery is charged more than 85% of its available capacity.

"Floating operation", indicates the input voltage is lower than the set cut-in threshold and the ACM100 equipment is being supplied by the battery module.

"Battery not ready" indicates one of the following, all of which require corrective maintenance:

- defective battery (battery voltage < 18.5V) or open circuit between battery and UPS module
- no battery module connected,
- reversed polarity

The interval for polling the operating state for "Battery not ready" is 20 seconds during normal operation. If a fault is rectified, the LED can remain lit for up to 20 seconds until updated at the next polling.

If the LED flashes in a 2s cycle, this indicates that the battery is defective, but still capable of floating operation. The specified hold-up times cannot be kept in such cases. **The battery module shall be replaced.**

The LED lit in **floating operation** means that the battery voltage has dropped to <20.4V and automatic disconnection to protect the battery is imminent.

When the battery has been disconnected due to overload, short circuit, exhaustive discharge protection or buffering timeout, all LEDs will switch off however the relay contact X2.4 – X2.5 will remain closed.

DIP Switch Settings

Note: L = switch positioned left (on) and R = switch positioned right (off).

Top DIP1, 2 & 3: Sets the cut-in threshold such that if the input voltage drops below this threshold the UPS module switches to the battery supply. The setting range is 22.0 to 25.5V DC in 0.5V steps -

Cut-in Voltage (V)	22.0	22.5	23.0	23.5	24.0	24.5	25.0	25.5
DIP1	R	R	R	R	L	L	L	L
DIP2	R	R	L	L	R	R	L	L
DIP3	R	L	R	L	R	L	R	L

Table 7 – DIP Switches (1)

Top DIP4, 5, 6, 7, 8 & 9: Sets the end of charge voltage threshold above which the battery stops charging. The setting range is 26.3 to 29.2V DC in 0.1V steps -

End of Charge Voltage (V)	26.3	26.4	26.5	26.6	26.7	26.8	26.9	27.0	27.1	27.2	27.3
DIP4	R	R	R	R	R	R	R	R	R	R	R

Table 11 – DIP Switches (5)

Bottom DIP8: Sets if the battery supply output maximum time is reduced by 5 seconds. The settings are 5 second reduction (DIP8 = L) or no reduction (DIP8 = R).

Bottom DIP9: Sets the operational state of the battery when supplying the output. The settings are fully functional (DIP9 = L) or no battery output (DIP9 = R).

Ethernet Switch

The ACMs are connected using the Scalance Ethernet switches. ACMs are connected to the switch via RJ45 sockets. For diagnostic purposes, a service PC or laptop can be connected to the switch. The power supply is connected via terminals.

The operating and display elements (LEDs, buttons) depend on the type of switch used. Detailed information may be found in the documentation for the relevant switch.

See ACM diagnostics overview for LED indication.

Figure 14 – Ethernet Switch

End

Includes:	All Thales Axle Counter Systems
Excludes:	All other types and makes of Axle Counter System

GENERAL

Thales equipment was previously known as Alcatel Systems.

1. Test Equipment (Where required)

There are certain items of specialist equipment required to complete all the testing on axle counter equipment; these are as follows:

a) Dummy Wheel (for the type of system to be tested).
b) Counting Test Unit (Not Essential).
c) Thales Test Unit.
d) Wago Termination Tool (do not use a screwdriver).
e) ISDN Dataline Tester.
f) Lineside Test Switch Box (silver suitcase, use with electronic meter).
g) Axle Counter Test Box (AzLM series).
h) Diagnostic PC.

2. Detection points (ZP)

A Thales detection point (ZP) is comprised of 2 field elements. A rail contact (count head), which is mounted to the rail, and a line side junction box (EAK) which is usually mounted in the cess of sometimes the 10ft. The 2 elements are connected via tail cables and together for the detection point (ZP).

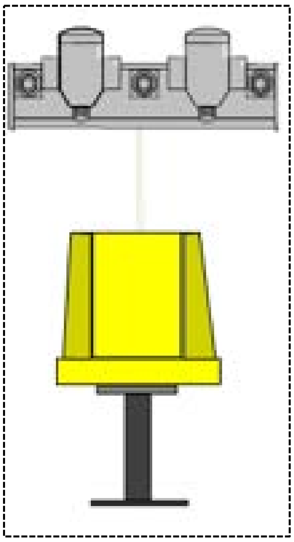

Figure 1 – ZP 30H Style

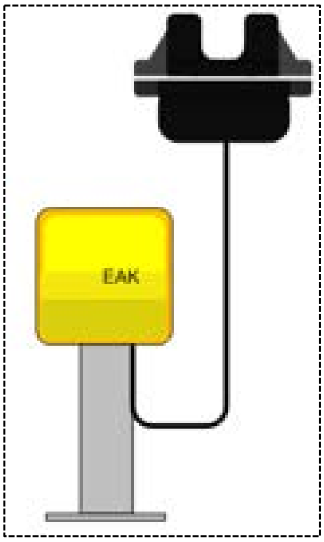

Figure 2 – ZP 30K Style

3. Rail Contacts (Count Heads)

Single rail contact systems are fitted with SK11 count heads and double rail contact systems with SK30. The latest types are the SK30H & SK30K types, which are backward compatible with the SK30 but with different voltage tolerances (MESSAB and PEGUE).

If SK30, SK30H & SK30K heads are fitted to bullhead rail a flux plate should also be fitted with them to obtain the correct phase reversal voltages (Where fitted).

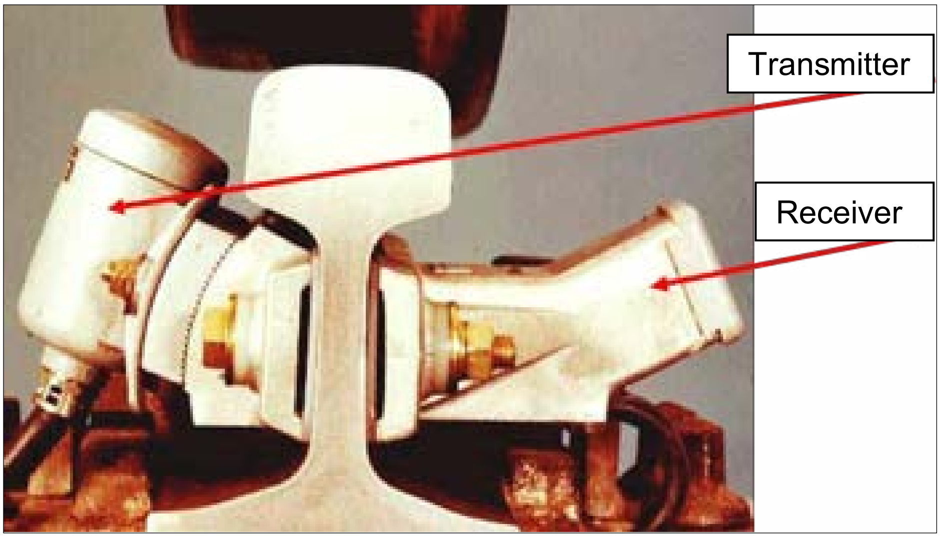

Figure 3 - View of Thales count heads (SK30H)

Figure 4 - View of Thales count heads (SK30K)

4. Lineside Junction Boxes (EAK)

The cable cores (from the rail contact cables) from the cable clamp to the terminations in the EAK are to be twisted together between these points. This is to reduce signal loss.

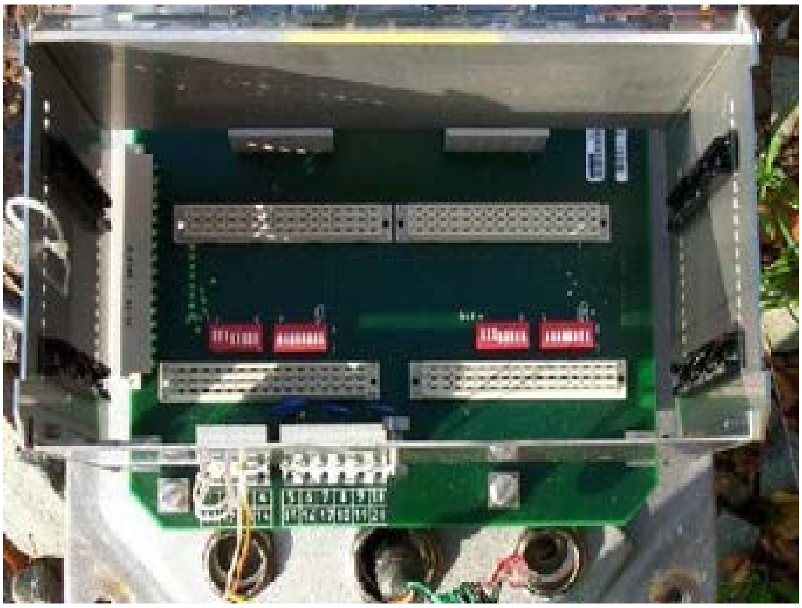

Figure 5 - Top View of the EAK30H Lineside Junction Box

The evaluator batteries and the EAK30H local power supply batteries (where provided) are ‘sealed for life’ and therefore apart from cleaning do not require maintenance.

Figure 6 - Top View of the EAK30K Lineside Junction Box

5. AzL70 Series

There are four versions of the AzL70 axle counters; they all work on the principle of counting in at one set of count heads and counting out at another. The count in and out information is processed in the evaluator, which feeds an output to a TPR. The different types are listed below:

AzL70 Single Rail Contacts:

This is the earliest type of the AzL70 series and is a two rail system (SK11 rail contacts on the 6ft and cess rails) with a stagger between the two rail contacts.

The stagger distance is chosen by the manufacture to enable the system to detect trains travelling at the highest specified speed.

This distance must not be altered from its original setting, if due to rail creep the stagger distance alters; arrangements must be made to correct it.

The rail contacts are connected to the evaluator via a four wire cable, the TX frequencies for each count head are the same thus the signals are sent back on separate wires to an AzL70 evaluator.

The lineside junction box is an EAK unit that does not have pluggable circuit cards.

AzL70 Double Rail Contacts:

This is a one rail version with SK30 rail contacts. Both of the rail contacts fixed to one rail (usually the cess). Again they are staggered but with both attached to one mounting plate the distance between them is pre-defined therefore rail creep is not a problem.

The lineside junction box is an EAK30 unit having pluggable cards. This unit enables signals of different frequencies to be sent along a common cable pair (a two-wire transmission system) to an AzL70 evaluator with amended configuration strapping.

AzL70/30 High Frequency Double Rail Contacts:

This is a single rail version with SK30 rail contacts. It uses an EAK30 lineside junction box with a two-wire transmission system to an AzL70/30 evaluator which has a different card configuration to the previous types.

AzL70/30S Voice Frequency Double Rail Contacts:

This is similar to the previous system but the outputs from the EAK30 units are at a lower frequency, therefore some of the cards in the EAK30 and evaluator are slightly different.

Because of the variations in type and updates that have occurred it is important that you check the part codes on any cards before replacing them.

Although the cards might look the same and have the same name, if the codes are different they are not inter changeable.

Evaluators

Before removing any card from an evaluator rack, it is necessary to power-down the rack equipment to avoid damage. This is done by removing the fuse feeding the rack.

On all evaluators the count indicator board (ZIANZG) provides indication only, it is not required for operation of the axle counter system therefore you may find that not all evaluators at a site are fitted with them.

AzL70 Evaluator

This evaluator is used on both the AzL70 one and two rail versions. Because of the EAK30 unit on the one rail contact system the evaluator although the same type for both systems has a different strapping configuration to handle the different frequencies involved.

AzL70/30 Evaluator

This type of evaluator differs from the AzL70 type by having a combined input set (LTV-E count in and LTV-A count out). The reset restrictions have also been revised (GRDFR in place of FRMKTR). The other cards in the system perform similar functions as in the AzL70.

6. AzLM Series

AzLM consists of the Axle Counter Evaluator (ACE) and one or more detection points.

There are two variants of the detection point which can be used electively within the AzLM; Zp30H or Zp30K.

The ACE is available with a 2oo2 (Parallel) or 2oo3 (WNC) architecture.

The ACE architecture can be centralised or distributed. A centralised solution can use the Convertor ISDN / Ethernet (CIE).

A detection point DP consists of an Electronic Junction Box (EAK) and rail contacts Sk with cable:

a) Detection point Zp30H with rail contacts Sk30, Sk30H and Sk30K (with new analogue card).

b) Detection point Zp30K with rail contacts Sk30K

Up to 32 sections can be supervised from one ACE. An ACE reports the state of a section via a parallel relay interface to a relay interlocking.

7. AzLE Series

This type of evaluator unit can be used with either ZP30H or ZP30K type detection points. It can be located either in an axle counter REB or a trackside location case.

The unit is the same size as an AzLM 2-10 and manages up to 8 sections and 12 detection points.

Although still a 2 out of 2 evaluator with relay interface, it differs to the AzLM by using modem and section boards as opposed to serial, CPU and parallel boards.

Interface to the detection point is achieved via 2 x copper wire ISDN, however no PDCU is required as surge/lightening protection is built into the modem boards. Site specific data is stored on a programme plug as opposed to a compact flash card.

Detection point power supply: The AzLE subrack can accommodate up to 3 detection point power supply boards. Each detection point power supply board can remotely supply a maximum of 4 detection points (ZPs)

Internal power supply board: The AzLE subrack can accommodate up to 2 internal power boards to supply the modem and section boards. The number of required in internal power boards is dependent on how many section and modem boards are to installed.

Section board: The AzLE subrack can accommodate up to 4 section boards. Each section board performs as a 2 out of 2 system and can supervise up to 2 sections dependant on configuration. The section board can be configured for 2 or 3 vital relay outputs and has vital inputs similar to the AzLM. Non vital outputs are also available and configurable.

Modem board: The AzLE subrack can accommodate up to 3 modem boards which perform the interface to the detection point (ZP) via ISDN. Each modem board can connect up to 4 detection points and is configurable to forward the information of 1 of these detection points to another subrack.

Reset procedures are similar to that of AzLM.

Subrack:

8. Abbreviations Found in AzL Axle Counters

Abbreviation	Meaning
2oo2	2 out of 2
2oo3	2 out of 3
ACE	Axle Counter Evaluator
AZA	
AzLM	Multi Section Axle Counter
BG	Printed Circuit Board (PCB)
BGT	Sub rack
CPU	Central Processing Unit
DC	Direct Current
DP	Detection Point
E/A	Input/Output
EAK	Electronic Junction Box
E-Es	Electronic Module
I/O	Input/Output
KL	Terminal
S/E	Transmitter/Receiver
SK	Rail Contact
SSI	Solid State Interlocking
SV	Power Supply
VCC	Supply Voltage
Zp	Detection Point
ZpR	CPU in the detection Point

This list is not exhaustive; reference should be made to the appropriate system manuals for abbreviations not listed.

9. AzL70/30 EAK30 Junction Box Cards

Viewed left to right:

Card	Function
SE01	Tx/Rx for Count Head SK1
SE02	Tx/Rx for Count Head SK2
LtAnp	Cable Adaptor
SV	Power Supply

10. AZL70 Evaluator Rack Cards

Viewed left to right:

Card	Function
FRMKTR	Reset Restriction
ANP	Part Input Set
EV	Part Input Set
DIS	Part Input Set
	Repeat of above 3 cards for each input
ZST	Counter Control
Biz	Binary Counter
Biz	Binary Counter
UMO	Translator
KTR	Checking
AS	Output
ZIANZG	(If Fitted) Count Indication
WDH	Repeater
BUPL	Test Points
SIPL	Fuses
SVB	Power Supply B
SVA	Power Supply A
SBG	Filters

11. AzL70/30 Evaluator Rack Cards

Card	Function
GDRFR	Reset Restriction
LTV-E	Line Amplifier Count In
Dis	Discriminator
LTV-A	Line Amplifier Count Out
Dis	Discriminator
	Space (see note)
ZST	Counter Control
Biz	Binary Counter
Biz	Binary Counter
UMO	Translator
KTR	Checking
AS	Output
ZIANZG	(If Fitted) Count Indication
WDH	Repeater
BUPL	Test Points
SIPL	Fuses
SVB	Power Supply B
SVA	Power Supply A
SBG	Filters

If extra count heads for counting out are fitted (e.g. over a set of points) the LTV-A and Dis cards for this count head are fitted here.

12. LED Indications : SK30H

PCB	LED Position	LED Colour Status	What The Led Status Is Indicating	Normal Operating Led Status Without Wheel Influence
Analogue Card (Anpassung)	H1/1	Red	Wheel on Sk1	Off
	H1/2	Green	MESSAB1 in tolerance of PEGUE 1	Flashing
	H2/1	Red	Wheel on Sk2	Off
	H2/2	Green	MESSAB2 in tolerance of PEGUE 2	Flashing
	H3/1	Red	H24V out of tolerance	Off
	H3/2	Green	H5V O.K. / available	On
Digital Card (Auswertung)	H1/1	Green	Transmitting data, connection to ACE available	Flashing
	H1/2	Green	Self-test of CPU 1 not successful	Off
	H2/1	Green	Transmitting data, connection to ACE available	Flashing
	H2/2	Green	Self-test of CPU 2 not successful	Off

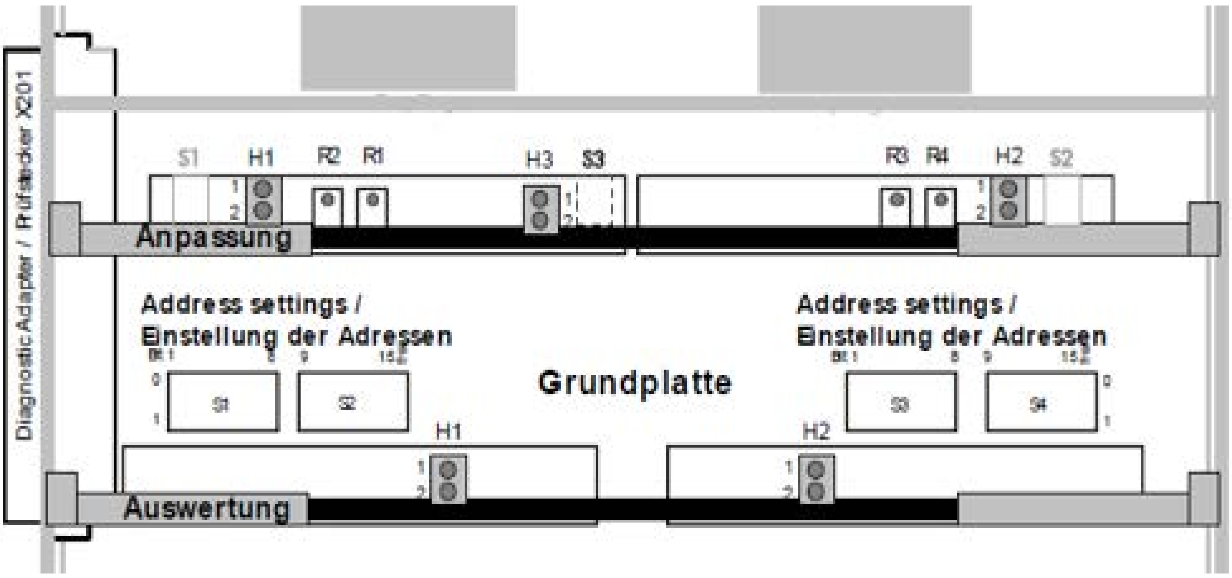

Figure 12 - Position of SK30H LED’s

13. LED Indications : SK30K

PCB	LED Position	LED Colour Status	What The Led Status Is Indicating	Normal Operating Led Status Without Wheel Influence
Analogue Part	H11	Red	wheel on Sk1	Off
	H1	Green	MESSAB1 in tolerance of PEGUE 1	Flashing
	H8	Red	Illuminate during fault conditions (Short circuit on Sk1)	Off
	H12	Red	wheel on Sk2	Off
	H2	Green	MESSAB2 in tolerance or PEGUE 2	Flashing
	H9	Red	Illuminate during fault conditions (Short circuit on Sk2)	Off
	H3	Red	H24V out of tolerance	Off
	H10	Green	H5V o.k. / Available	On
Digital Part	H4	Green	Transmitting data, connection to ACE available	Flashing
	H14	Red	Self-test of CPU 1 not successful	Off
	H6	Green	Transmitting data, connection to ACE available	Flashing
	H16	Red	Self-test of CPU 1 not successful	Off

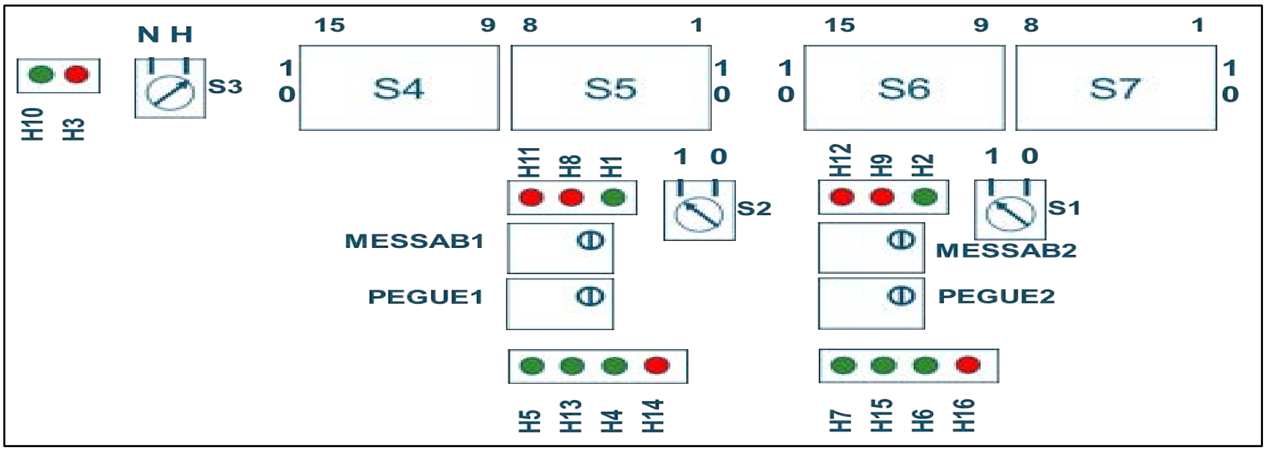

Figure 13 - Position of SK30K LED's

The switch positions on this card should be S1=1, S2=1, S3=H

14. LED Indications : Evaluator Serial I/O Card (Zp-Vorrechner)

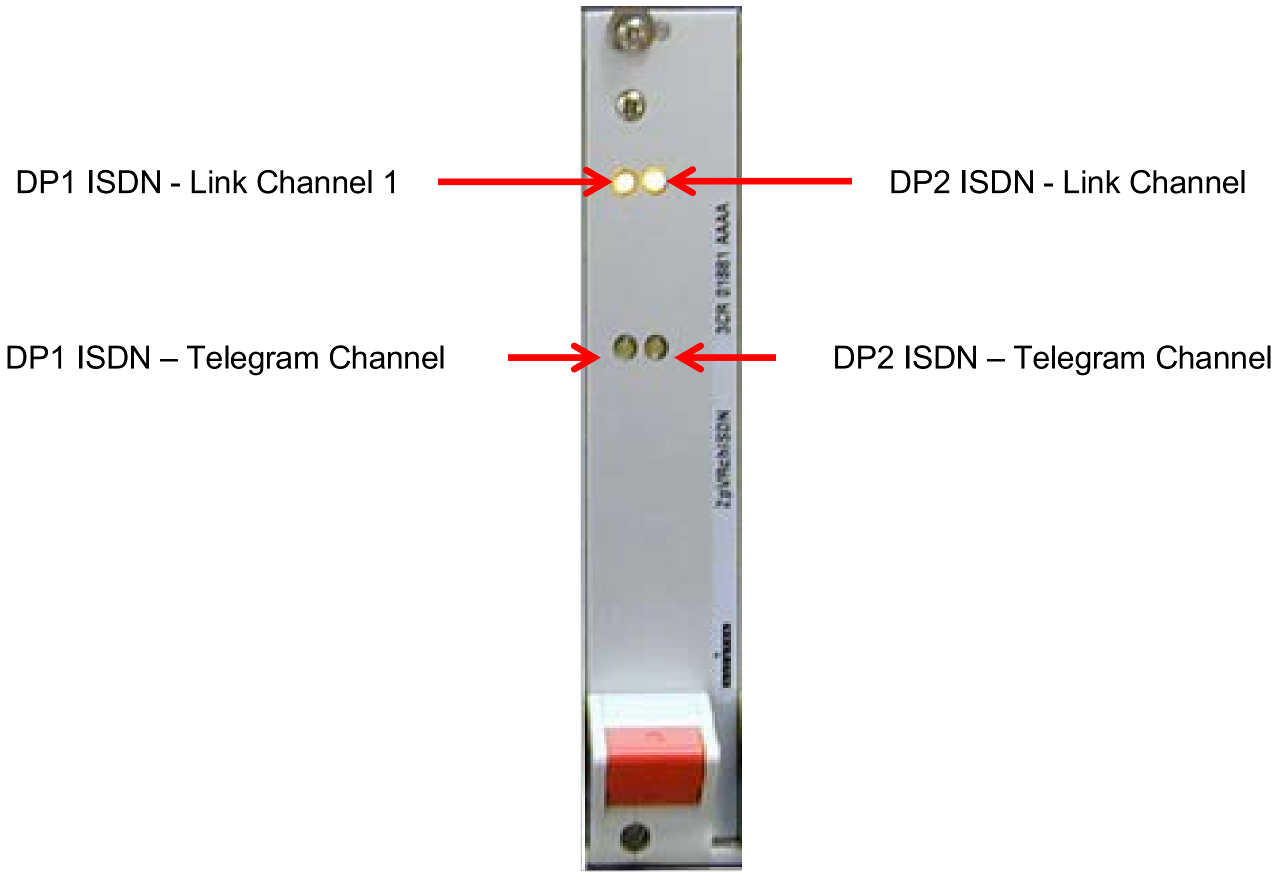

Figure 14

LED	Colour	State	Meaning
DP1 ISDN - Link Channel	**Yellow**	Extinguished	No ISDN link from Zp
		Illuminated	ISDN link operational
DP2 ISDN - Link Channel	**Yellow**	Extinguished	No ISDN link from Zp
		Illuminated	ISDN link operational
DP1 ISDN – Telegram Channel	**Yellow**	Illuminated / Extinguished	No valid telegram from Zp
		Pulsing	Valid telegram from Zp
DP2 ISDN – Telegram Channel	**Yellow**	Illuminated / Extinguished	No valid telegram from Zp
		Pulsing	Valid telegram from Zp

15. LED Indications : Evaluator Parallel I/O Card

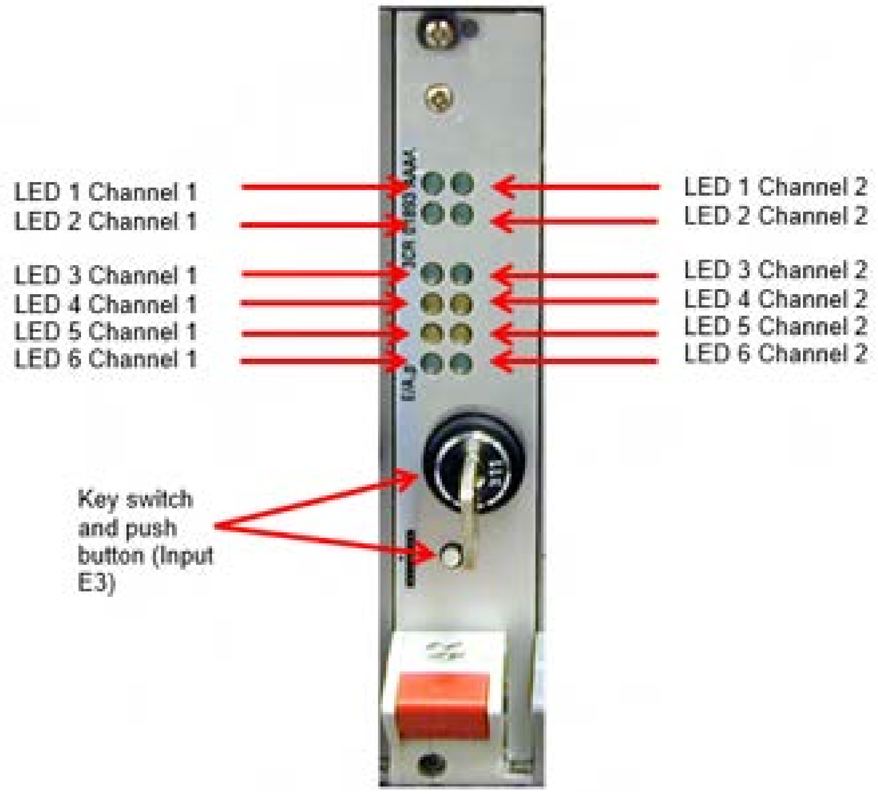

Figure 15

LED	Channel	Colour	State	Meaning
1	1 + 2	**Green**	Extinguished	External Input 1 not active
			Illuminated	External Input 1 active
2	1 + 2	**Green**	Extinguished	External Input 2 not active
			Illuminated	External Input 2 active
3	1 + 2	**Green**	Extinguished	Associated section is occupied
			Illuminated	Associated section is clear
4	1	**Yellow**	Illuminated	Non Vital Output 1 Energised
	2	**Yellow**	Illuminated	Non Vital Output 2 Energised
5	1	**Yellow**	Illuminated	Non Vital Output 3 Energised
	2	**Yellow**	Illuminated	Non Vital Output 4 Energised
6	1 + 2	**Yellow**	Illuminated/ Extinguished	Incorrect Polling of Input/Output
			Polling	Correct Polling of Input/Output

On earlier cards (V1.0.3) the only difference is rows 5 and 6, row 5 is polling and row 6 when illuminated indicates that the key switch and push button is active, its normal state should be extinguished.

Key switch/push button E3 can be configured as external input 3. The use of the function is controlled via Local Instruction. Interference with this key switch/button can cause locking of the inputs/outputs of the parallel card.

LED Indications: ACE DC to DC Power Cards

There are variants of this card in use at his time.

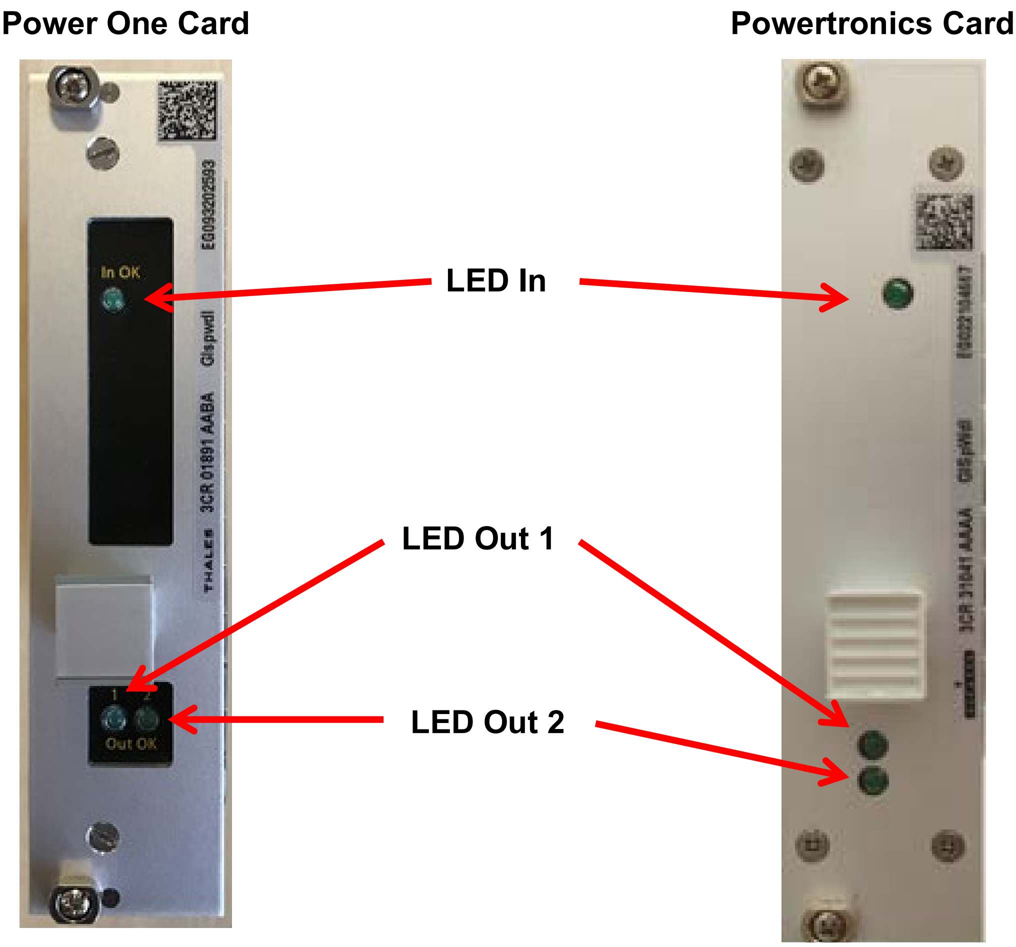

Figure 16

LED In	LED Out 1	LED Out 2	Function
Green	**Green**	**Green**	Normal Operation
Green	**Off**	**Green**	Temperature too high, over-load, over voltage output 1 or under voltage output 1
Green	**Green**	**Off**	Temperature too high, over-load, over voltage output 2/3 or under voltage output 2/3
Off	**Green**	**Green**	Not possible or “LED In” has failed
Off	**Off**	**Off**	No input voltage, input voltage too low, input open/high or voltage too high

If the PowerOne version of the DC/DC converter card is used it should be supplier version V106 or greater.

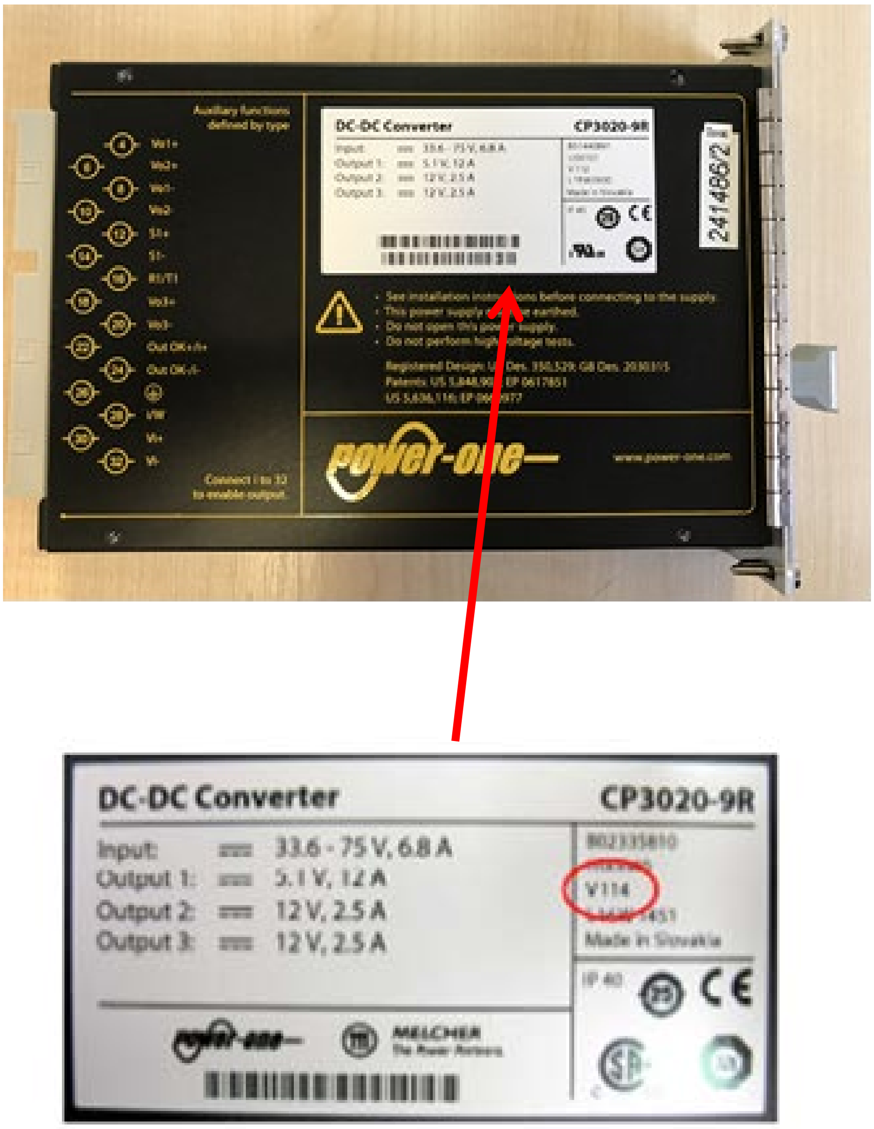

Figure 17

16. LED Indications: Evaluator CPU Cards (EP & EPCM Type)

EPCM CPU Card

EP CPU Card

Figure 18

Indication	Colour	State	Meaning
Alphanumeric Display	**Red**	Frozen bar	No CPU activity or CPU starting up
		*	
		Blank	
		Rotating bar	Correct CPU activity

Connectivity LED’s		
LED	**Colour**	**Meaning**
1		There is communication via the Ethernet Port
2		There is internal communication between CPU’s
3		There is internal communication between CPU’s
4		Thales use only

17. Single Channel Controller (SCC)

This board has been introduced due the obsolescence of the current EP (Embedded Pentium) & EPCM (Embedded Pentium Celeron Mobile) CPU's.

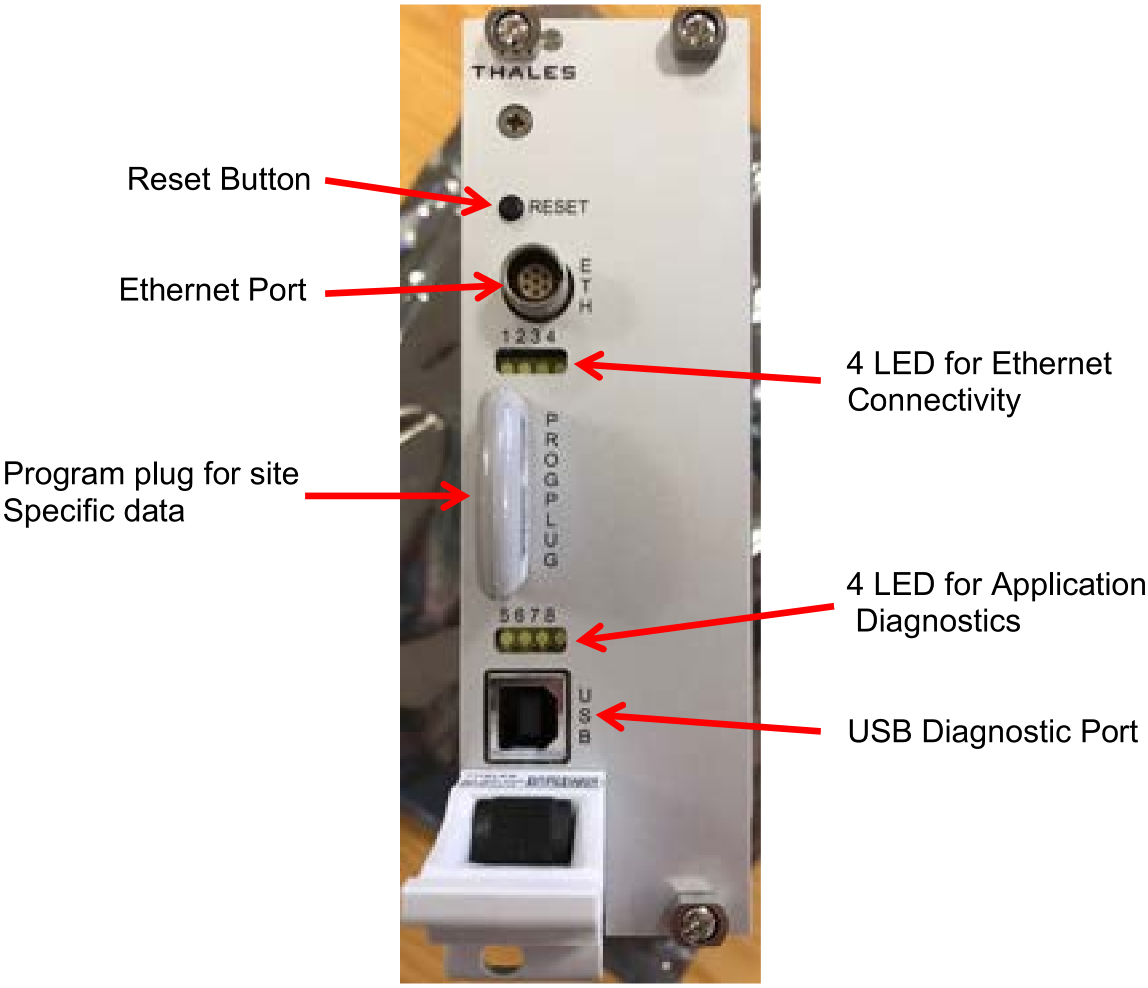

Figure 19

Connectivity LED's		
LED	**Colour**	**Meaning**
1		There is communication via the Ethernet Port
2		There is internal communication between CPU's
3		There is internal communication between CPU's
4		Thales use only
Diagnostic LED's		
LED	**Colour**	**Meaning**
5		These are polling LED's these indicate normal operation
6		
7		
8		

18. CPU Compatibility

There are four different types of CPU for the AzLM ACE:-

a) EP – (Embedded Pentium) Rev 1 (Commonly known as Rev A).
b) EP – (Embedded Pentium) Rev 2 (Commonly known as Rev B).
c) EPCM – (Embedded Pentium Celeron Mobile).
d) SCC – Single Chanel Controller.

These are to be installed in an ACE in pairs and are not mix and match. If CPU 2 only needs to be replaced it should be replaced with the same part number and rev / version number above. If this is not possible both CPUs should be replaced.

EP and EPCM CPUs use the serial connection of CPU 1 or Ethernet port of CPU2. The SCC board uses the USB on CPU 1 and Ethernet port of CPU2.

There are now three types of 128mb compact flash card, WD, Silicon Drive and Swissbit. WD and silicon drive and be mixed and matched in once ace.

19. Flash Cards Compatibility

Figure 20 – Swissbit Compact Flash Cards

Figure 21 – WD & Silicon Drive Compact Flash Cards

<u>Swissbit Type</u>

Swissbit can't be used with WD and silicon drive.

Swissbit cards can only be used by EPCM boards. For ACE's with Swissbit cards only EPCM CPU's can be used.

<u>WD (Western Digital) & Silicon Drive Types</u>

EP Rev 1, EP Rev 2 & EPCM can all use WD and Silicon drive.

	WD (Western Digital)	Silicone Drive	Swissbit
EP Rev 1	YES	YES	NO
EP Rev 2	YES	YES	NO
EPCM	YES	YES	YES
SCC	NO	NO	NO

Table – Compact Flash Card : Compatibility Matrix

<u>Program Plug Type</u>

SCC CPU uses a program plug and not a compact flash card. If the CPU needs to be changed from a EP Rev 1, EP Rev 2 & EPCM to SCC the data will need to be transferred from the compact flash card to the program plug and this must be completed by Thales.

20. Converter ISDN Ethernet (CIE) Card

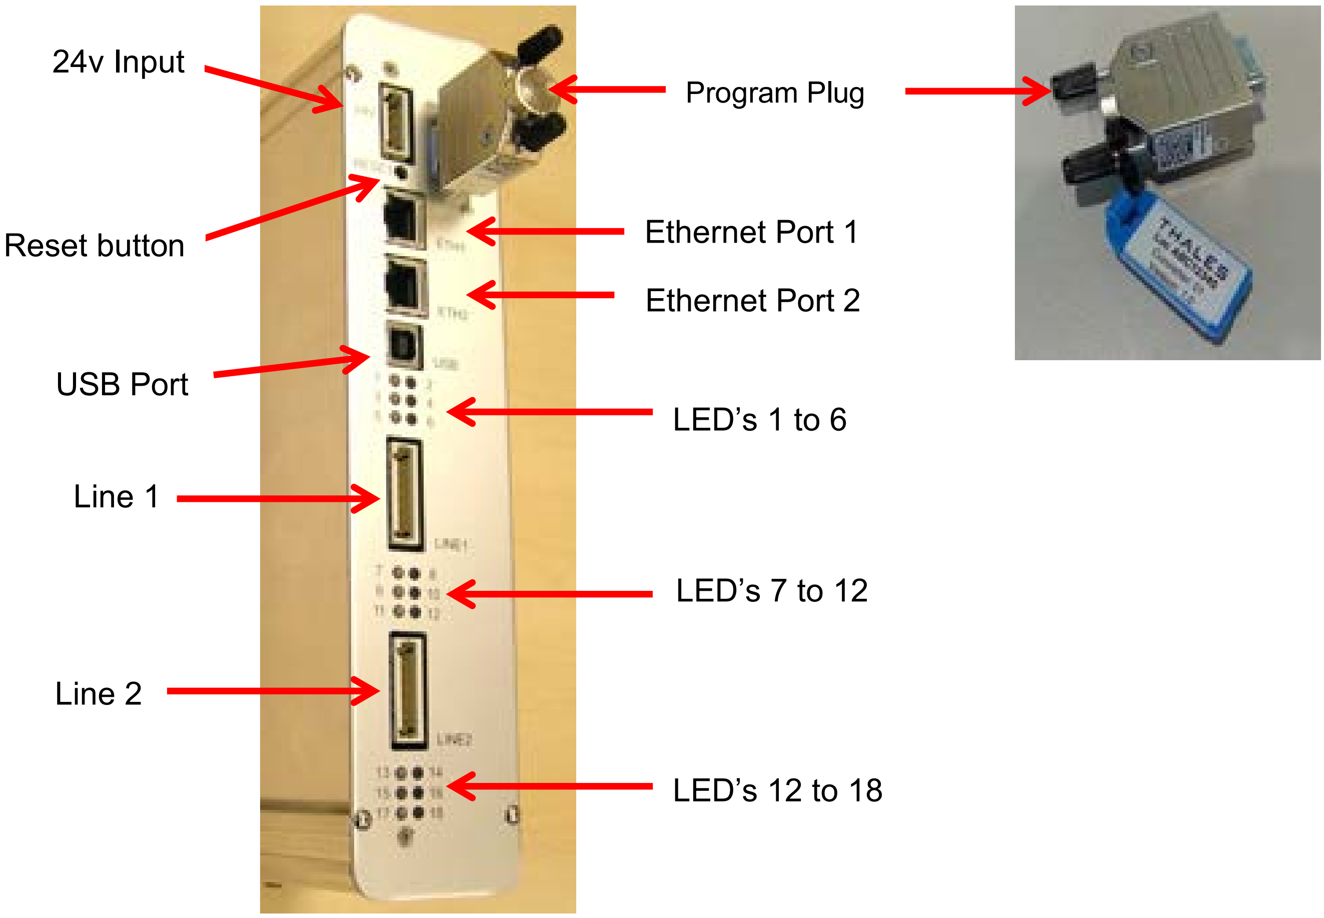

Figure 22

LED	Meaning	Normal Operation
1	Life signal CPU	**Green LED toggles** every second
2	Life signal CPU	**Yellow LED toggles** every second
3	PIC trigger	**Yellow LED toggles** every second
4	Not used	**Off**
5	24V redundant	**Green LED on**: Connected to 2 power supplies
6	24V non-redundant	**Off**: 24 V redundant available, LED 5 on.
7	Modem 1	**Green LED toggles** (every 200 ms) with each received correct telegram from modem 1 / 2.
8	Modem 2	
9	Not used	**Off**
10	DIP-Switches	**Off**
11	Line 1	**Green LED on**: ISDN connection modem 1 ok
12	Line 2	**Green LED on**: ISDN connection modem 2 ok
13	Fuse 1	**Off**
14	Fuse 1	**Red LED on**: Fuse Line 1 defect
15	Not used	**Off**
16	Not used	**Off**
17	Fuse 2	**Off**
18	Fuse 2	**Red LED on**: Fuse Line 2 defect

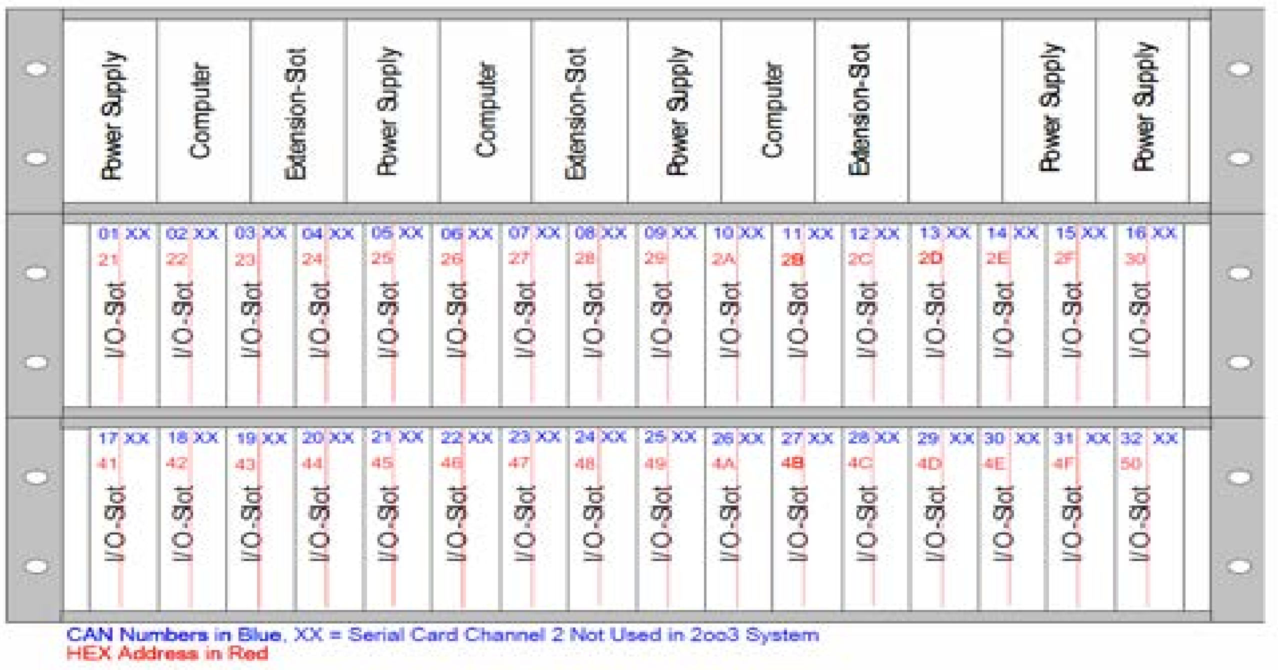

Figure 25

END

GENERAL

Harmon Crossing Processor

Figure 1 – The Harmon Crossing Processor (HXP) is a microprocessor based level crossing control system. Various models are available, however, only the HXP-3R and HXP-3R2 are currently in use on Network Rail infrastructure.

The '3' in the identity relates to these systems being from the Series 3 of the HXP systems – previous generations have been used in the United States – whilst the 'R' indicates that hardware redundancy is inherent within the units through the use of 'normal' and 'standby' systems.

The HXP-3R level crossing control system is able to control a level crossing on a single line. It should be thought of as being formed from two distinct parts, whilst the HXP-3R2 is able to control a level crossing on a double line railway. The HXP-3 comprises of either one (HXP-3R) or two (HXP-3R2) cabinets within which a series of modules, as described below, are contained.

Some modules are installed into predetermined slots within the cabinet and all modules shall be installed with the component side facing to the left.

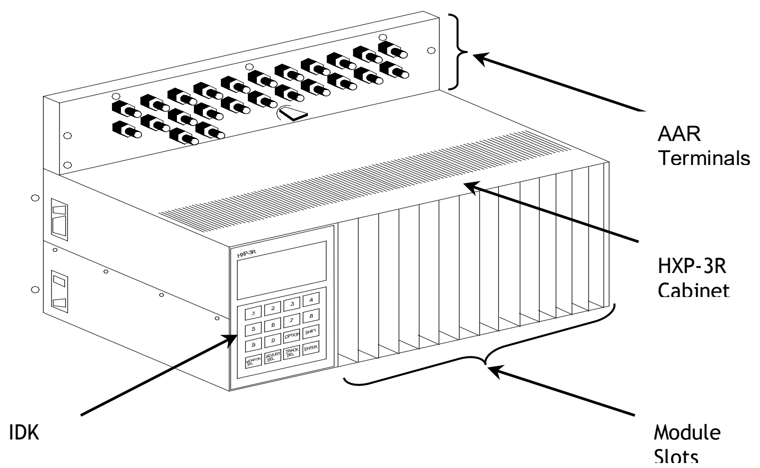

Figure 1 – HXP-3R

Central Processor Unit

The Central Processor Unit (CPU) controls the functions of the HXP-3. Both RAM and ROM memory for the system are located on this module along with non-volatile RAM for storing location specific parameters. Two CPU Modules (Normal and Standby) are installed next to each other in the HXP-3, the second acting as a backup for the first.

Serial Interface Module

The Serial Interface Module (SIM) is required to provide an interface between the HXP-3 and the Information Display Keypad (IDK). Its functions are controlled by a microprocessor located on the module. The SIM's memory is contained in Static RAM and can be accessed by microprocessors on either the CPU or the SIM. Two SIM Modules (Normal and Standby) are installed next to each other in the HXP-3, the second acting as a backup for the first.

Relay Driver Module

The Relay Driver Module (RYD) generates and controls the Motion Detector Relay Drive voltage, which is the main output of the HXP-3. System parameters are stored in Non-Volatile RAM located on this module. The module contains a power supply used to drive the HXP-3 circuits. Two RYD Modules (Normal and Standby) are installed next to each other in the HXP-3, the second acting as a backup for the first.

Transmitter Receiver Module

The Transmitter Receiver Module (TRM) serves as the Track transmitter and receiver for the HXP-3. Each track requires Two TRMs, one Normal and one Standby, to be installed into the HXP-3.

Random Signature Island Module

The Random Signature Island (RSI) Module provides Island relay control without requiring the selection of different operating frequencies. It contains a microprocessor, which triggers the transmitter to generate bursts of energy. These bursts of energy are of random frequency and duration in order to create a signature that can be selectively identified by the receiver, which monitors for the return of each signature. This allows the RSI to maintain Island operation without requiring different frequencies at adjacent Islands. The HXP-3 requires two RSI modules for each line of track present, the second acting as a backup for the first.

Transfer Logic Module

The Transfer Logic Module (TLM) monitors the Island transmitter and receiver currents along with the Island Relay Drive output and the MDR Drive output. If a fault is detected, the TLM transfers operation to the redundant system. All the power fuses in the HXP-3 are located on the TLM.

One TLM shall be installed in all HXP-3 cabinets.

Recorder Memory Module

The Recorder Memory Module (RMM) is used to record internal and external events and a clock is located on this module for time stamping these events.

Information Display Keypad

The Information Display Keypad (IDK), which plugs into the SIM and is secured to the front of the cabinet, is used to enter location parameters and to display system information. The module is made up of a Liquid Crystal Display (LCD) and 16 key keypad that interfaces with the HXP-3 via the SIM.

Auxiliary Relay Drive Module

The Auxiliary Relay Drive Module (AXD) is only present on HXP-3R2 models and has three identical AX Relay Drive outputs for adjacent crossing control or for traffic pre-emption. Each of these outputs can be programmed through the CPU Module. Where AXDs are used on HXP-3R2 equipment, two modules (Normal and Standby) are installed side by side, the second acting as a backup for the first.

End

Includes:	Siemens TRAINGUARD FUTUR 2500 Radio Block Centre (RBC) Cubicle
Exclude:	All other type of RBC/RBC Cubicles

GENERAL

The integrated RBC system is housed in a cubicle with all the associated equipment.

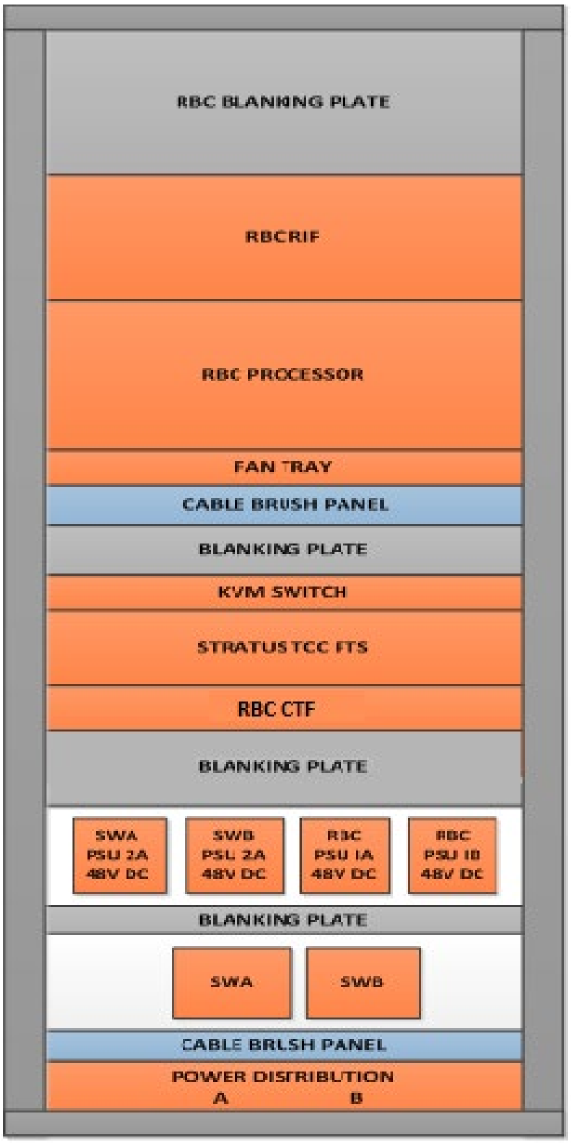

Figure 1 - RBC Cubicle

The TRAINGUARD FUTUR 2500 RBC cubicle is composed of the following elements:

Control Elements:

a) 1 RBC RIF

b) 1 RBC Processor MKII.

Cooling Elements:

a) 3 FAN Tray Modules (1 at the front; centre of the cubicle, 2 at the rear, one at the top, one at the bottom)

Maintenance Elements:

a) 1 KVM. The KVM is made up of:

- 1 KVM Switch
- 1 KVM Rack Console

b) 1 Keyboard

c) 1 PC Debug

d) 1 I/O Board for PC

e) 2 Converters from USB to Ethernet.

f) 1 PBA RBC CTRL

g) 1 Patch Panel

h) 1 GSM-R Stratus TCC FTS Element. This is made up of:

- 1 Server
- 2 ISDN Boards (The ISDN boards are housed in the server)

i) RBC Common Technicians Facility (CTF) – Blue Chip C110 PC

j) Dual Power Supply Unit (PSU) 48V

k) 2 Network Switches (SWITCH A and SWITCH B).

l) Dual Power Supply 110V AC PSUs – A and B supply for the RIF

RBC RIF:

The RBC-RIF is part of the WESTCAD-E architecture and is co-located in the RBC Cubicle and includes the Temporary Speed Restriction (TSR) functionality. The RBC-RIF will also handle the RBC arming process by passing indications to the Control Centre operator.

RBC Processor:

The RBC Processor is built on Ethernet IP Network (LAN/WAN). This provides flexibility to the system and an easy way to connect the RBC to other vital modules.

KVM Switch:

The ‘KVM Switch’ interconnects the TCC and the PC Debug with the ‘KVM Rack Console’ and the ‘Keyboard’.

GSM-R Stratus TCC FTS:

The GSM-R Stratus TCC FTS receives messages from the RBC Processor through the Ethernet interfaces and sends them to the train through the ISDN module.

In addition, it receives messages from the train through the ISDN modules and transmits these messages to the RBC Processor using the LAN network.

The Stratus TCC FTS is made up of:

a) 1 Stratus (server)

b) 2 ISDN Boards (The ISDN boards are housed in the server)

The Server is dual-redundant (CPU A and CPU B), and it is fault tolerant.

Each CPU has got an ISDN Board mounted. “ISDN A” is housed in “CPU A” and “ISDN B” is housed in CPU B.

Common Technicians Facility

This is a local technician’s workstation comprising of a Blue Chip C110 PC loaded with the CTF software. The local TF application is automatically executed when the PC is turned on. The CTF is a diagnostic tool that offers the user fault indications of the system, and replay functionality. The TF in this cubicle (RBC TF-L) is also linked to the RBC TF-S and RBC TF-R to allow remote access from Arch 886.

Power Supplies:

- A Dual Power supply Unit (48V) is provided to power the RBC RIF.
- A separate Dual Power supply (110V DC) is sourced from the signalling supply in LBER to provide power for the RBC Processor.

CISCO 16 Port Network Switches SWA and SWB:

The Cisco Catalyst is a COTS network switch. This connects with the RBC Cubicle at LBER and provides remote communication from TBROC over T-SPN (Thameslink Signalling Private Network).

Datalogger (Test tool)

A data-logger will be attached to the RBC via the Network Switches in the same cubicle. This is a test tool and no maintenance is needed to be provided.

END

Trainstops contain moving parts which can cause severe personal injury.

Equipment Replacement Guidance

1. Replacing a Trainstop (Complete)

The tools required for the following procedure are:

- JE Trainstop
- Common hand tools such as adjustable spanners;
- Approved mechanical lifting equipment with ability to lift 100 kg;
- Trainstop Trip Arm gauge;
- Open ended or ring spanners to suit fixings;
- 20W-50 engine oil;
- Steel measuring tape, ruler, scriber, square, centre punch, hammer;
- Two Packer Plates – can be supplied with the new Trainstops, or separately;
- Sole Plate

Removal

1.1 Keeping clear of the Trip Arm, isolate the supply from the Trainstop.

1.2 Disconnect the tail cables. Place the free end in a safe and dry place ensuring that the cable is not a trip hazard.

1.3 Disconnect the earth bonding cable from the Earth Connection Point on the exterior of the machine case.

1.4 Undo the four fixings securing the Trainstop to the bearers or Sole Plate.

1.5 Take note whether Packer Plates are fitted between the Trainstop and the bearer or Sole Plate.

1.6 Using appropriate lifting equipment, remove the Trainstop and put it in a safe place.

Replacement

1.7 Using appropriate lifting equipment, position the replacement Trainstop on the bearers, fitting Packer Plates if necessary.

1.8 Adjust the position of the Trainstop such that the distance from the inside of the running rail to the centre of the Trip Arm is 222 mm +/- 3 mm, with the body of the Trainstop parallel to the running rail.

1.9 Secure the Trainstop to the bearers using the original fixings (if these fixings are undamaged). If fixings are damaged, they must be replaced with serviceable items.

1.10 Connect the earth bonding cable to the Earth Connection Point on the exterior of the machine case.

1.11 With the Trip Arm in the raised position, use the Trainstop Trip Arm gauge to check that the top of the Trip Arm is 76 mm +/- 3 mm above a line joining the tops of the running rails (Figure 1).

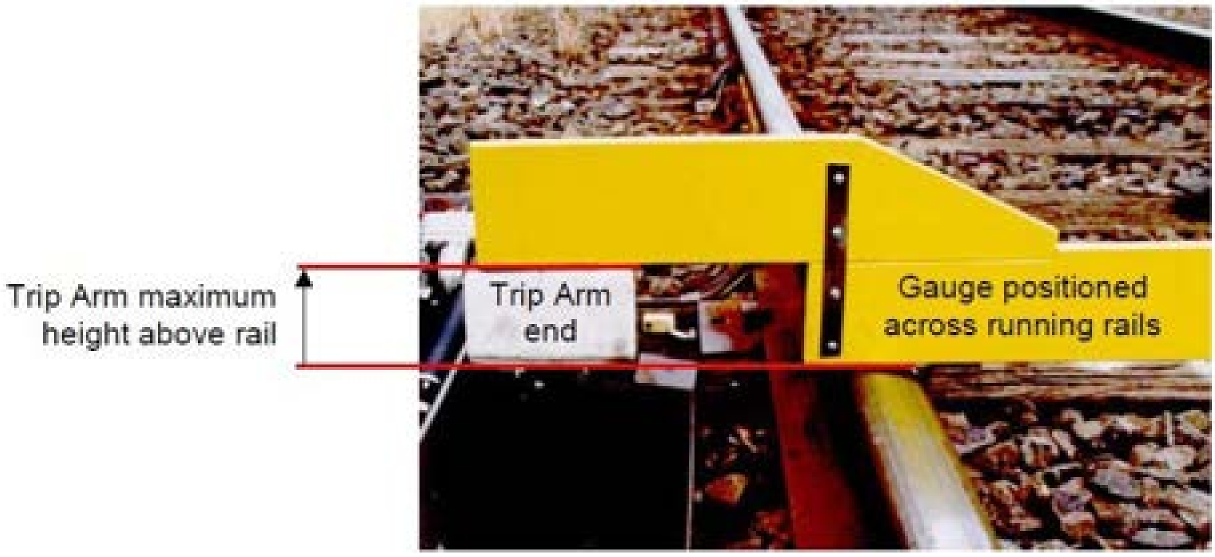

Figure 1 – Height of Trip Arm Checked with Gauge

1.12 Open the top cover of the Trainstop and check the oil level in the dashpot. Oil should be level with the mark on the outside of the dashpot (see Figure 2) when the Trip Arm is raised. If low, fill to the mark with 20W-50 engine oil.

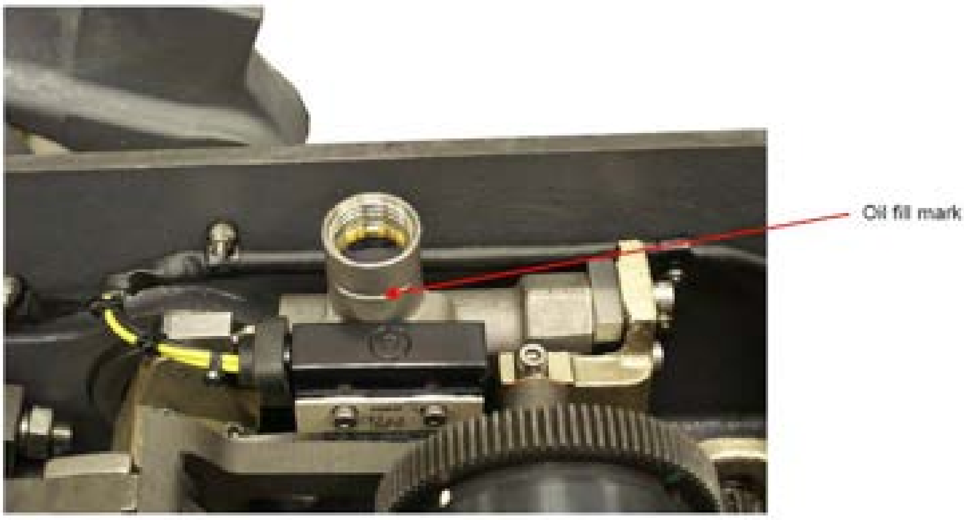

Figure 2 – Dashpot Oil Fill Mark

1.13 Check that the interior of the Trainstop is clear of any tools or equipment, then close and secure the top cover.

2. Replacing a Trainstop Trip Arm

The tools required for the following procedures are:

- Trip Arm Gauge;
- Ruler or steel measuring tape;
- Open ended spanners;
- Ring set spanners;
- Socket set;
- Spanners 24 mm AF;
- Trip Arm;

Removal

2.1 Check you are clear from the Trip Arm, isolate the supply and disconnect the tail cables.

Note the assembly order (base of Trip Arm) – this is for the securing bolt and associated washer, see Figure 3.

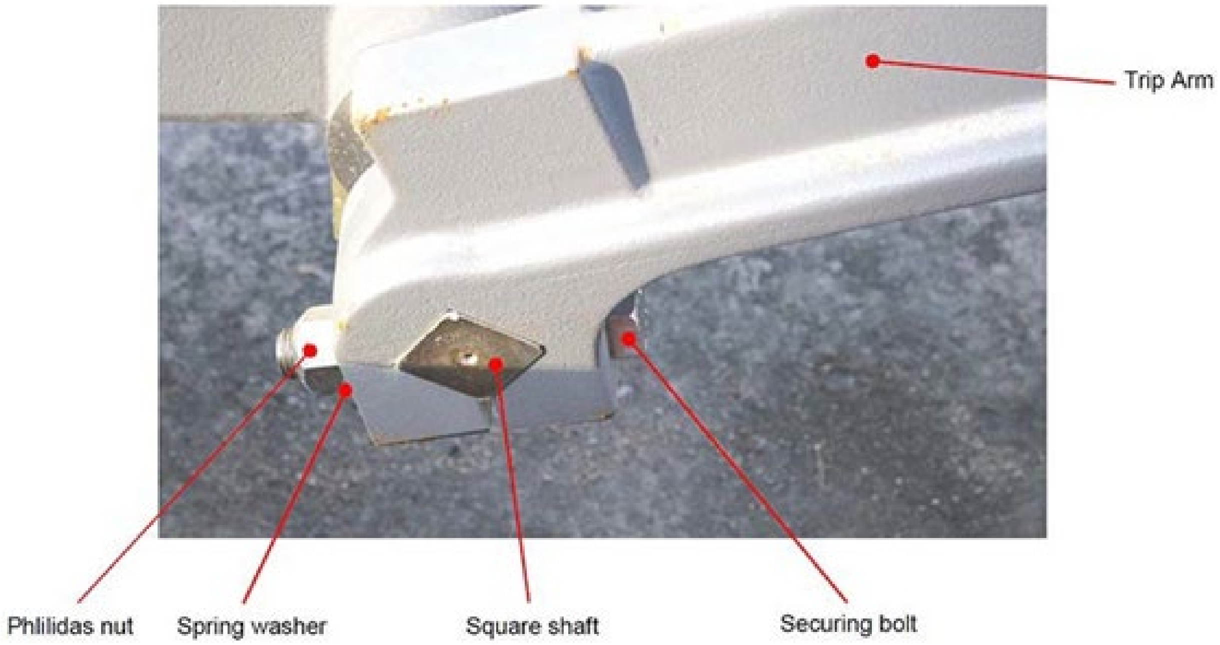

Figure 3 – Trip Arm Securing Bolt

2.2 Remove the securing bolt from the Trip Arm and slide the Trip Arm clear off the square shaft.

Note the assembly order of the shouldered stud fitted towards the top of the Trip Arm.

2.3 Remove the shouldered stud and retain for re-fitting the replacement Trip Arm.

Replacement

2.4 Fit the shouldered stud that was retained from the original Trip Arm.

2.5 Slide the Trip Arm fully onto the square shaft; ensure the shouldered stud engages with the Detector Arm, see, Figure 4.

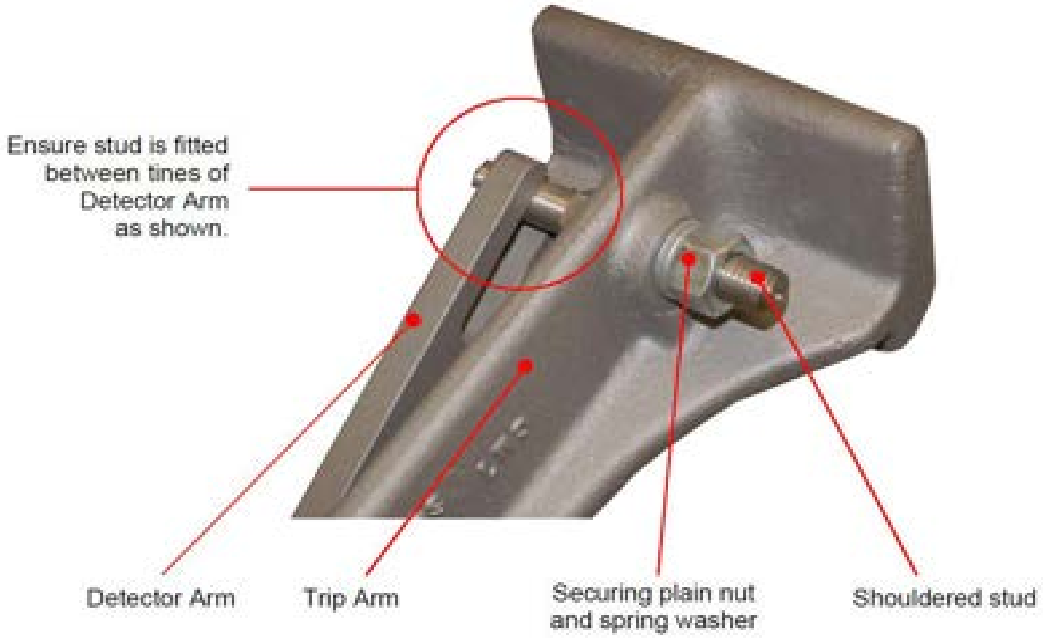

Figure 4 – Trip Arm Correctly Engaged with Detector Arm

2.6 Fit the securing bolt, spring washer and Philidas nut, shown in Figure 3.

2.7 Tighten the securing bolt fully and check that the Trip Arm if secure on the square shaft.

3. Replacing a Motor Assemble

The tools required for the following procedure are:

- Motor Assembly
- Two Nord-lock washers
- Philips cross-head screwdriver;
- Electrical screwdriver;
- Hex key 4 mm AF;

Removal

3.1 Check you are clear from the Trip Arm, isolate the supply and disconnect the tail cables.

3.2 Open the top cover to access the interior of the machine.

3.3 Identify the Rectifier Assembly and Motor Assembly (shown in Figure 5).

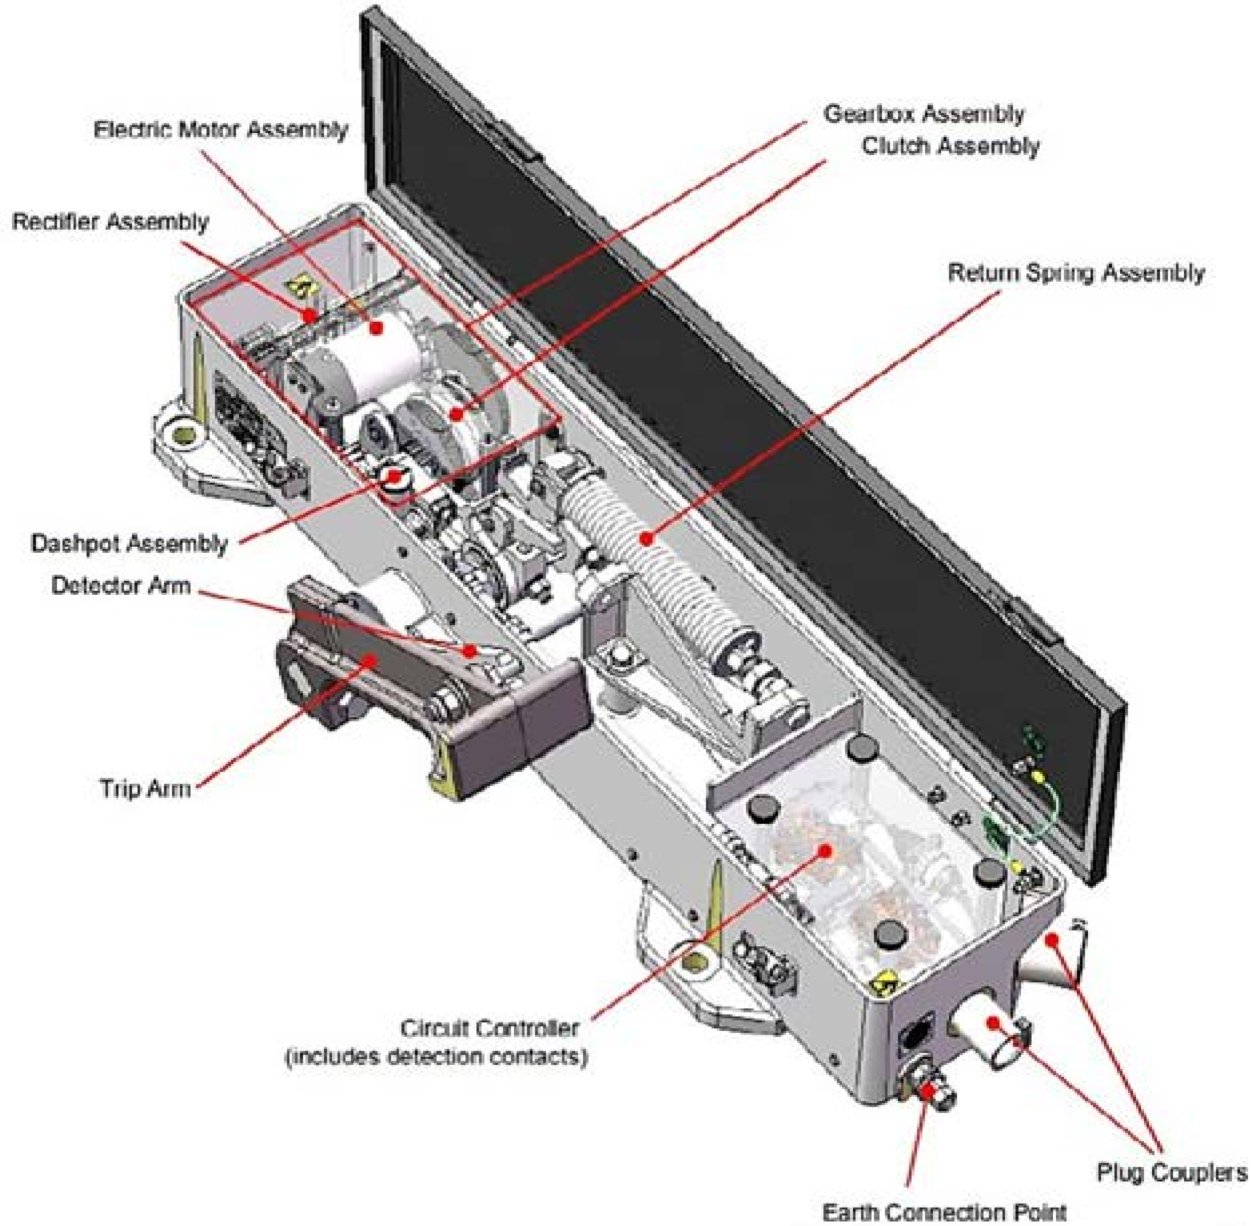

Figure 5 – Style JE Trainstop Main Assemblies

3.4 At the Rectifier Assembly, unscrew the cover fixings and remove the transparent cover.

3.5 Retain cover and fixings for re-use.

3.6 At the Motor Assembly, remove the two mounting plate securing screws (hex socket headed) and associated washers (shown in Figure 6).

3.7 Retain the screws for re-use and discard the washers.

3.8 Lift the Motor and Mounting Plate clear of its mounting and trace the motor supply cable to the terminal block. Take note of the positions of the motor wires in the terminal block.

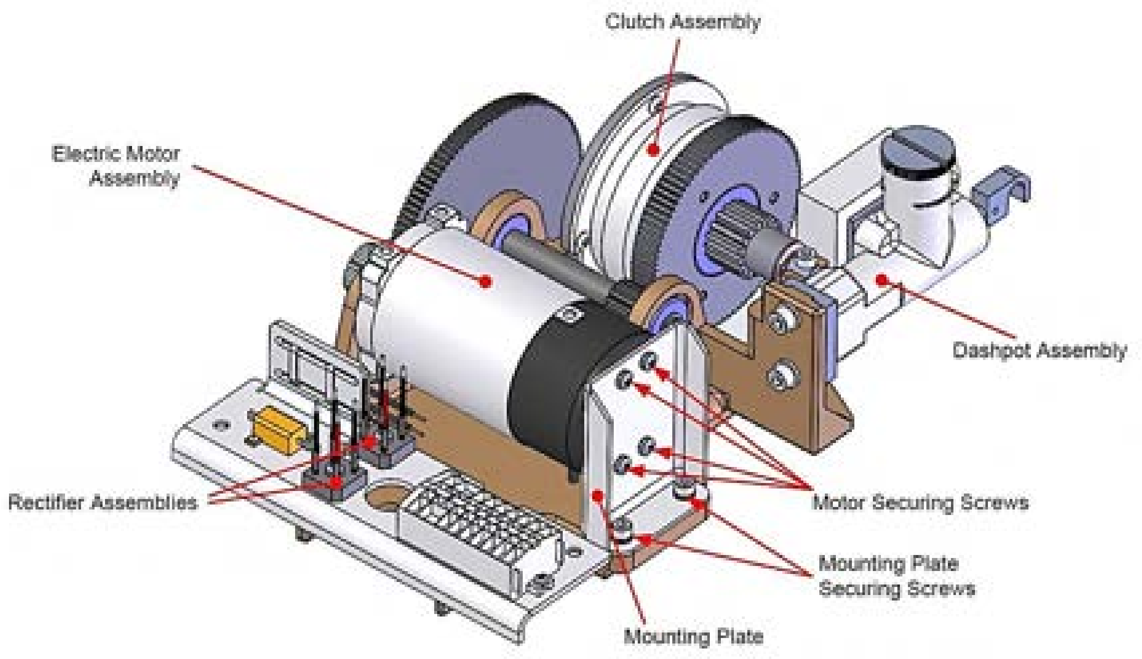

Figure 6 – Gear Box Assembly

3.9 Disconnect the motor wires from the terminal block and remove the Motor Assembly from the Trainstop.

3.10 At the Motor Assembly, remove the four motor securing screws and associated washers (shown in Figure 6). Retain the screws, washers and Mounting Plate for re-use.

Replacement

3.11 Fit the mounting plate on the replacement motor assembly and secure using the four motor securing screws and associated washers (shown in Figure 6).

3.12 Fit the replacement motor and mounting plate into the Trainstop, laying the motor supply cable towards the terminal block. Take care not to trap the motor supply cable.

3.13 Secure the motor assembly by re-fitting the two mounting plate securing screws and two new Nord-lock washers (shown in Figure 6).

3.14 At the terminal block, connect the motor wires in the positions previously noted (Terminal 4 +ve red wire, Terminal 5 -ve blue wire).

3.15 Re-fit the transparent cover over the Rectifier Assembly.

3.16 Close and secure the Trainstop top cover.

End

SYSTEM OVERVIEW

1. Advanced Railway Automation Management and Information System (ARAMIS)

ARAMIS is a sophisticated Rail Traffic Management System which supports planning, supervision, dispatch, control and analysis of train services.

The system has a modular architecture allowing it to be scaled to suit specific customer requirements.

ARAMIS is a Software Product which can be deployed on any suitably designed hardware platform that meets its hardware requirements. The system is configured to its specific installation by data.

The following sections will provide an introduction to the hardware and software elements of the ARAMIS system, and its interfaces.

2. Hardware Components

All the serviceable ARAMIS hardware components are defined as Line Replaceable Units (LRUs).

3. Software Sub-systems

3.1 ARAMIS-D

ARAMIS-D is the primary system within the Plan / Re-Plan layer, and is responsible for near to real-time train planning.

Note, ARAMIS-A is also a function of ARAMIS-D (accessed via the ARAMIS-D menu) that enables the production of analytical reports on the running of the railway, based on data that was collated within ARAMIS-D.

Note: Client HMI is also referred, this is Graphical User Interface (GUI) which is integral to the system, allowing users to access functions of ARAMIS-D

3.2 ARAMIS-W

ARAMIS-W is a web server application that takes a real time read-only feed of data from ARAMIS-D to enable it to present a subset of ARAMIS-D features to ‘remote’ authenticated users.

Such users access the functions provided through Microsoft Explorer browser clients. These are provided and maintained by NR and therefore not covered by this manual.

4. Thales Integration Layer (TIL)

The Thales Integration Layer (TIL) is the generic reference for a collection of components that provide a messaging abstraction layer between ARAMIS-D and the UK focused systems that lie within the External Layer.

5. Maintenance Terminal

The maintenance terminal provides the tools the maintainer needs to undertake the monitoring, log management and Virtual Machine (VM) management tasks. It provides access to the Nagios application for monitoring, the common storage VM for log management and VMware for VM management.

6. Operation Decision Support Tool (ODST)

ARAMIS Traffic Management has been deployed in the ODST configuration for both Wales and Anglia Routes. An ODST system is integrated with Network Rails conventional systems via LINX but is isolated from signalling control. ARAMIS is used as a plan; re-plan tool and the recommendations are then actioned on the control system.

This manual focusses on the sub-systems below the cut-line, known as the ‘Plan/Re-Plan Layer’ which is performed by the ARAMIS System.

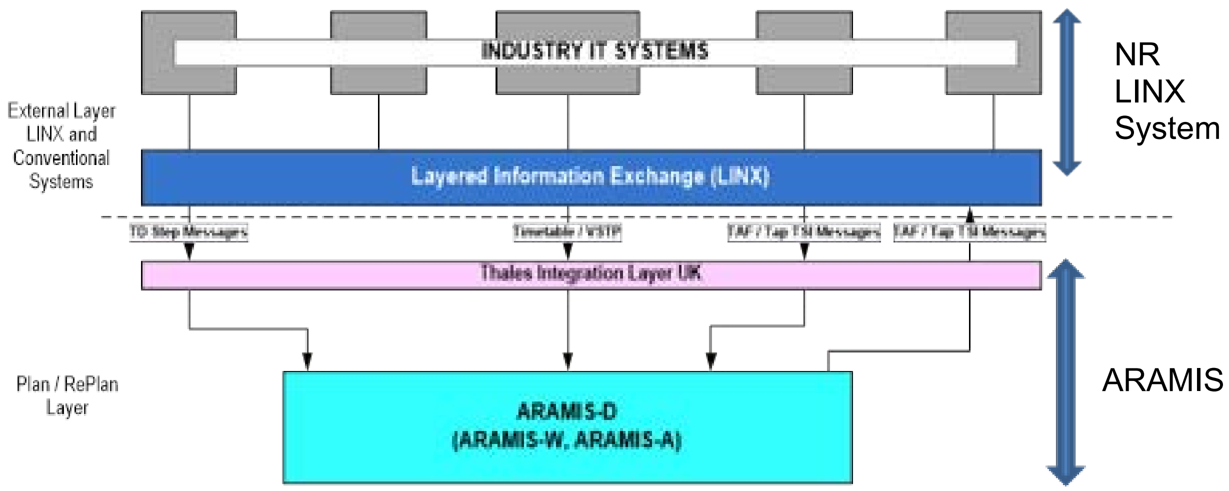

Figure 1 - ODST High Level Summary Schematic of the ODST Architecture

7. Interfaces

ARAMIS interfaces with Network Rail’s Layered INformation eXchange (LINX) system via the TIL. This is an inter-system message broker based on IBM Message Queue (MQ) and File Transfer Protocol (FTP) technologies.

LINX enables ARAMIS to communicate with conventional NR systems such as Integrated Train Planning System (ITPS) and Train Running Under System TOPS (TRUST).

From these systems ARAMIS receives dynamic railway data including Train Describer Step messages, Timetable messages and Telematics Applications for Passenger services (TAP) / Telematics applications for Freight services (TAF) messages.

Communication from the ARAMIS system to LINX and the ARAMIS-W clients is provided by services from Network Rail Telecoms (NRT).

Also, in Anglia, connectivity between Upminster and Romford is provided by NRT services.

The NRT services in the Rail Operating Centre (ROC) are provided by firewalls and a range of switches. The NRT demarcation point between Thales and NRT is the NRT 'Meet Me' rack.

Thales systems are patched into this rack as are NRT systems and a patch is then made between the two end points.

Maintenance of the 'Meet Me' rack is undertaken by Network Rail Telecoms.

8. Power Distribution

8.1 ARAMIS Workstation

- A primary 110Vac Uninterrupted Power Supply (UPS) A - Supplies ARAMIS monitors and Kernel Virtual Machine (KVM) via 110V AC Power Distribution Unit (PDU) mounted in the 19inch equipment rack under the desk.
- A secondary 110Vac UPS B supply – For future provision only.

8.2 ARAMIS Cubicle

The ARAMIS cubicles will be powered via two 230v AC PDU strips providing dual-redundant power to the equipment in the cubicle. These will be fed from separate PDUs within the Equipment Room.

This enables the E&P maintainer to turn off and maintain a single supply without impacting ARAMIS it there are no existing power supply faults.

9. Data Cabling

9.1 Above Workstation Surface Level

ARAMIS monitors are connected via Display Port Cables to the Amulet KVM located in cabinets below the workstation surface.

ARAMIS Keyboard and Mouse are connected to the Amulet KVM via USB cables, typically located in cabinets below the workstation surface.

9.2 Below Workstation Level Wales

From the ARAMIS cabinets under the workstation; the Amulet KVM are wired to a Fibre Optic Patch Panel using a 2-core Multimode Fibre cable.

A ruggedised 2-core Multimode Fibre cables are used to connect the Fibre Optic Patch Panel from the workstations, to another Fibre Optic Patch Panel housed in the main equipment rack for patching to the Client Personal Computer (PC).

10. Below Workstation Level Upminster

From the ARAMIS cabinets under the workstation; the Amulet KVM are wired to a desktop machine in the Upminster under desk equipment cabinet.

11. System Maintenance Features

The ARAMIS hardware platform has been designed with simplicity, availability and reliability in mind.

ARAMIS uses COTS components utilising the best of Information Technology (IT) design such as the use of redundancy, VMWare, Storage Area Networks (SAN), blade servers and Redundant Array of Independent Disks (RAID) disks for incremental/differential back-ups. The hardware platform features:

11.1 Dual redundant Hot Swappable Components

The servers provided by Thales are high quality industrial servers that incorporate redundant, hot swappable power supplies, fans and disks.

It is possible to hot swap all these hardware components without powering down.

For example, even a faulty disk can be removed without powering down, and a replacement disk inserted.

The new disk will be re-built by the system using RAID technology with minimal intervention required by the Maintainer.

11.2 Self-monitoring Servers

The servers are monitored by the Manufacturer’s Server Management Facility that provides an intuitive monitoring and reporting system.

This will report errors when they occur and present them as status indications against physical representations of the equipment impacted.

No sophisticated analysis of log files or error messages is required.

The Network Rail Maintainer can get an overview of the system status from the Nagios based monitoring system.

11.3 Use of Virtual Machines

The system requires multiple servers to host ARAMIS, Oracle data bases and other software components that make up the TMS as a whole.

However, the use of virtual machines enables these applications to be hosted on the same physical hardware, increasing the reliability by reducing the number of hardware components and associated communications infrastructure that would be required by stand-alone servers.

11.4 Use of Virtual Machines and Disk Images

The combination of virtual machines and the ability to take disk images of the virtual machine, and its hosted operating system and applications enables the complete server software architecture to be stored in one file.

This greatly eases configuration, loading and control of the system avoiding the need for the Maintainer to know the structure and configuration of the hosted software.

11.5 Pre-configured Spares

All agreed spares provided for the system will be fully pre-configured and ready to use, facilitating as far as possible, the ability to plug and play with as little post-installation configuration as possible.

12. Maintenance Mode

12.1 Placing a Server into Maintenance Mode

A server that is experiencing performance issues can have a negative impact on the system as VMware will be continually moving virtual machines between resources.

This can be addressed by exploiting the built-in redundancy of the system and placing the problematic server into maintenance mode to restrict it from use by VMware.

The redundancy within the system allows for three servers to be placed into maintenance mode before there are any performance 19impacts.

However, problematic servers should be repaired or replaced as soon as an issue is identified to guarantee the availability of ARAMIS is maintained.

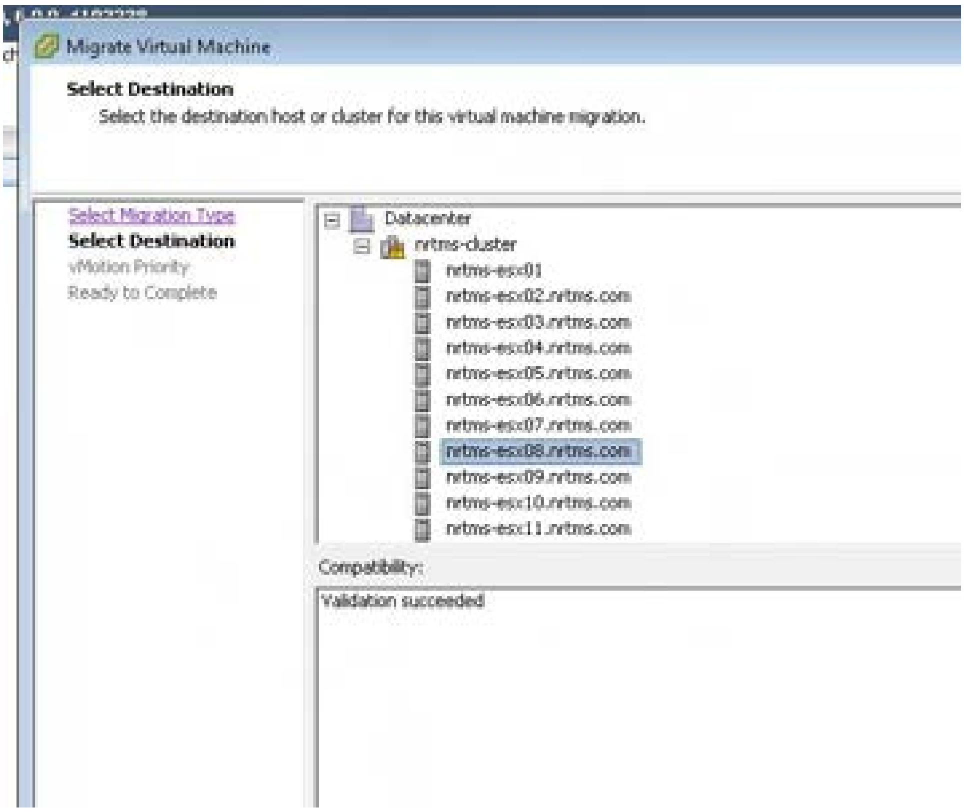
All instances of placing a server into maintenance mode should be reported to the Thales Service Centre.

The following steps should be completed to restrict a server from use by VMware:

1. Select the failed server from the list of servers.

2. For each VM on that server, right click and select migrate.

3. Select another available server to migrate the VM to.



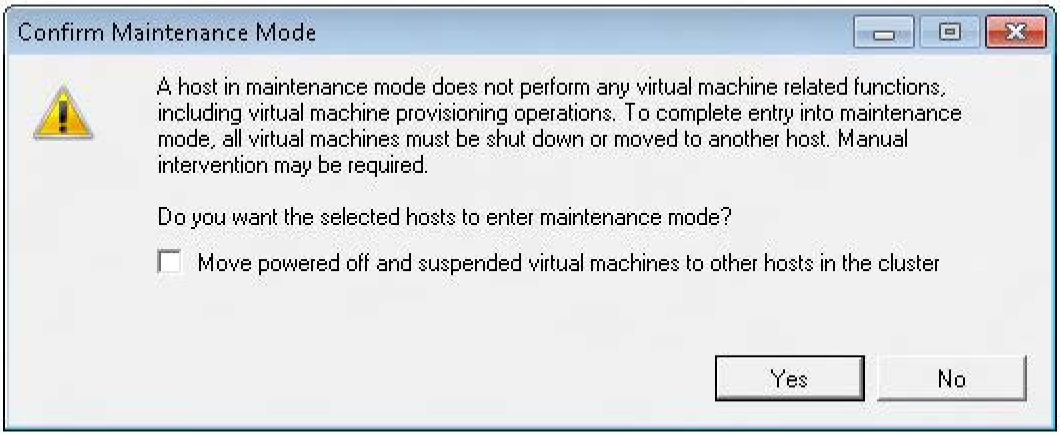
4. Once migration of VM is complete, select High Priority from the dialogue.

5. Click Finish.

6. Repeat steps 2 – 5 for all remaining VMs.

7. Right click on failed server which now has no active VMs running on it. Select enter maintenance mode.

8. Deselect the check box regarding VM allocation on the dialogue as this has been manually achieved in the steps above.



9. The failed server should now be identified in the list as being in maintenance mode.

13. System Hardware Components 2nd Line Maintenance Responsibilities

The table 1 lists the ARAMIS hardware LRU components and describes their 2nd Line maintenance responsibilities in accordance with the maintenance philosophy.

ARAMIS Hardware Components	Hardware Sub-Components	Hardware Profile ANNEX Reference	2nd Line Maintenance Responsibility
Workstation Monitor - NEC Multisync EA273WMi	-	A1	Network Rail
Workstation Keyboard - Microsoft Wired Keyboard 600	-	A2	Network Rail
Workstation Mouse - Microsoft Basic Optical Mouse	-	A2	Network Rail
Zero Client – Amulet DXZ4-M	-	A3	Network Rail
Client PC - Dell Precision 7910 Rackmount	Workstation	A4	Thales
	Hard Disk Drive (SSD)	A4	Network Rail
	Fan	A4	Network Rail
	Power Supplies	A4	Network Rail
Virtual Server - Dell PowerEdge R530 Rackmount	Server	A5	Thales
	Hard Disk Drive (SD)	A5	Network Rail
	Fan	A5	Network Rail
	Power Supplies	A5	Network Rail
Maintenance Server - PowerEdge M620 Blade	Blade Servers	A6	Thales
	Hard Disk Drive	A6	Network Rail
	Fan	A6	Network Rail
	Power Supplies	A6	Network Rail
	10GB Network Interface Card	A6	Thales
Server Storage SAN - HP MSA 2040	2040 SAN	A7	Thales
	Hard Disk Drive	A7	Network Rail
	Power Supplies	A7	Network Rail
	HP MSA SAN Controller (Single Only)	A7	Network Rail
Network Core Switch - Cisco Nexus 5672UP	Core Switch	A8	Thales
	Power Supplies	A8	Network Rail
	Fan	A8	Network Rail
Network Access Switch - Cisco Catalyst 2960XR-24TS-I	Access Switch	A9	Thales
	Power Supplies (with in-built Fan)	A9	Network Rail
Network Management Switch - Cisco Catalyst 2960XR-48TS-I	Management Switch	A10	Thales
	Power Supplies (with built in Fan)	A10	Network Rail
Firewall - CISCO ASA 5545-X WITH FIRE POWER Services	Firewall	A11	Thales
	PSU	A11	Network Rail
	HDD (single only)	A11	Network Rail
Server HMI - KVM Rackmount Console Unicorn 17	-	A12	Network Rail
Maintenance Terminal – Dell Latitude E5570 Laptop	-	A13	Thales

Table 1 - ARAMIS hardware LRU components

14. Acronyms and Abbreviations

Term	Description
ARAMIS ODST	Advanced Railway Automation Management & Information System Includes ARAMIS-A / ARAMIS-D, ARAMIS-W and ARAMIS-TIL products.
ATS	Automatic Transfer Switch
CATS	Course A Training System
CCTV	Closed-Circuit Television
CPC	Client PC
CPU	Central Processing Unit
ESXi	VMware ESXi is a purpose-built bare-metal hypervisor that installs directly onto a physical server.
FT	Fault Tolerant
Gbps	Gigabits per second
HA	High Availability
HMI	Human Machine Interface
iSCSI	Internet Small Computer System Interface
LAN	Local Area Network
LX	Level Crossing
M&S	Maintenance and Support
Mbps	Megabits per second
MSVR	Maintenance Server
MWS	Maintenance Laptop
NR	Network Rail
NRT	Network Rail Telecoms
NRTMS	Network Rail Traffic Management System
O&M	Operations and Maintenance
ODST	Operations Decision Support Tool
PC	Personal Computer
PCIe	Peripheral Component Interconnect Express
PCoIP	PC over Internet Protocol
PDU	Power Distribution Unit
PSU	Power Supply Unit
RAID	Redundant Array of Independent Disks
ROC	Rail Operating Centre
SAN	Storage Area Network
SATA	Serial AT Attachment
SCSI	Small Computer System Interface
SSD	Solid State Drive/Disk
SSM	Shift Signaller Manager

Term	Description
SWA	Access Switch
SWC	Core Switch
TAF	Telematic Applications for Freight
TAP	Telematic Application for Passenger
TRC	Train Running Controller
TRESIM	Simulator by The Rail Engineering Company
vCPU	virtual CPU
VM	Virtual Machine
vSAN	virtual Storage Area Network
USB	Universal Serial Bus

Table 2 – Acronyms and Abbreviations

15. Configuration of the Amulet

CONFIGURATION PROCESS

This process shall only be carried out by a competent person, if at any point during the process you are unsure of what you seeing or actions you should take you must immediately stop work and seek advice.

Establishing a PCoIP connection

15.1 After a short delay, the built-in On-Screen Display will be visible on the monitor connected to the port

NOTE: *The zero client can be configured to use DHCP or a static IP address. To change the settings in the On-Screen Display, open the Options menu (top left), click the Configurations item and then the Network tab. If required, the default password is ahkdante. Do not change the default password.*

15.2 Click the Connect button. The 'Discovering hosts' message will display, followed by a list of all available hosts.

NOTE: *The Connect button is greyed out until the DXZ4 has a network connection and an IP address. If no PCoIP hosts are available, the connect button will still work but, after trying and failing to discover any hosts, the 'No Hosts available for connection' message is displayed.*

Amulet Configuration

15.3 Plug in AMULET via Ethernet to a hub.

15.4 Plug in laptop to a hub, set IP to 192.168.1.10

15.5 Browse to IP 192.168.1.50

15.6 Login – password is “ahkdante”.

15.7 Change session to “Direct to Host”.

15.8 Set IP 192.168.1.100

15.9 Power – Set both timeout to 0 seconds.

Configuration -> Power

15.10 Set power configuration as follows:

- Screensaver, suspect, power off timeouts all 0.
- Remote host power control – off.
- Power on after power loss – checked.
- Enable wake on USB, Wake on LAN – checked.

Configuration -> USB -> Authorised devices

15.11 Set authorised device as follows:

VID	PID
045E	07F8
045E	00CB
04B4	6572

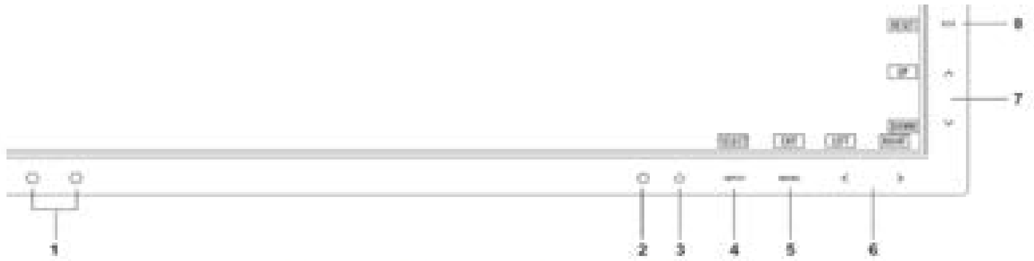
Select a PCoIP host from the list using the host IP address as a reference and click OK.

If the connection is successful, the Link LED displays constant green and the video from the remote workstation displays on the monitor(s).

16. Component Breakdown

16.1 Workstation Monitor - NEC Multisync EA273WMi

Front View



1 Ambibright Sensor Human Sensor	Detects the level of ambient lighting, allowing the monitor to make adjustments to various settings resulting in a more comfortable viewing experience. Do not cover this sensor.
2 LED	Indicates that the power is on or off.
3 Power	Turns the monitor on and off.
4 INPUT/SELECT	Enters the OSD Control menu. Enters OSD sub menus. Changes the input source when not in the OSD Control menu.
5 MENU/EXIT	Accesses OSD menu. Exits the OSD sub menu. Exits OSD Control menu.
6 LEFT/RIGHT	Navigates to the left or right through the OSD Control menu. You can adjust the BRIGHTNESS directly while the OSD menu is off*.
7 UP/DOWN	Navigates up or down through the OSD Control menu. You can adjust the VOLUME directly when not in the OSD Control menu*.
8 RESET/ECO	Resets the OSD back to factory settings in the OSD control menu. Switches among ECO MODE settings. Activates Auto Adjust function if helded for 3 seconds while the OSD menu is off (Analog input only)*.

* When Hot Key function is OFF, this function is disabled.

16.14 Maintenance Terminal - Dell Latitude E5570 Laptop

The Maintenance Terminal is a fixed laptop provided for Thales maintenance staff, enabling them to undertake diagnostics, software upgrades, software and data updates. This maintenance terminal also provides system status view for maintenance staff.

END

Equipment Identification

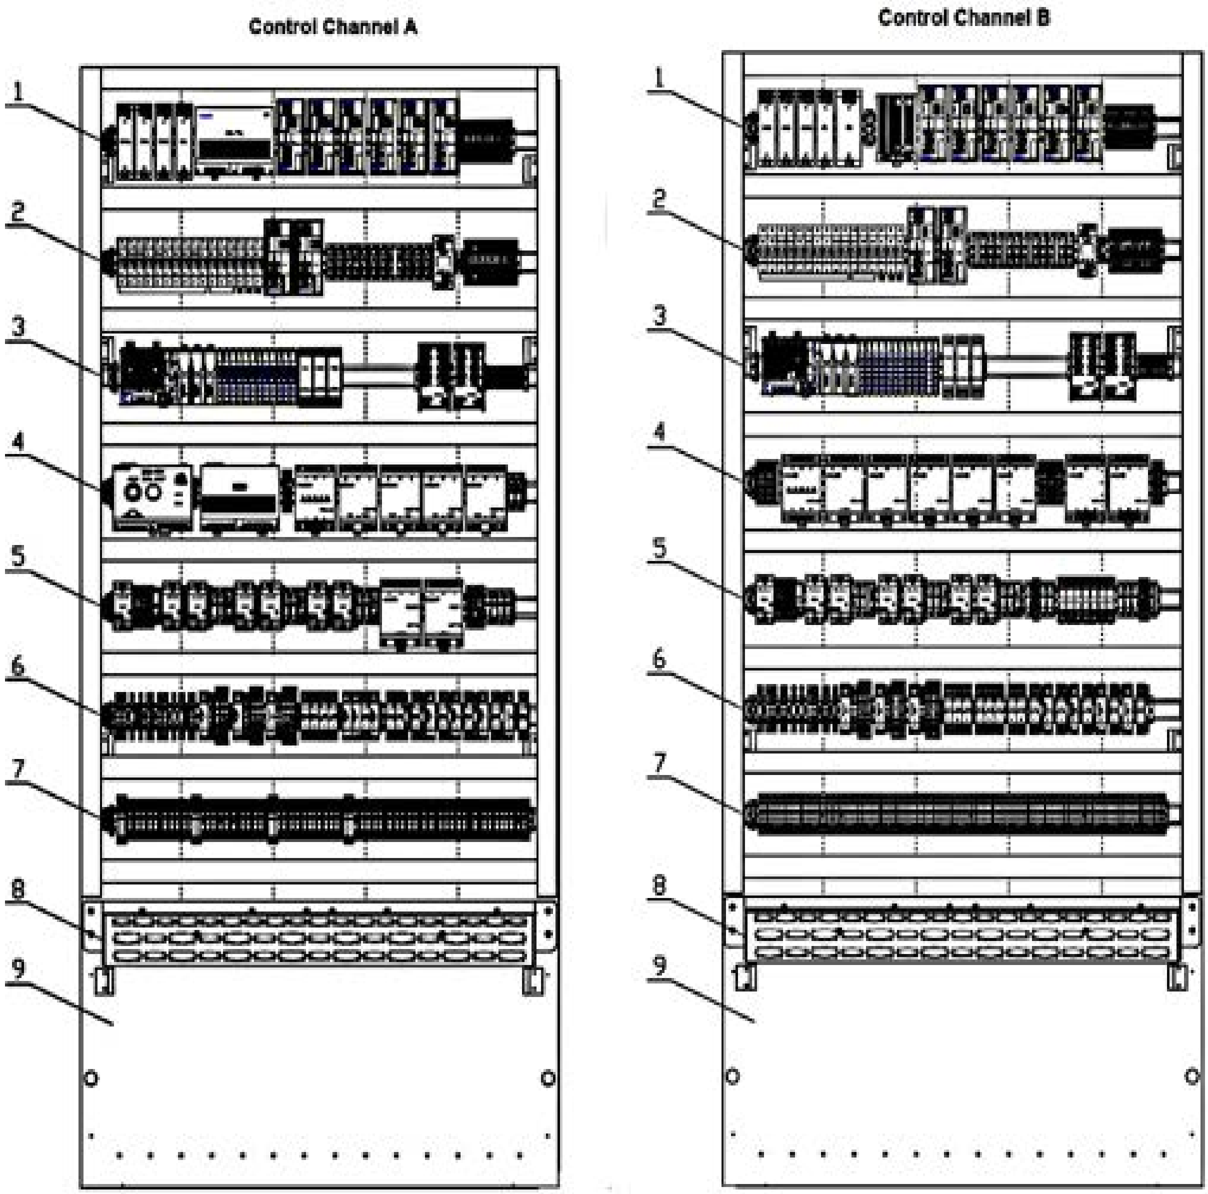
Section Index

1. Definitions & Abbreviations

EBI Gate 2000 (SPA-5/GBR)	Brand name for the family of SPA-5 level crossing systems
LX	Level Crossing System. Set of devices that warn road users about approaching trains.
PLC	Programmable Logic Controller
CPU	Central Processing Unit – main part of the PLC
PE	Protective Earth
+UA, +UB	Isolated power supply voltages for Control Channels A and B
RCD	Residual Current Device
ERP-9	Remote Control Device
DnC	Diagnostic and Control
CF	Compact Flash - Memory card installed in the CPU socket
POD	Primary Obstacle Detector
COD	Complementary Obstacle Detector
DVR	Digital Video Recorder
BPM	Barrier Protection Modules
ERR-8	Set of Power Supply and Control Racks ERR-8 Release 01 for *EBI* Gate 2000 (SPA-5/GBR)

2. Control Rack – Layout & Equipment Descriptions

2.1 Control Rack Layout



Control Channel A	
Number	**Terminal Strip ID**
1	LAA
2	LAB
3	LAC
4	LAD
5	LAE
6	LAF
7	Plug coupler sub-assembly
8	
9	

Control Channel B	
Number	**Terminal Strip ID**
1	LBA
2	LBB
3	LBC
4	LBD
5	LBE
6	LBF
7	Plug coupler sub-assembly
8	
9	

2.2 Control Rack – Manual Control Module EMH-261

EMH-261 module is equipped with:

- Button (with backlight) used during system start up procedure,
- Two LED indication lamps informing about correct operation of the data logger function.

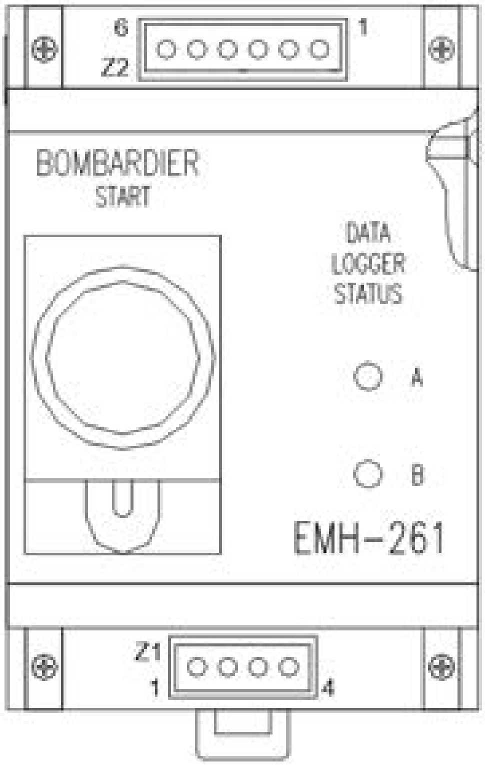


Fig. 1. EMH-261 front view

2.3 Control Rack – Manual Control Module EMH-264

EMH-264 module is equipped with:

- Button that enables the function of red road light failure reset,
- Button that enables the function of obstacle detection alarm reset,
- Switch that enables control over COD shutters,
- Switch that enables control over BOD outputs.

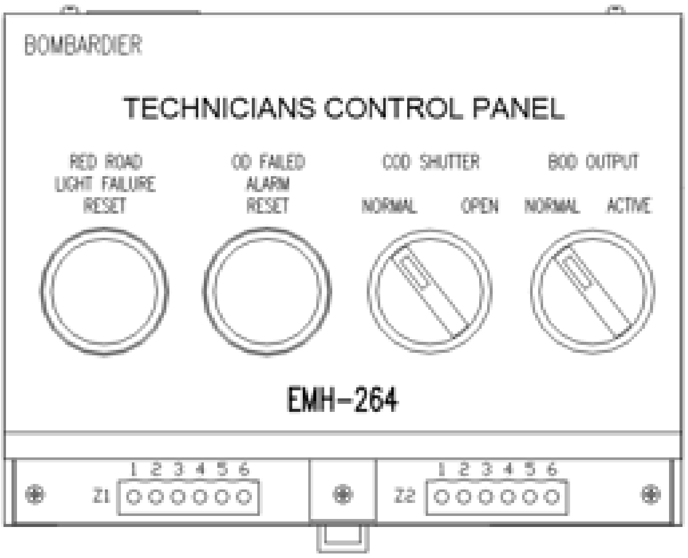

Fig. 2. EMH-264 front view

2.4 Control Rack – Digital input modules

There is a set of digital input modules connected to each CPU within each PLC.

The working status of the each module is reported via lit “r” LED placed on the front panel.

The “e” LED should remain turned off. The status of each pin (DI1, DI2, etc.) is indicated by green LEDs with indicating numbers.

When an input is in active state a corresponding LED is lit.

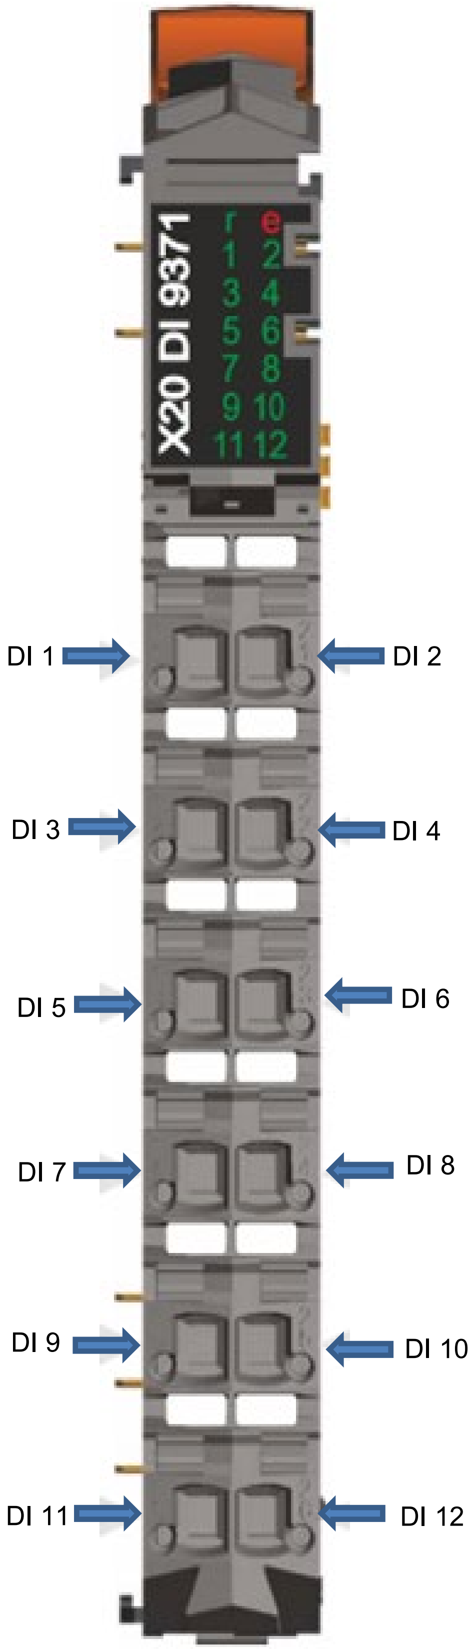

Fig. 3. Input module X20DI9371 (12 inputs)

2.5 Control Rack – Digital output modules

There is a set of digital output modules connected to each CPU within each PLC.

The working status of the each module is reported via lit “r” LED placed on the front panel.

The “e” LED should remain turned off. The status of each pin (DO1, DO2, etc.) is indicated by orange LEDs with indicating numbers.

When an output is in active state a corresponding LED is lit.

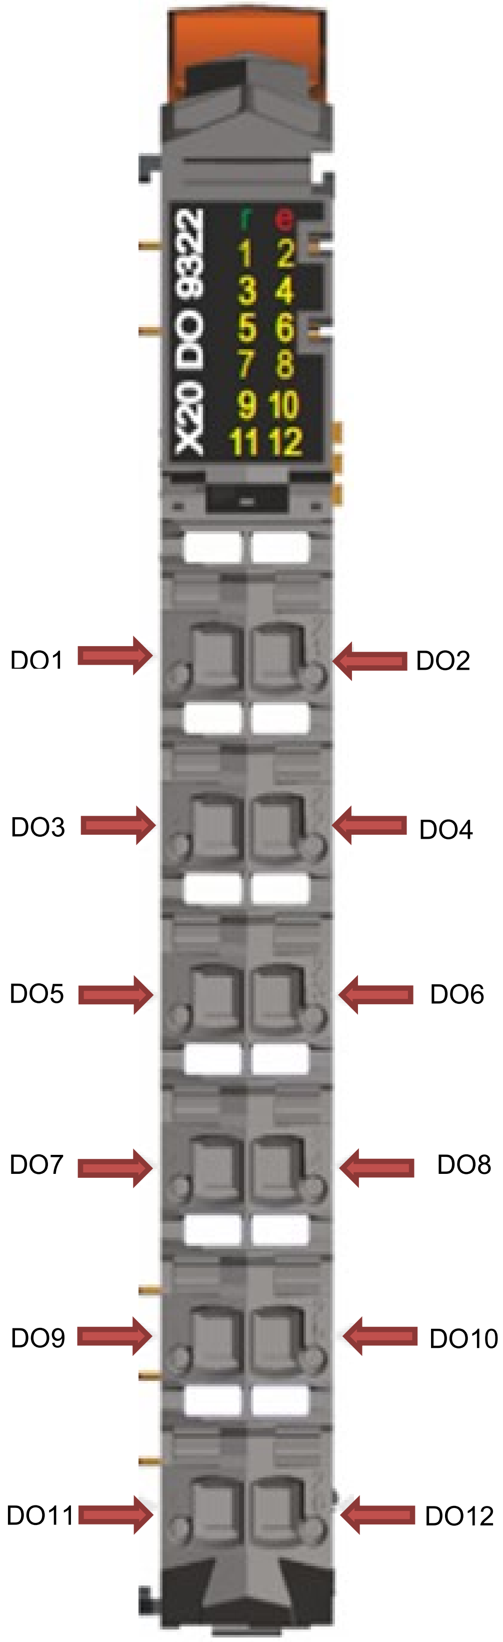

Fig. 4. Output module X20DO9322 (12 outputs)

2.6 Control Rack – List of input and output signals

The inputs and outputs are numbered according to following rules:

- groups represent PLC input or output modules that are marked from left to the right using capital letters A, B, C, ... ,
- The version of the group configuration is marked with number 1, 2, ...

LED No.	Terminal	Description	Signal in Control Channel A	Signal in Control Channel B
1	11	Gen1 Waveform	inGen1 A	inGen1 B
2	21	Gen1Start LX	inGenStart A	inGenStart B
3	12	Hut door	inHutDoor A	inHutDoor B

Table 10 - Output group J1/GBR (DO 12out module)

2.7 Control Rack – Power Supply Module EMF-8

Power Supply Modules EMF-8 are controlling chambers of road signals. The external elements of EMF-8 are presented below:

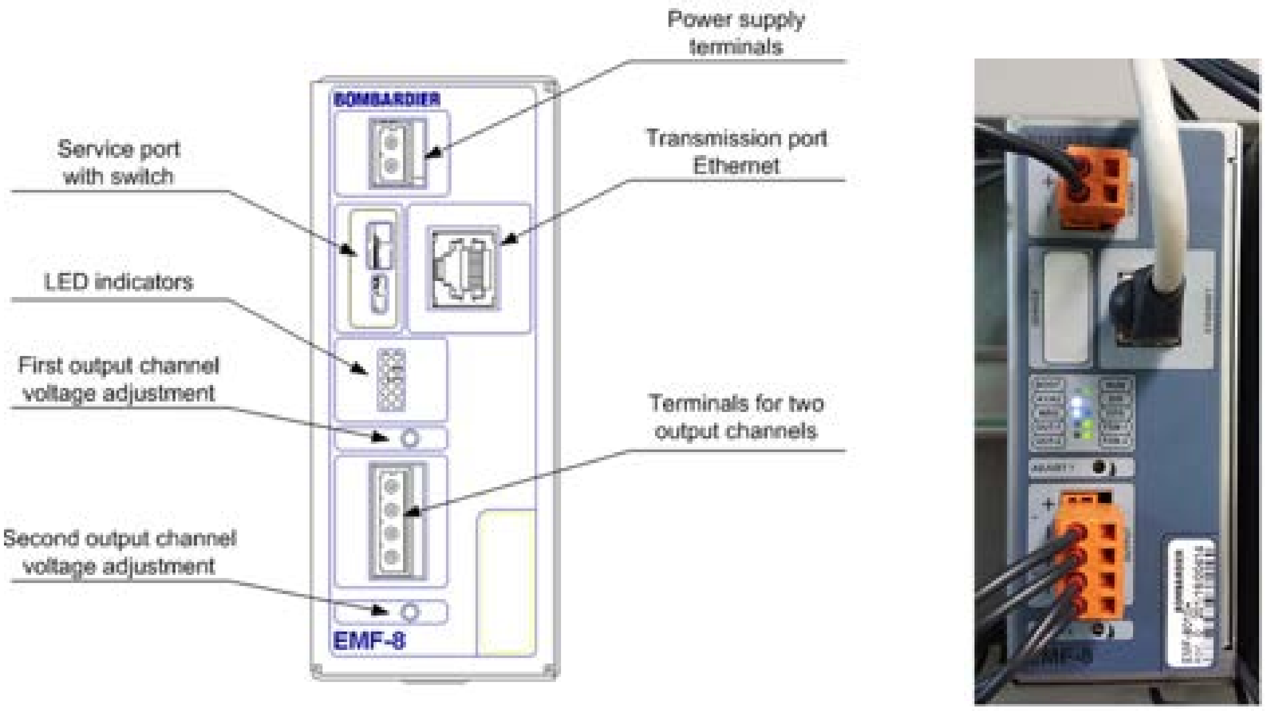

Fig. 5. Power Supply Module EMF-8

Fig. 6 - Power Supply Module EMF-8, Sound Generator EDG-5 – LED indicators

The meanings of LED indicators (front panel description in brackets):

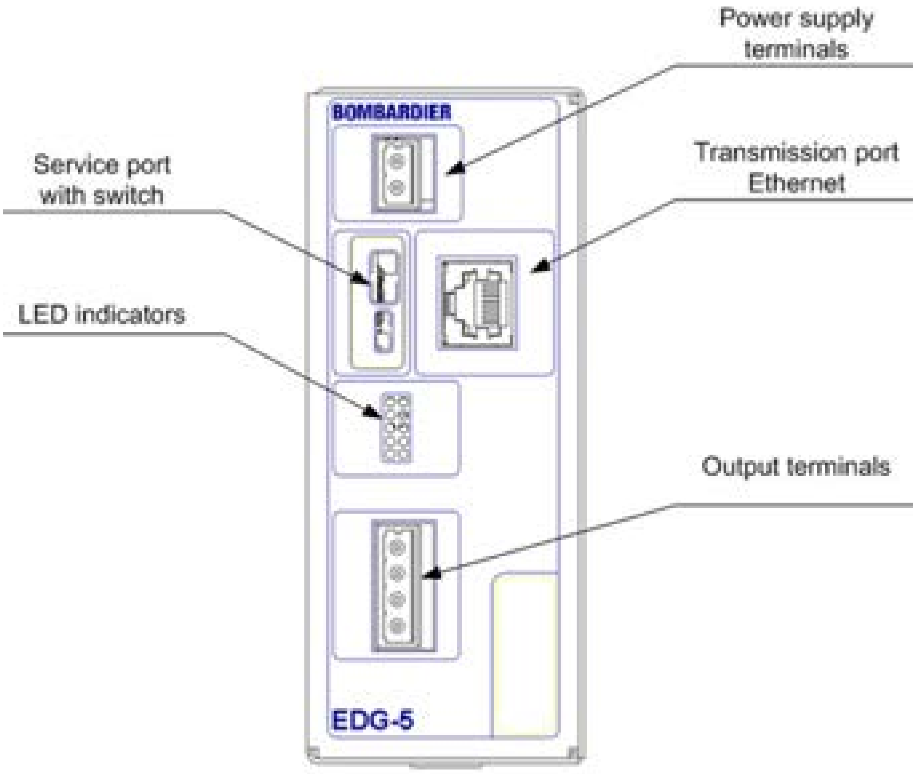
- TransmissionRx (MSG) - LED blinks for about 100ms after receiving message,
- ActiveModes (A1/A2):
  - LED continuous on – Active,
  - LED 2Hz flash – Active Without Transmission,
  - LED off – in case of all other states.
- OutputSignal (OUT1, OUT2) - requested state of output signals,
- DiagStart (D/S):
  - LED off – no Diag or Start state,
  - LED on – Start state,
  - LED 2Hz flashing – Diag state.
- Feedback (FDB-1, FDB-2) – read back state of output signal:
  - LED on – output signal is active,
  - LED off – output signal is inactive,
  - LED 10Hz flashing – output signal state is incorrect.
- Config (CFG):
  - LED off – configuration OK,
  - LED 2Hz flashing – no configuration data,
  - LED 1Hz flashing – invalid configuration data.
- Run (RUN) – blinks for about 10ms when device works properly with about 2Hz frequency, continuous on or off when device stops.

Fig. 7. Power Supply Module EMF-8, Sound Generator EDG-5 – Service port

- Service port of EMF-8 shall be sealed with a special sticker.

2.8 Control Rack – Sound Generator EDG-5

- Sound Generators EDG-5 are controlling acoustic warning signals. The external elements of this module are presented below:



- The meaning of LED indicators is the same as for EMF-8.

- Service port must be sealed with a special sticker.

2.9 Control Rack – Signal Amplifier EDZ-35

Signal Amplifier EDZ-35 consists of five electronic keys acting as buffers for PLC outputs.

Each output circuit (K1, K2, K3, K4, K5) is equipped with voltage and current indication circuit with two LED lamps.

In each pair the green LED represents the output voltage detection and the red LED represents current detection.

Fig. 9. Signal Amplifier EDZ-35

2.10 Control Rack – Electronic Key EDZ-5

Electronic Key EDZ-5 is a simple electronic key. It is equipped with red LED lamp which is lit when the module is activated.

Fig. 10. Electronic Key EDZ-5

2.11 Control Rack and Power Supply Rack – Earth Leakage Detector

Power supply channels A and B are insulated with each other and with the equipotential bar PE.

The Earth Leakage Detectors are applied to check the resistance between PE, UA and UB. There is also an “Earth Leakage Detector” in power supply channel C.

The “Earth Leakage Detector” is equipped with:

- LCD display which presents actual value of insulation resistance,
- ON LED lamp which is lit when the module is powered,
- Two AL1, AL2 LED lamps informing about two levels of insulation degradation.

Fig. 11. Earth Leakage Detector

2.12 Control Rack – Current Transducer

Current Transducer is applied in control circuit of barrier machines to allow high current measurements for analogy input cards of PLC A and B.

It is equipped with LED indicator informing that the module is powered (PWR) and that an error in module operation was detected (ERR).

Current Transducer has two plugs.

Fig. 12. Current Transducer - WAGO current measurement unit

2.13 Control Rack – ETHERNET Switch

The ETHERNET communication is held via ETHERNET switches. These modules are equipped with LED lamps:

- Pwr – the module is powered,
- L/A is lit up green – link is active,
- L/A is flashing green – link is active and data is transferred.

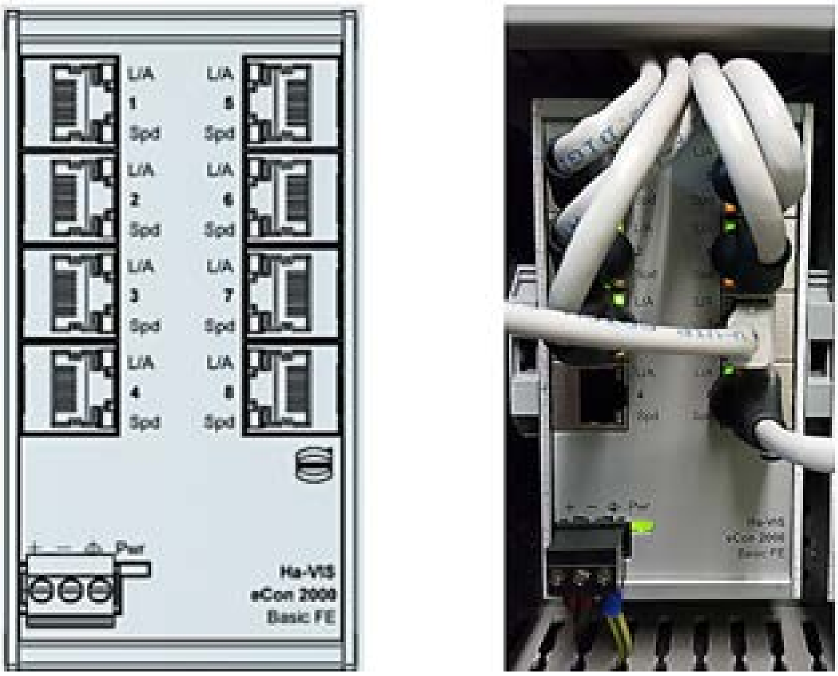


Fig. 13. ETHERNET Switch

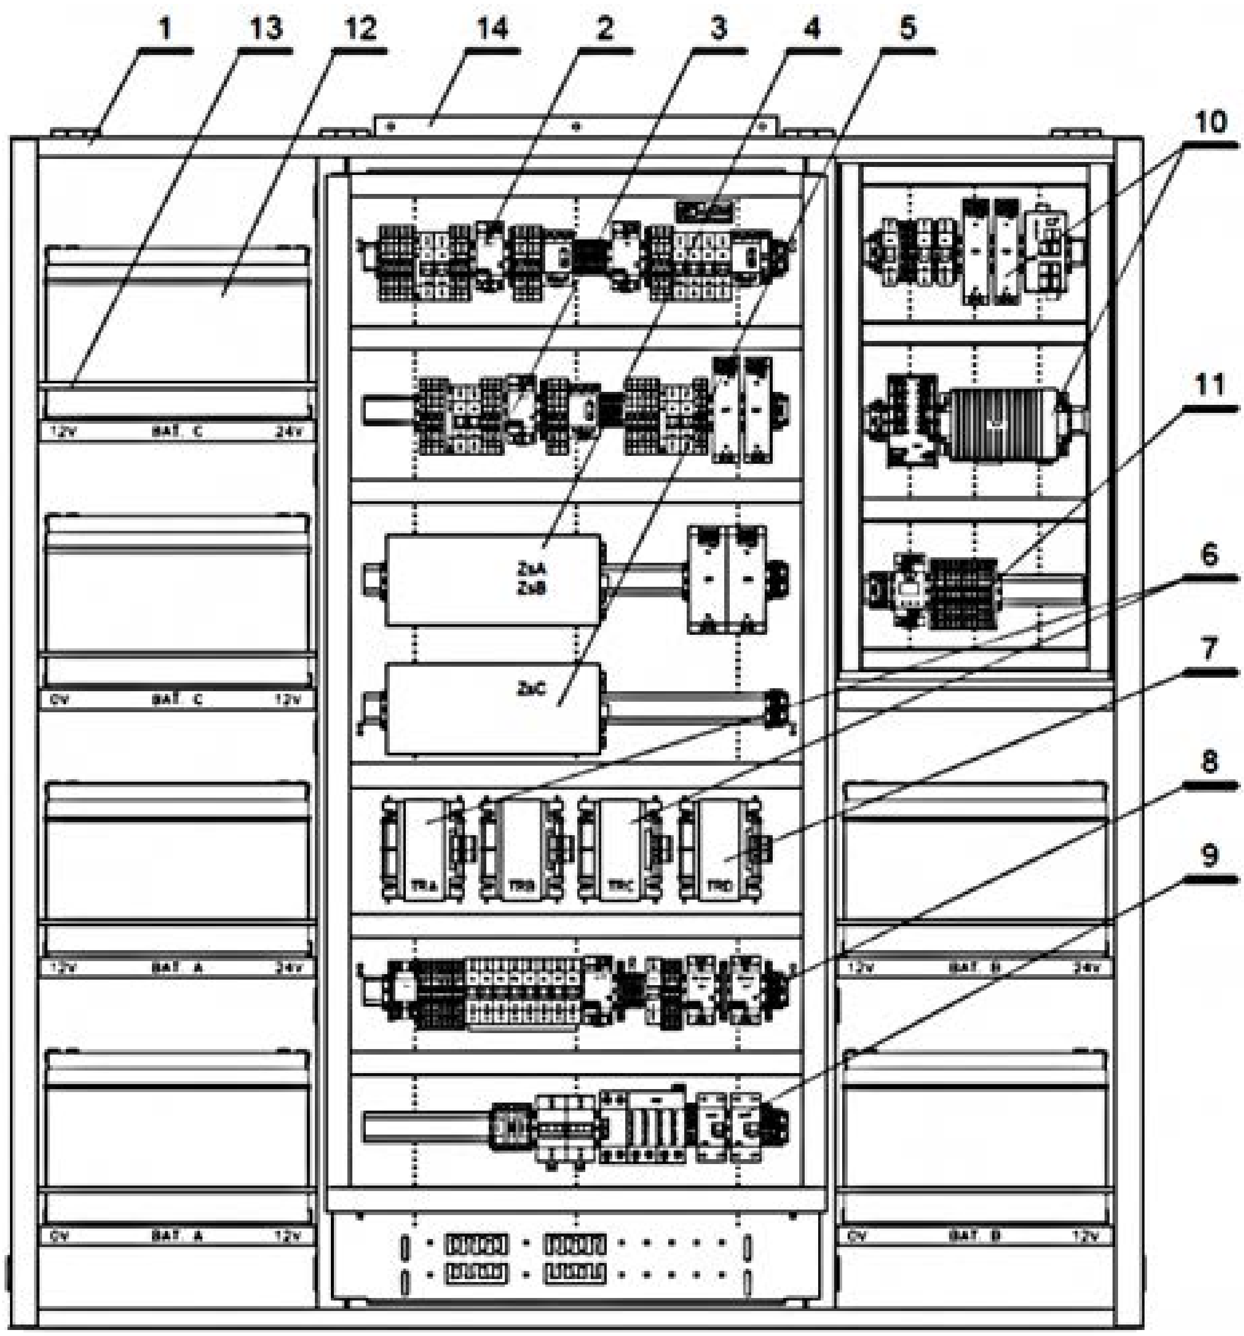
3. Power Supply Equipment and Fuses

3.1 Power Supply Rack – General View



Number	Description
1	Chassis
2	ZZA Terminal Strip
3	ZZB Terminal Strip
4	ZZC Terminal Strip
5	ZZX Terminal Strip
6	Transformers TRA, TRB & TRC
7	Autotransformer TRD

Number	Description
8	ZZD Terminal Strip
9	ZZE Terminal Strip
10	LTZ Module
11	ZZE Terminal Strip in LTZ Module
12	Batteries 12v, 85 Ah
13	Battery Blocking Bars
14	Mounting Bracket

3.2 Power Supply and Control Racks – Before switching on checklist

Before switching on the ERR-8 below listed steps have to be performed:

- Check using AC voltmeter if the main power supply voltage is above 195V,
- Check using DC voltmeter if batteries voltage is above 26V,
- Perform visual inspection of all terminal strips,
- Check if all fuses are turned off in terminal strips LAB and LBB.

3.3 Power Supply and Control Racks – Switching on and off

To switch on the ERR-8 follow the instructions described in the manual, To switch off move downward levers of all fuses listed in 3.4

3.4 Power Supply and Control Racks – Manual restart procedure

It is enough to switch off only the fuses LA and LB on Control Racks to execute manual restart procedure.

3.5 Power Supply and Control Racks – Fuses

On both racks there is a set of fuses that check power supply for ERR-8 sub-circuits.

In order to turn on a fuse move the lever up to the end.

In order to turn off move the lever downward.

The list of all fuses with explanation of their function and position on the racks:

Power supply rack

TYTAN	Fused mains power switch
ISOLATION SWITCH	Safety mains power disconnector
FA	Mains power supply for power channel A
FB	Mains power supply for power channel B
FC	Mains power supply for power channel C
FD	Mains power supply for POD internal heater
TV	Mains power supply for DVR LCD
FL	Internal lighting
FF	Fan
FS	General purpose electric outlet, heater
P.P	Smoke detector
RCD1, RCD2	Residual Current Device
ZA	Power channel A: batteries load fuse
ZB	Power channel B: batteries load fuse
ZC	Power channel C: batteries load fuse
ZiA	Power channel A: battery charging fuse
ZiB	Power channel B: battery charging fuse

ZiC	Power channel C: battery charging fuse
BS	Power supply for COD shutter motors
BV	Power supply for DVR and BPM modules
BL	Power supply for CODs
BR	Power supply for POD

Control rack (channel A)

LA	Fuse of PLC in channel A
ODŁ.A	Fuse of EMB-1 module
RS14A	Fuse of red chambers in road signals 1, 2, 3, 4 (channel A)
RSYA	Fuse of amber chambers in road signals 1, 4, 5, 8
BMA	Fuse of group of barrier machines BM1 and BM3
RS58A	Fuse of red chambers in road signals 5, 6, 7, 8 (channel A)
D1	Fuse of audible signal DZ1
D5	Fuse of audible signal DZ5
BM1	Main fuse of barrier machine BM1
BM3	Main fuse of barrier machine BM3
B1	Fuse of electromagnetic brake in BM1
B3	Fuse of electromagnetic brake in BM3

Control rack (channel B)

LB	Fuse of PLC in channel B
INT	Fuse of output part of interlocking interface
RS14B	Fuse of red chambers in road signals 1, 2, 3, 4 (channel B)
RSYB	Fuse of amber chambers in road signals 2, 3, 6, 7
BMB	Fuse of group of barrier machines BM2 and BM4
RS58B	Fuse of red chambers in road signals 5, 6, 7, 8 (channel B)
D2	Fuse of audible signal DZ2
D6	Fuse of audible signal DZ6
BM2	Main fuse of barrier machine BM2
BM4	Main fuse of barrier machine BM4
B2	Fuse of electromagnetic brake in BM2
B4	Fuse of electromagnetic brake in BM4

3.6 Guidelines for Stabilized Power Supply DC/DC Converter MERAWEX

The output voltage of Stabilized Power Supply DC/DC Converter MERAWEX is adjusted during production process.

As the performance of lead-acid batteries depends on the charging voltage the user is not allowed to make any adjustments of their output voltage.

3.7 Guidelines for other DC/DC converters (Phoenix Contact)

The output voltage of other DC/DC converters (Phoenix Contact) is adjusted during its production and installation process. It is not allowed to make any adjustments of their output voltages.

3.8 Adjusting output voltage of Power Supply Module EMF-8

Power Supply Module EMF-8 consists of two independent DC/DC converters. It is used as a power supply for the road signals.

Adjustment of its output voltages can be done (when necessary) by means of two multi-turn potentiometers (shown below) with use suitable screwdriver.

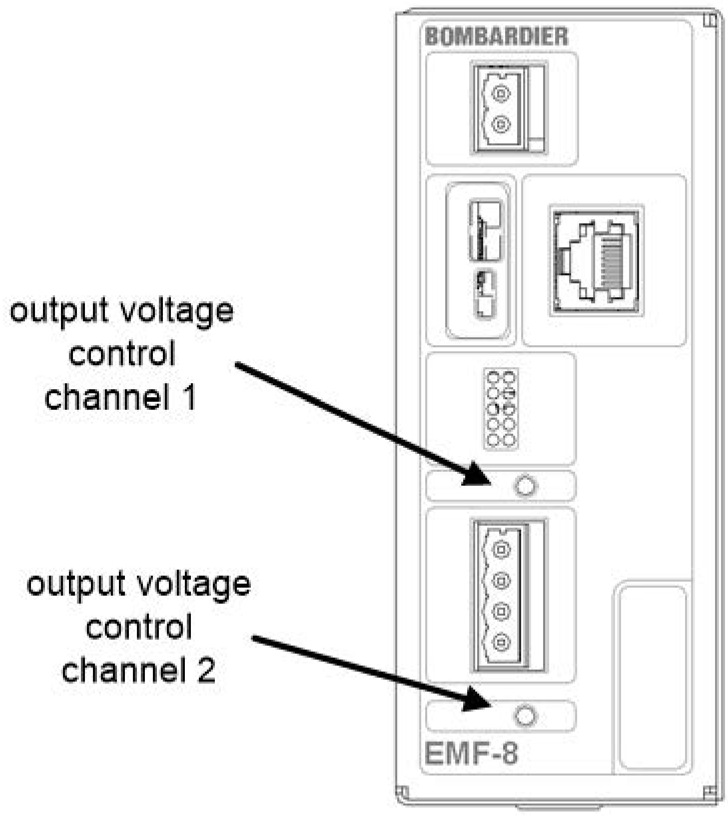


Fig. 14. Adjusting EMF-8 output voltage

END

This appendix covers the checking the status of various equipment at the interlocking, acronyms and system restart.

1. CALS Board (Internal)

1.1 Observe all the power supply LEDs of the CALs (CALS PAP i=1 to 3) are lit.

1.2 Check the PAP rack's circuit breaker is powered. The Start (green) button shall be engaged, the Stop (red) shall not be engaged.

1.3 If the circuit breaker is not powered, check incoming power. If this is within +-20% of 24 V, re-engage the circuit breaker.

1.4 If the circuit breaker trips again, replace the CALS board.

1.5 Using a meter, check the following voltages at the measurement points on the CALS board:

- 5V VME (+4.7 V to +5.5 V)
- =12V VME (+11.5 V to 12.5 V)
- -12V VME (-11.5 V to 12.5 V)
- 5V VL (+4.7 V to 5.5 V)
- 24 VREG (23 to 25V)

If these voltages are not measured, replace the CALS board.

2. CME+ Board

2.1 Observe the LEDs of the CME:

	VA	VA
(Unlit) E ⊗	(Flashing) ⊗ ⊗ (Steady)	(Flashing) ⊗ ⊗ (Steady)
	Rx	Tx
(Unlit) E ⊗	(Flashing) ⊗ ⊗ (Steady)	(Flashing) ⊗ ⊗ (Steady)
	VA	VA

If these indications are not correct, replace the CME+ board.

3. CIER Board

3.1 Observe the CIER board is displayed in red on the Technicians Terminal.

3.2 Observe on the front face of the CIER board that the LEDs of Ethernet ports 1 and 2 are not flashing. Also, and/or the two LEDS of the Console port are steady green or off.

If these indications are not correct, replace the CIER2 board.

4. CAP Board

4.1 Observe LEDS of the CAP board are in the following state:

(Flashing) BFL ⊗
(Flashing) CPU ⊗

If the CPU LED is lit, replace the CAP dongle (BCH).

If the LEDs are in the expected state, replace the CAP board.

5. CVO Board

5.1 Observe LEDS of the CVO board are in the following state:

lit)	W	⊗	⊗	H	(unlit)
(pulsating)	M	⊗	⊗	E	(unlit)
(flashing)	1	⊗	⊗	2	(unlit)

If these indications are not correct, replace the CIER2 board.

6. CIER Ethernet Cables

6.1 Disconnect the Ethernet cables between the CIER board and the Ethernet switch.

6.2 Using another Ethernet cable, connect between the CIER board and the Ethernet switch and check for the following states on the Technicians Terminals:

a) If the connection stays green, keep the new Ethernet cable.

b) If the connection remains faulty, reconnect the existing Ethernet cable.

7. Acronyms

Acronym	French Meaning	English Meaning
AG	**AG**uile	Point
BCH	**B**ou**CH**on	Dongle
CALM	**C**arte **AL**imentation d'une architecture bi-**M**TOR	Power Supply Board for MTOR architecture
CALS	**C**arte **AL**imentation **S**ol	Power Supply Board
CAP	**C**arte d'**A**p**p**lication	Processing Unit Board
CIER	**C**arte **I**nterface **E**thernet **R**éseau	Ethernet Network Interface Board
CG	**C**hien de **G**arde	Watchdog
CME	**C**arte **M**émoire d'**E**change	Shared Memory Board
CRCD	**C**arte à **R**elais à **C**ommande **D**iversifiée	Duplicated Output Relay Board
CSD	**C**alculateur de **S**écurité **D**isponible	Module containing CAP, CVO & CME boards and CAP & CVO dongles
CVO	**C**arte **VO**teur	Voting Board
HES	**H**ybride d'**E**ntrée de **S**écuité	Hybrid Safety Inputs
MTOR	**M**odule **T**out **O**u **R**ien	Digital Module
PAP	**P**anier d'**AP**plication	Application Rack
PES	**P**anier d'**E**ntrées / **S**orties	Inputs / Outputs Rack
PVF	**P**anier d'**V**entilation **F**orcée	Forced Ventilation Rack
SEI	**S**ystème d'**E**nclenchement **I**nformatisé	Interlocking System
SSKC	**S**ous-**S**ystème (**K**) **C**ontrôleur commande	I/O Module command control sub-system
SX	**S**ignau**x**	Signal
TTD	**T**erminal **T**echnique **D**eporté	Remote Technicians Terminal
UT	**U**nité de **T**raitement	Processing Unit

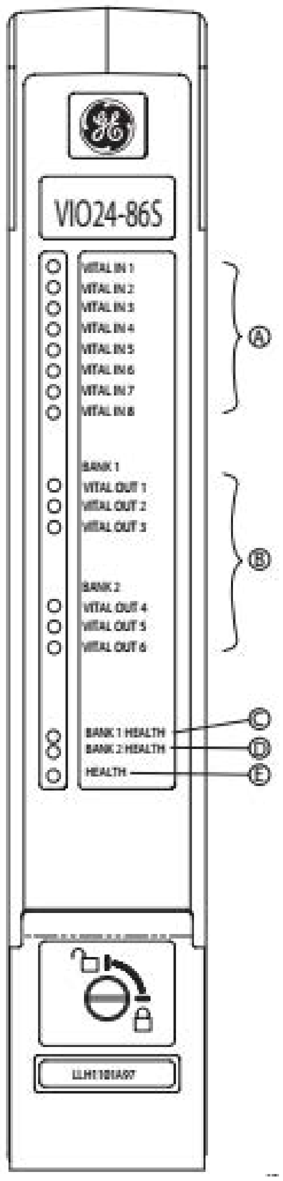
8. Interlocking Restart

When restarting the interlocking, all interlocking controls such as route bars, shall be reapplied using the TT.

END

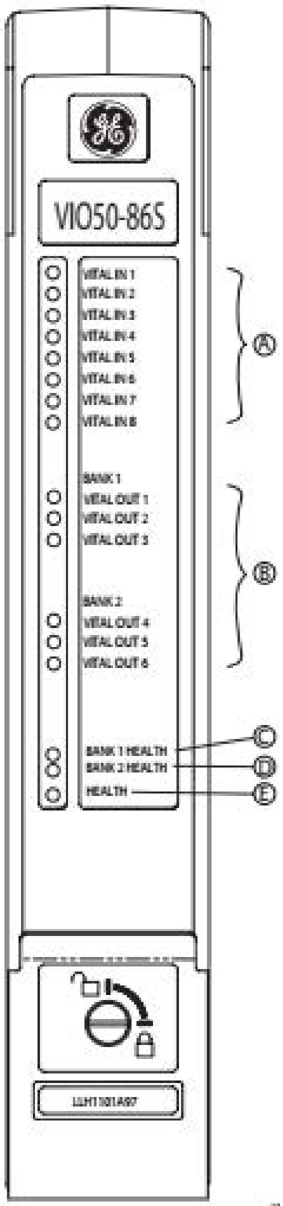
Status and Description of LED Indications.

1. VIO24-86S



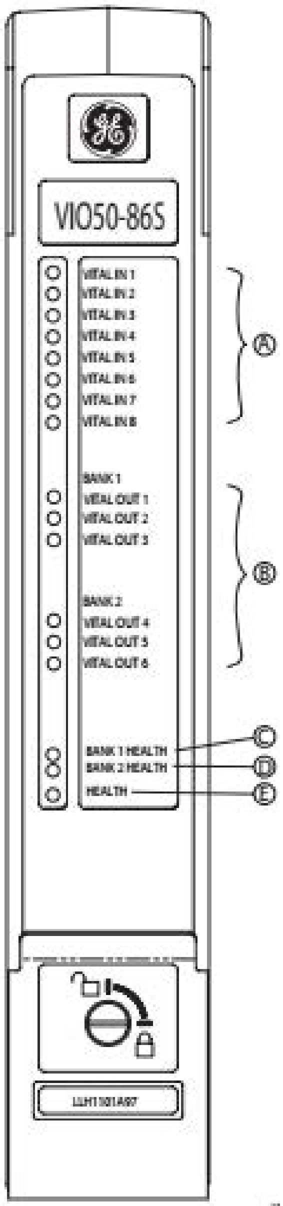
VIO24-86S		
LED	**Status**	**Description**
A. VITAL IN 1-8	On	Input is energised (When input rises above 16.0 ± 0.5VDC). Will accept voltages up to 64 VDC.
A. VITAL IN 1-8	Off	Not Energised (When input falls below6.0 ± 0.5VDC)
B. VITAL OUT 1-3	On	Output is energised
B. VITAL OUT 1-3	Off	Not Energised
B. VITAL OUT 4-6	On	Output is energised
B. VITAL OUT 4-6	Off	Not Energised
C. BANK 1 HEALTH	On	Bank 1 vital outputs 1-3 are functioning properly.
C. BANK 1 HEALTH	Off	1 or more of Vital Outputs 1-3 has failed. If 1 Vital Output fails the other 2 Vital Outputs on the same Bank are shutdown.
D. BANK 2 HEALTH	On	Bank 2 vital outputs 4-6 are functioning properly.
D. BANK 2 HEALTH	Off	1 or more of Vital Outputs 4-6 has failed. If 1 Vital Output fails the other 2 Vital Outputs on the same Bank are shutdown.
E. HEALTH	On	Module able to function properly.
E. HEALTH	Off	Module is in Safe State Retention State (check system log & Alarms).

2. VIO50-86S



VIO50-86S		
LED	**Status**	**Description**
A. VITAL IN 1-8	On	Input is energised (When input rises above 39.0 ± 0.5VDC). Will accept voltages up to 64 VDC
A. VITAL IN 1-8	Off	Not Energised (When input falls below12.5 ± 0.5VDC)
B. VITAL OUT 1-3	On	Output is energised
B. VITAL OUT 1-3	Off	Not Energised
B. VITAL OUT 4-6	On	Output is energised
B. VITAL OUT 4-6	Off	Not Energised
C. BANK 1 HEALTH	On	Bank 1 vital outputs 1-3 are functioning properly.
C. BANK 1 HEALTH	Off	1 or more of Vital Outputs 1-3 has failed. If 1 Vital Output fails the other 2 Vital Outputs on the same Bank are shutdown.
D. BANK 2 HEALTH	On	Bank 2 vital outputs 4-6 are functioning properly.
D. BANK 2 HEALTH	Off	1 or more of Vital Outputs 4-6 has failed. If 1 Vital Output fails the other 2 Vital Outputs on the same Bank are shutdown.
E. HEALTH	On	Module able to function properly.
E. HEALTH	Off	Module is in Safe State Retention State (check system log & Alarms).

3. VLD-R8AC



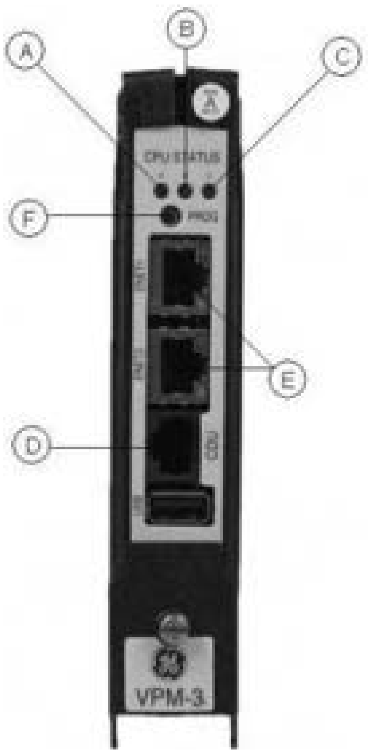
VLD-R8AC		
LED	**Status**	**Description**
A. LAMP 1-8	On	Lamp Output LED is lit when corresponding Lamp Output is energised.
A. LAMP 1-8	Off	Lamp Output LED is not lit when corresponding Lamp Output is not energised. See Note 1. All Lamps out, See Note 2.
B. VSSR	On	Vital Signal Stop Relay is energised.
B. VSSR	Off	VSSR is disabled. See Note 1. See Note 2. See Note 3.
C. HEALTH	On	Module Health LED is lit when VSSR is energised and all internal self-tests pass.
C. HEALTH	Off	Input power is <85VAC RMS or 110VAC lost for more than 0.5s or one or more health check failed, VSSR output disabled. VLD is in Safe State. (It will be 30s before the module attempts to recover).

Note 1: The VLD-R8AC contains feedback circuitry to allow the VPM to monitor and report on the integrity of the lamp output circuitry. The response to a detected fault on defined outputs (off when should be on, on when should be off, etc.) is a de-energising of all the Lamp Outputs and a disabling of the Vital Signal Stop Relay (VSSR) output. After a lamp module has been shut down, the VPM disables the eight Lamp Outputs and the VSSR output for a minimum of 30 seconds. After 30 seconds have passed, the VSSR output is enabled and the VPM performs a health check. If the lamp module passes the health checks, the VLD-R8AC resumes normal operation. Otherwise, if the lamp module fails one or more health checks, the VSSR output is disabled and the VPM waits another 30 seconds before retrying.

Note 2: If the VLD-R8AC internal monitoring circuit senses an unsafe fault all outputs on the module are de-energised and the VSSR output is de-energised. Outputs that are red-retained are immediately energised over a back contact of the VSSR.

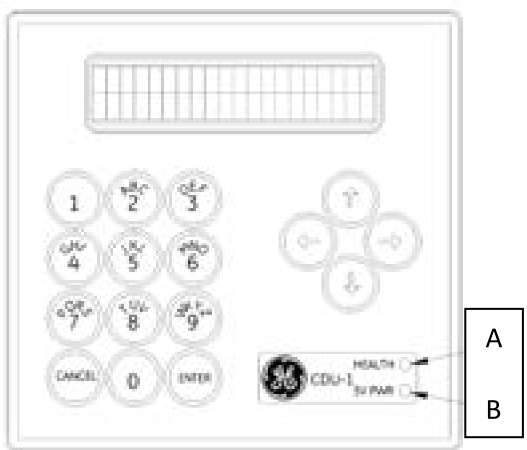
Note 3: If the VSSR de-energises due to a failure in the VLD-R8AC module, the module cannot be re-initialised without manual intervention. If the VSSR de-energises due to power failure, the module and VSSR will re-initialise automatically when power is restored.

4. VPM-3



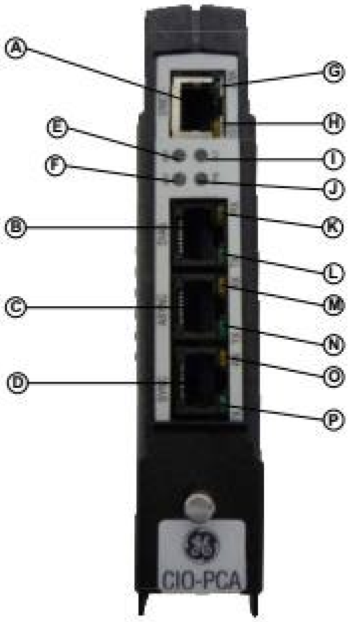
VPM-3		
LED	**Status**	**Description**
A, B or C	Off	CPU is not functioning.
A, B or C	Steady On	The CPU is initialising (only valid status during startup). If one or more continuously illuminated during normal operation, the CPU is not functioning.
A, B or C	Flashing	CPU is Active and functioning normally
All three CPU LEDs	Flashing amber/ red pattern	Update mode (the mode used to update VPM-3 executive software or application programs).
E. Green LED Ethernet connection	Steady/ Flashing	Connected/active
E. Amber LED Ethernet connection speed	On	100Mbs
E. Amber LED Ethernet connection speed	Off	10Mbs
F. Prog Button		1. If depressed during a power cycle, causes the VPM-3 to enter update mode. 2. Used to confirm Local Presence when requested.

5. CDU-1



CDU-1		
LED	**Status**	**Description**
A. HEALTH	On	System CPUs are operating normally
A. HEALTH	Off	A CPU has halted/or not operating and also during system resets.
B. 5V PWR	On	Output of Central Power Supply is within acceptable parameters.
B. 5V PWR	Off	No power

6. **CIO-PCA**



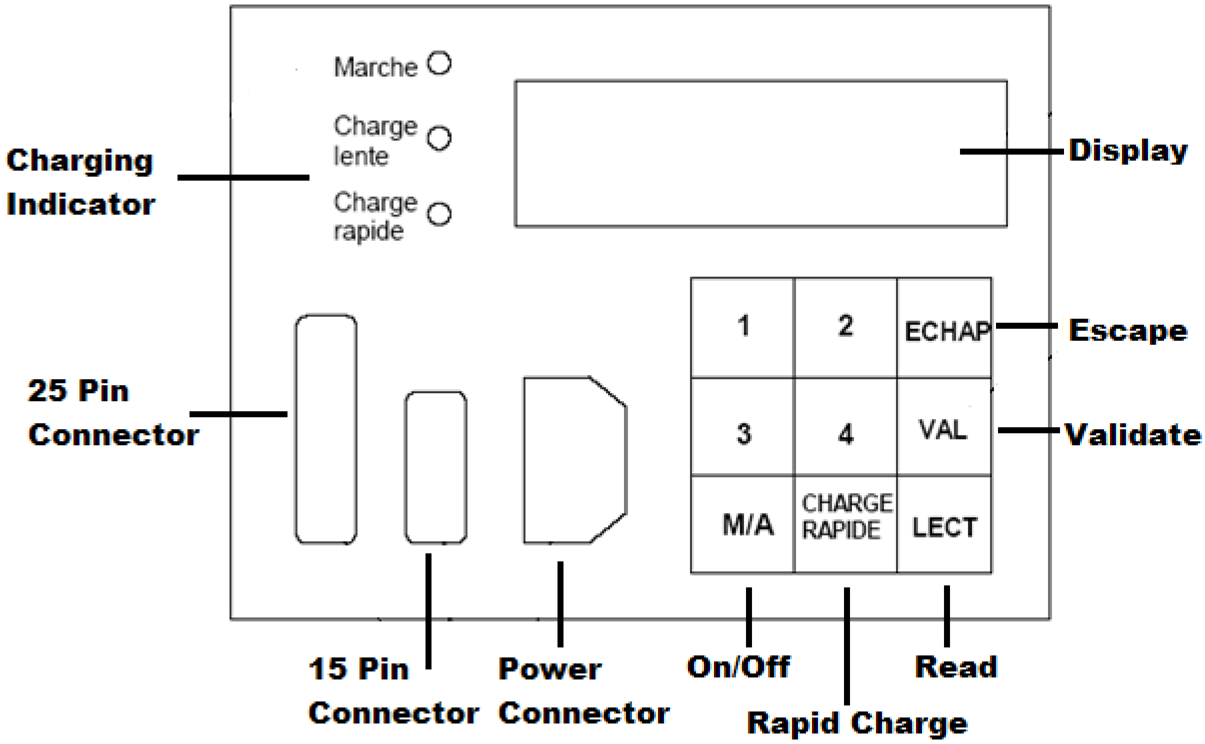
VPM-3		
LED	**Status**	**Description**
E. BKP	On	Receiving data from ElectroLogIXS backplane
F. ASY	On	A valid frame (good CRC) has been received from ASYNC (radio control) port.
G. LINK	On	Ethernet connected to ElectroLogIXS and active
G. LINK	Flashing	Activity on the link
H. 100 (Amber)	On	Ethernet data rate. Connection at 100M
H. 100 (Amber)	Flashing	Data collisions detected
I. HLT	Flashing	CIO-PCA Health. LED flashes approx. once per second when module functioning properly
J. SYN	On	A valid frame (good CRC) has been received from SYNC (radio control) port.
K. RX (Amber)	On	Receive data present on DIAG port to ElectroLogIXS
M. RX (Amber)	On	Receive data present on ASYNC port to ElectroLogIXS
O. RX (Amber)	On	Receive data present on SYNC port to ElectroLogIXS
L. TX (Green)	On	Transmit data present on DIAG port to ElectroLogIXS
N. TX (Green)	On	Transmit data present on ASYNC port to ElectroLogIXS
P. TX (Green)	On	Transmit data present on SYNC port to ElectroLogIXS

END

1. Equipment Description

SNCF Catalogue number for the tester and all the associated cables is: 7.954.5494, Supplier: ALSTOM. This will become stand PADS number after trial Certification.

It is a portable tool with and is designed to be laid flat on the balise. The upper face features: a display, three light indicators, three connectors and a nine touch keypad.



*****IMPORTANT NOTE*****

The Battery Life for the tester is an estimated 3 hours. The Tester is to remain on charge when not in use.

There are two charging rates available;

- 'Charge Lente' Slow Charge – 30 Hours
- 'Charge Rapid' Fast Charge – 14 Hours

If 'Charge Rapid' is used, the tool will automatically switch back to Charge Lente after the charge cycle has completed and can be powered by at this rate continuously.

When the tool has less than 10 mins remaining, a 'BAT' message will display on the right hand side of the display.

2. Main functions

The test tool is capable of all measurements necessary for the installation and maintenance of the Balises. It is used for testing both KVB SN Balises and encoders, and can carry out the following functions:

- Test “serial” Balises and display the messages.
- Read “serial” message on an encoder output.
- Read “serial” message on maintenance connector of the encoder SBI card.
- Read messages at the end of a Balise tail cable.
- Read maintenance messages produced by encoder through the UCS maintenance card.

3. Accessories

The Test tool should have the following cable connectors as part of the kit:

- Mains cable and supply power connector.
- 25-pin cable to SBI Card Output
- 25-pin cable to UCS Card
- 25-pin cable to Balise tail cable
- 15-pin cable to SBI Maintenance Output

Figure1 - Cable connector identification

4. Test tool software

The Maintenance Tool software reference is V 2 0 0.

This software version can be identified by switching on, press the ‘M/A’ (on/off) and the ‘1’ key simultaneously.

The version number will be displayed for 6 seconds.

5. Using the Test Tool

5.1 Starting & selecting a function

To turn on the tester, press ‘M/A’ key on the keyboard.

To switch the tester off, press the ‘M/A’ key again.

The tool automatically selects the function to be performed by recognizing the connection that has been made.

If two connections are made simultaneously, the message “double connexion en entrée interdite” (double connection in inputs are forbidden) is displayed.

If there is no cable, the “test balise” function is automatically selected.

6. Reading either encoder or extension encoder maintenance messages

6.1 With the tester connected to the UCS maintenance card, after turning on, the following is message is displayed;

1	.	A	F	F	I	C	H	E		C	O	N	F	I	G				
2	.	L	E	C	T	U	R	E		I	N	C	I	D	E	N	T	S	
3	.	E	T	A	T		D	E	S		E	N	T	R	E	E	S		
4	.	E	F	F	A	C	E	M	E	N	T		M	E	M	O	I	R	E

6.2 Choose the required function by pressing key ‘1’, ‘2’, ‘3’ or ‘4’.

Key ‘1’ allows the encoder configuration. See Section 7

Key ‘2’ allows the reading of the encoder failure memory. See Section 8

Key ‘3’ makes it possible to read continuously the encoder input states. See Section 9

Key ‘4’ allows the erasing of the encoder failure memory. See Section 10.

A standby message is displayed as soon as any of these four key has been pressed.

VEUILLEZ PATIENTER

(Please Wait)

7. Encoder Configuration

Key '1' makes it possible to display the input card types, the balise driven by every output and the number of programmed messages for every output.

CE1:ELI IS1:A 023MES
CE2:ECI IS2:A 008MES
CE3:ECI IS3:A 012MES
CE4:--- IS4:NON UTIL

This display describes the following configuration:

- 1st input card: ELI (not used in UK)
- 2nd input card: ECI
- 3rd input card: ECI
- 4th input card non installed
- Output 1: balise of type A with 23 programmed messages (including one anomaly message)
- Output 2: balise of type A with 8 programmed messages (including one anomaly message)
- Output 3: balise of type A with 12 programmed messages (including one anomaly message)
- Output 4: free

7.1 As soon as the configuration is displayed the operator can access the encoder software version number by pressing key "1".

CODEUR / EXTENSION
VERSION LOGICIELLE
XXX

(Encoder/extension – Software version)

7.2 Pushing on key 'ECHAP' (escape) returns the user to the main menu.

8. Reading the Fault Memory

8.1 From the main menu shown in section 6, press key ‘2’ to read the fault memory.

Pressing the ‘VAL’ key returns the user to the previous failure.

8.2 Record any failure and investigate where practicable.

8.3 Escalate any failure to SM’s.

Transferring data from the UCS card failure memory into the tool can last a few seconds. During this period of time the standby message is displayed. If no failure is recorded the following message is displayed:

AUCUN INCIDENT
ENREGISTRE

(No failure recorded)

If there are any failures the last failure is displayed:

INCIDENT 8/8
LB XXXXX LA XXXXX
ADR XXXXXX
0001J 09H 29MN 12S

The first line shows the failure number and all the failures recorded (in this example the 8th failure out of 8 recorded).

The second line makes clear the kind of encoder software mistake either for LB (firmware) or LA (application).

The tables of the main failure codes and their meaning can be found below.

The third line shows the software address (if the information is available) where the failure happened.

The fourth line specifies the time spent between the moment the failure has taken place and its reading by the tool in days, hours, minutes and seconds (in this example the 8th failure took place 1 day, 9 hours, 29 minutes and 12 seconds before being read by the tool).

Note: An encoder power supply failure disturbs the earlier failures dating. If the tool detects the power supply failure (by inconsistency between the failure order in the memory and the dating values); it will not display any time value for the earlier failures. If it does not detect it the time values will be distorted.

List of Error Codes

Applicative software errors

Error codes #	Description
100	No error
101	Non detected breakdown
107	Lack of BCC
108	New BCC
109	BCC reading anomaly
110	Incorrect BCC checking sum
111	Incorrect BCC signature
112	Incorrect n°1 input card signature
113	Incorrect n°2 input card signature
114	Incorrect n°3 input card signature
115	Incorrect n°3 input card signature
116	Incorrect input card signatures
117	Incorrect SBI card signature
124	Incorrect output cards signature
125	Incorrect card signatures
126	N°1 exit anomaly message
127	N°2 exit anomaly message
128	N°3 exit anomaly message
129	N°4 exit anomaly message
130	Anomaly messages on several exits

 # for UCS version 1.0.4 or 2.0.3

Firmware Errors

Error codes #	Description
1	No mistake detected
2	Incorrect reading memory checking sum
3	BCC error
4	Saved memory error
5	No error in the saved memory

 # for UCS version 1.0.4 or 2.0.3

9. Reading the Encoder Input States

9.1 From the main menu shown in section 6, press key ‘3’ to read the encoder input states. The following message is displayed;

E	T	A	T	S		D	E	S		E	N	T	R	E	E	S			
E	n	t	r	e	r		l	e		n	u	m	e	r	o		d	e	
l	a		c	a	r	t	e	:		1	,	2	,	3	,	4	,		

(State of the entries - Enter the card 1, 2, 3, 4)

9.2 By pressing '1', '2', '3', or '4' tool displays continuously the state of the card inputs selected:

C		E	N	T	R	E	E		1	2	3	4	5	6	7	8	9	A	
A		T	Y	P	E				1	3	1	1	0	0	0	0	0	0	
R		A	S	P	E	C	T		E	C	F	F	D	D	D	D	D	D	
3		E	T	A	T				0	0	0	1	0	0	0	0	0	0	

(Entree = Entry Type = Type Aspect = Aspect Etat = State)

9.3 To return to start, press 'ECHAP' (escape) Key.

The symbols displayed to define the input types are:

Input type	Symbol
TE0	0
TE1	1
TE2	2
TE3	3
TE4	4

The symbols displayed to define the input aspects are:

Aspect	Symbol
Off or non-active	E
Fixed and on or active	F
Flashing (not used in UK)	C
Free input	D

The "state" line shows the instantaneous state of the inputs read by the encoder while it was scanning them for the last time before the failure.

This state can take the value 1 or 0.

10. Erasing the failure memory

10.1 From the main menu shown in Section 6, press key '4' to erase the encoder failure memory. The following message is displayed;

C	O	N	F	I	R	M	E	R		E	F	F	A	C	E	M	E	N	T
M	E	M	O	I	R	E		I	N	C	I	D	E	N	T				
			V	A	L		/		E	C	H	A	P		?				

(Confirm erasing incident memory – Validate / escape)

10.2 To cancel the request and return to start, press 'ECHAP' (escape) Key.

10.3 Key “VAL” triggers the erasing of all the failures in the memory.

The “wait message” is displayed then the action is confirmed by the following display:

	M	E	M	O	I	R	E		E	F	F	A	C	E	E			

(Memory erased)

10.4 To return to start, press ‘ECHAP’ (escape) Key.

11. Error codes generated by the tool

If faults occur when using it, the test tool will generate one of the following messages (see table below). The LCD displays the error code number followed by its label.

Error code	Displayed message	Meaning
10	Double connection in input forbidden (double connexion entrée interdite)	It is not possible to connect simultaneously a cord to each connector (15-pin and 25-pin)
12	Memory reading impossible. (lecture memoire impossible)	The encoder shows that it is impossible for it to read the failure memory.
14	Maintenance Link fault between encoder and tool (défaut liaison maintenance codeur-testeur)	After a request the tool has not received an encoder answer within expected time
16	Balise message code x unknown (Type de balise non reconnu:XX)	Presence of an unknown field code in a KVB SN message.
18	synchronization word missing or inconsistent (mot de synchronisation inconsistent ou incoherent)	Synchronization words were not found in the received message
26	Balise configuration not recognised: XX (type de balise non reconnu)	The Balise configuration transmitted in the message is not of a valid configuration (XX is equal to the decimal value of the transmitted configuration)
27	CS or CRC incorrect digital message (SC ou CRC incorrect message numérique)	The test tool has recognized a message from KVB SN but the checksum (CS) or the cyclic redundancy code (CRC) is wrong
28	Erasing memory impossible (effacement mémoire impossible)	The erasing memory order has not been carried out.
29	Maintenance Link fault between encoder and tool (défaut liaison maintenance codeur-testeur)	The frame code has not been recognised
30	Sampling fault, internal to the tool (erreur d’échantillonnage interne testeur)	There have been collisions on SPI connection.
31	Maintenance Link fault between encoder and tool (défaut liaison maintenance codeur-testeur)	Parity error
32	Sampling fault, internal to the tool (erreur d’échantillonnage interne testeur)	Granted time to sample data has gone beyond limit.

The list of error codes is not exhaustive.

Some codes rarely occur; if it happens to be the case ask the supplier.

Press the ‘ECHAP’ (‘Escape’) key if you want to clear an error message from the display.

In the case of a ‘test tool software problem’, software may no longer respond and it may be impossible to clear the display.

In this case, cut the power supply then start again (press the ‘on/off’ key twice successively).

END

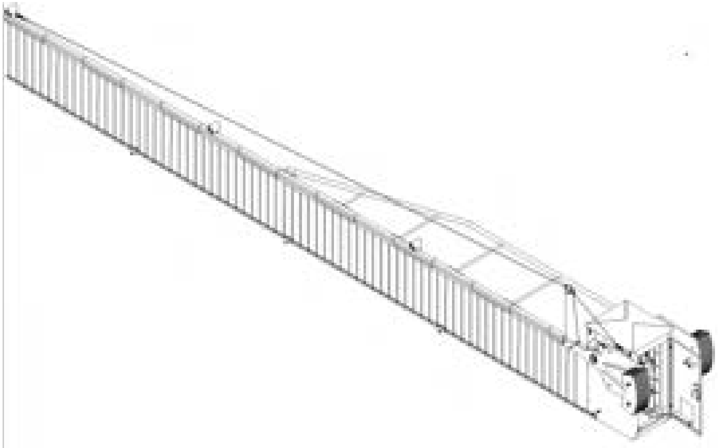


Figure 1 - Overview of the Newgate Barrier

1. Acronyms & Glossary

For the purposes of this document the following acronyms are used.

Term	Description
BL	Barrier Lower
BLSS	Barrier Limit Safety Switch
BPC	Boom Proving Contact
BR	Barrier Raised
BRSS	Brake Release Safety Switch
CRS	Centres
D1	Barrier Up Command
D2	Barrier Down Command
DFT	Dry Film Thickness
DN	Down
DNS	Barrier Down Signal
L.H	Left Hand
LCIAB	Level Crossing In a Box
LCU	Local Control Unit
LPSS	Locking Pin Safety Switch
MCB	Manual Crossing Barrier
MCB's	Miniature Circuit Breakers
MDPC	Maintainers Door Proving Contact
NGR	Newgate Rail
NR	Network Rail
OD	Object Detection
ODPC	Operators Door Proving Contact
PL	Plug
PPG	Paint System Company
PX	Proximity Sensor
R.H	Right Hand
RER	Lights On Signal
STO	Safe Torque Off
SUPPORT MEMBER	A rigid assembly used on barriers with booms 7.1m and over to support the barrier boom and prevent excessive sideways movement.
UPS	Uninterruptable Power Supply

2. Technical Data: Booms

Construction : Steel Frame, Aluminium Arm

Available Spans:

Single Sided

- 3600mm
- 4100mm
- 4600mm
- 5100mm
- 5600mm
- 6100mm
- 6600mm

Double Sided

- 7100mm
- 7600mm
- 8100mm
- 8600mm
- 9100mm

All Spans 7100mm+ are fitted with straining wire and support member.

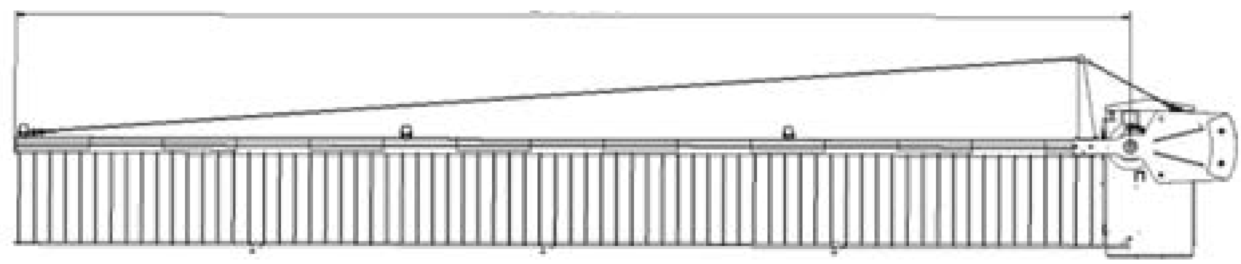

Figure 2 – Span (Side View)

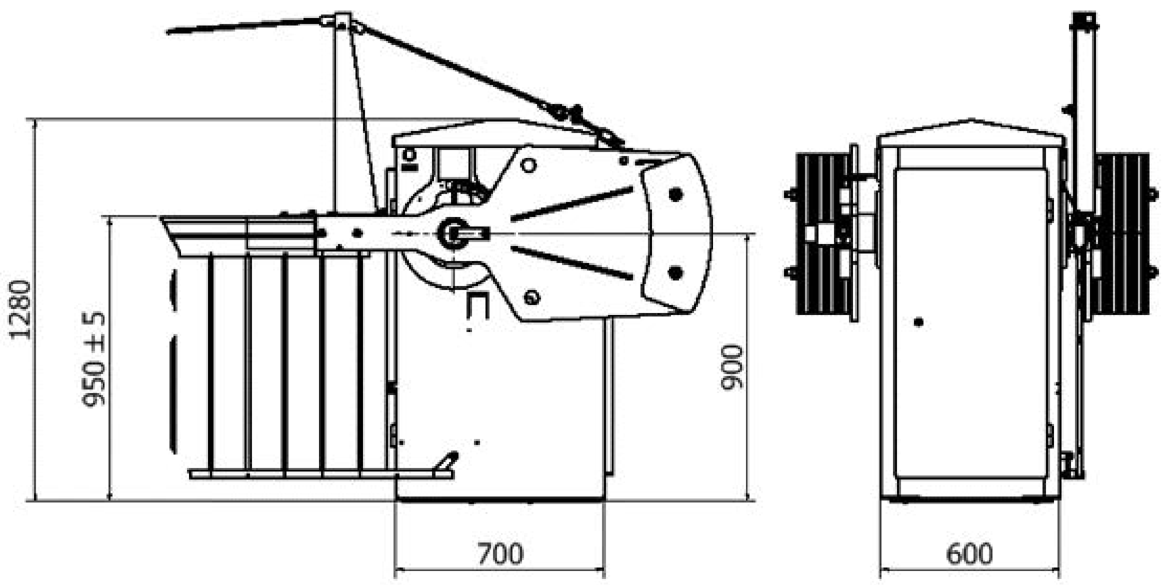
Booms are powder coated white RAL9010 and are fitted with 600mm long red (BS381C-537) vertical stripes. 50mm wide red and white reflective tape is fitted either side of the boom. A-Frame if fitted is powder coated white RAL9010.

3. Technical Data: Barrier Machine

Power Requirements	110v 1ph 50Hz
Fused Rating	20 amps
Operation Movement	0-85° (Horizontal to Vertical)
Time of Operation	8 to 10 seconds (Lower)
	6 to 10 seconds (Raise)
Handing	R.H. or L.H. (Optional)
Manual Operation	By Manual Pump
Weight	475 kg (Barrier excluding Weights, Side arms & Booms)
	85 Kg (each sidearm)
	9.5 Kg(each weight)
Dimensions	



IP Rating	IP56
Control System	Various (as specified)
Storage Temperature	0 to +50 °C (do not store outside for long periods of time)
Operating Temperature Range	-25 to + 40 °C (external ambient)
Noise Level	Less than 70 Db

NOTE: The Barrier Machine is fitted with safety interlocks to the operators and technicians' doors to prevent the machine from running when either door is open.

Should this be bypassed for fault diagnostics and testing setup purposes only, the areas shown in figures 3 & 4 should be treated with extreme caution.

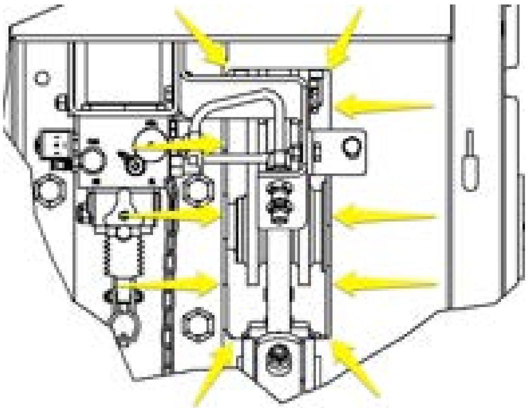


Figure 3 – Danger Zones

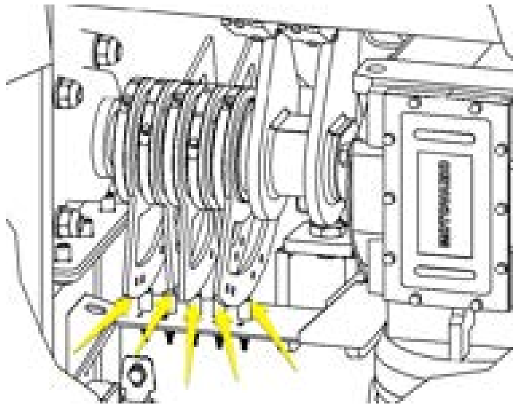

Figure 4 - Proximity Sensors

4. Product Functionality and System Operation

4.1 Product Functionality

The Newgate NGR18000 barrier machine consists of a rigid pressed steel frame containing an electric motor and gearbox, transmitting drive directly to the output shaft; the shaft is attached to the frame by self-aligning ball bearings.

The movement of the shaft is controlled via the position limit cams and proximity sensors. The proximity limit cams are set in house to control:

- Upper & Lower limits of the barrier movement.
- Fast/Slow speed changeover positions.
- Lights on feedback signal to control system.

The position limit cams are factory set, if adjustment is required to satisfy carriageway cross fall or camber, design information to be supplied to manufacture for machine to be factory set as require.

Either a single or pair of side arms are attached to the output shaft, holding the bias weights, boom, straining wire and support member.

The barrier can be operated manually in the event of a power failure by opening the rear access door, disengaging the motor brake and using the hydraulic hand pump to operate the boom

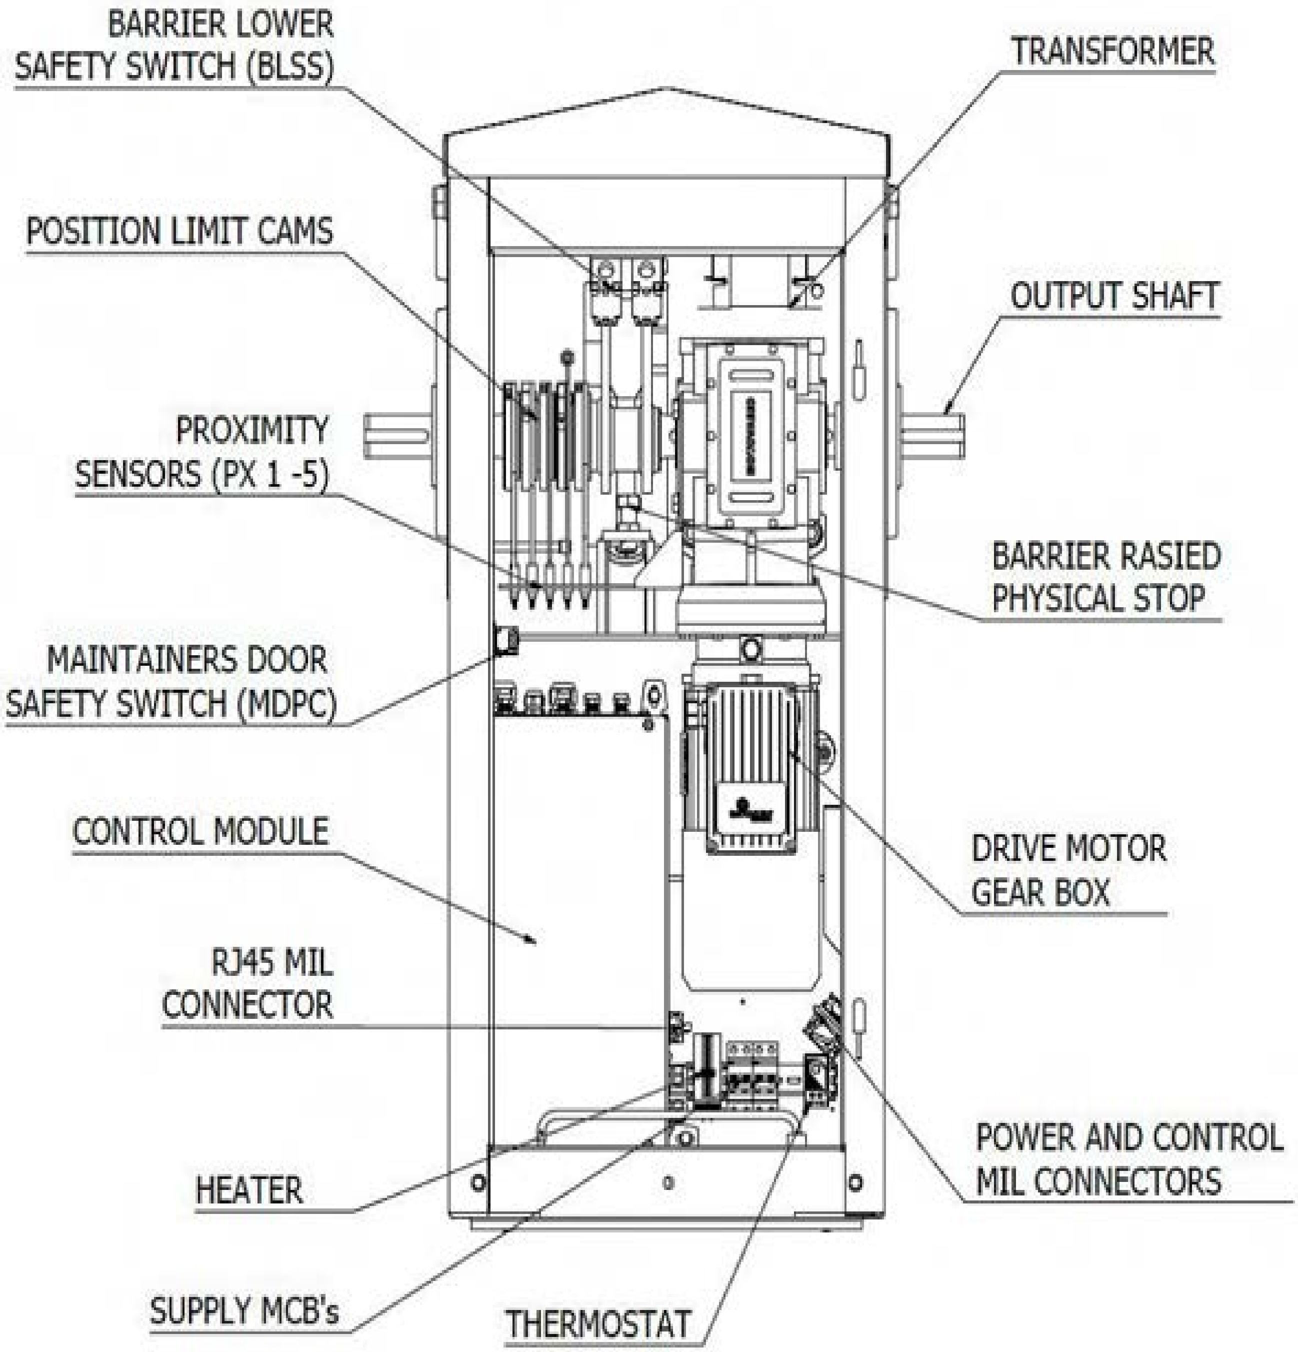

Figure 5 - View with Technician's door removed

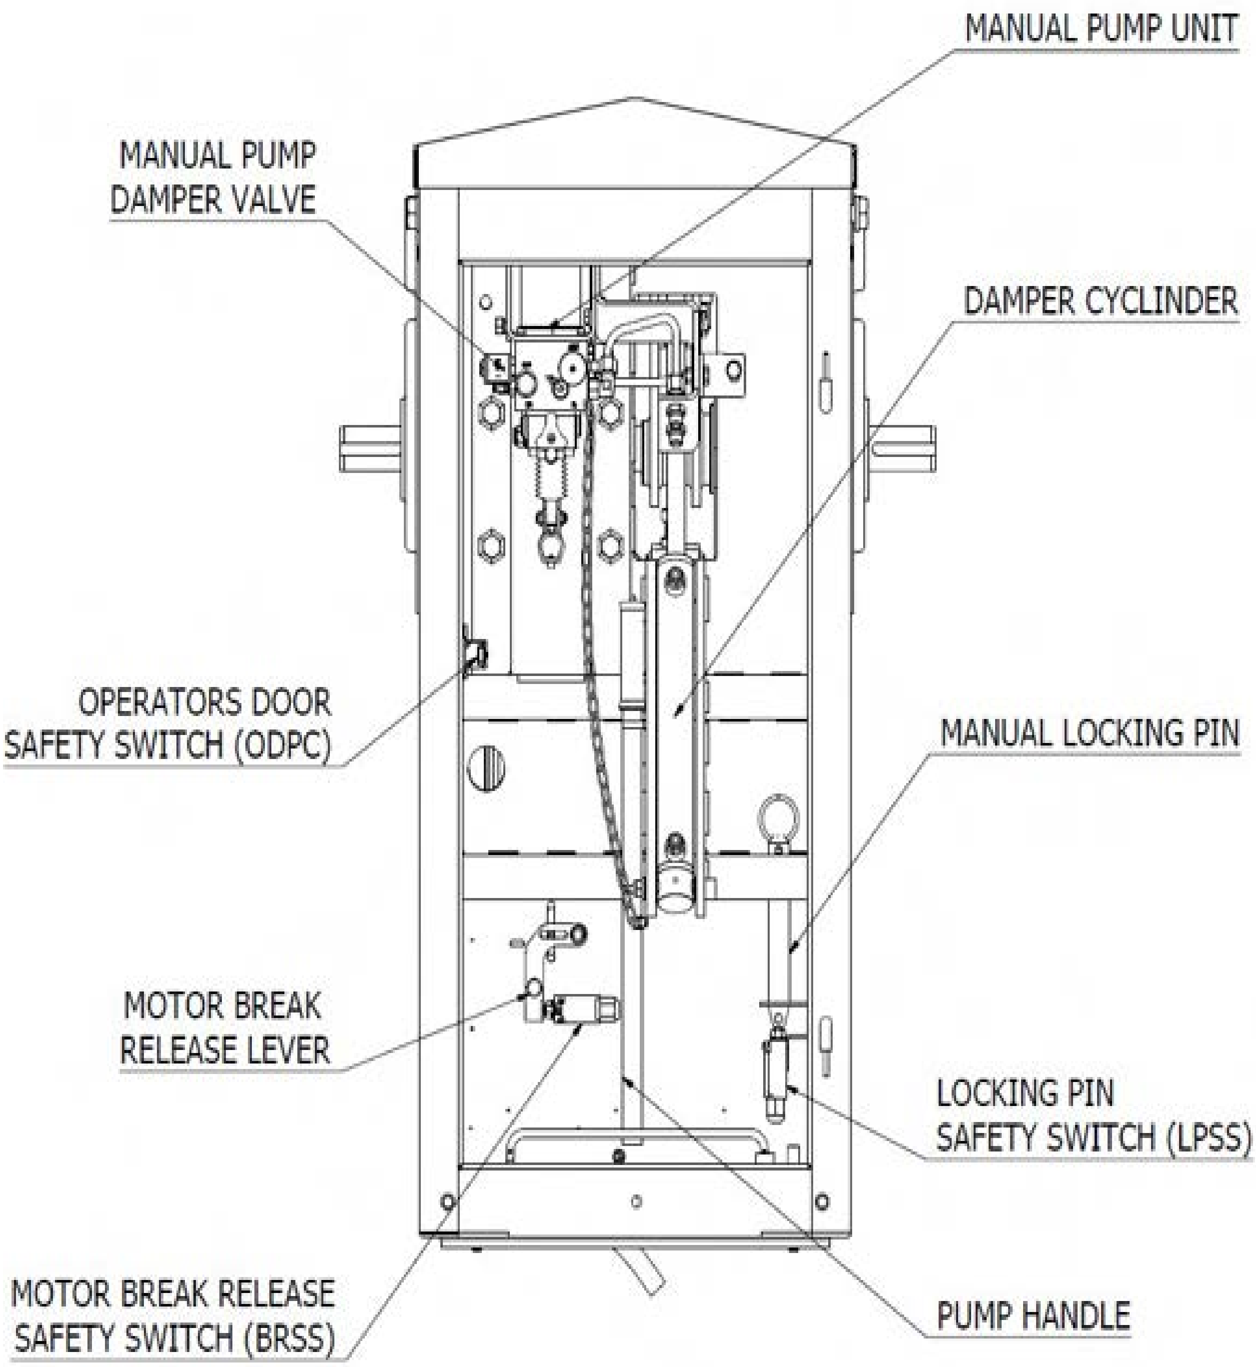

Figure 6 - View with Maintenance door removed

4.2 Product Compatibility

The Newgate Rail (NGR) Barrier machine housing is designed to be directly replaceable with existing BR843 machines. The standard stud 500mm x 440mm centres and foundation requirements are the same.

For seamless repairs original NGR booms and boom braces should be used. BR843 boom braces are not compatible with the NGR18000 barrier machine.

4.3 System Operation

The motor is controlled by the frequency inverter unit which provides the following functions for the barrier machine enabling consistent and reliable operation:

- Separate raise and lower acceleration / deceleration time periods.
- Separate fast and slow speed changeover angles thus ensuring a smooth transition to the raised and lowered rest positions.

The acceleration, deceleration, fast and slow speeds are determined by the fixed parameters in the inverter settings, pre-set for the barrier option required.

The safety controller logic performs the barrier control operation via the inputs and outputs assigned to the controller.

The default rest state of the barrier is in the raised position awaiting a lower signal from the external control system.

4.4 Lowering Operation

a) Lower signal received (D2), barrier accelerates to the fast speed setting.

b) Lights On angle position ≤ 40º detected by the Proximity Sensor PX3, Lights On interlock interface signal (RER) to external control system enabled.

c) Fast/slow speed changeover angle position detected by Proximity Sensor PX4, barrier decelerates to the slow speed setting.

d) Lowered angle position detected by the Proximity Sensor PX2, barrier again decelerates to the lowered stop position.

e) Barrier angle ≥ 4º, barrier lower safety limit switches BLSS 1&2 actuated, Safety Down interlock to external control (DN) activated and timer initiated in controller logic, after time period motor inverter STO interlock removed, inverter inoperable.

f) Barrier Down interlock to external control (DNS) activated.

4.5 Raise Operation

a) Raise signal received (D1), motor inverter STO interlock initialised, inverter operable.

b) Timer initiated in safety controller logic, after 0.5 seconds the barrier accelerates to the fast speed setting.

c) Lights Off angle position ≥ 40º detected by the Proximity Sensor PX3, Lights Off interlock interface signal (RER) to external control system enabled.

d) Fast/slow speed changeover angle position detected by Proximity Sensor PX 5, barrier decelerates to the slow speed setting.

e) Barrier Raised angle position detected by the Proximity Sensor PX1, barrier again decelerates to the Raised stop position.

f) Barrier Up interlock to external control (UP) activated.

g) Barrier Down interlock to external control (DNS) activated.

4.6 Additional Control System Interface Signals

a) Boom Proving (BPC) – Barrier boom in position on boom adapter, Boom Proving interlock contact to external control system activated.

b) Door Proving (ODPC+MDPC) – Barrier main casing access doors closed, Door Proving contact to external control system activated.

c) Boom Lights – The boom lights operation are controlled from the external control system.

5. Barrier Control Module and Barrier Mounted Equipment

5.1 Barrier Control Module

The Control Module is designed on a plug and socket basis (PL1-7) (see Figure 4 for location) to enable the whole Control Module assembly to be removed and replaced without the need to disconnect any cables from the termination points.

This is aimed at reducing the down time of the barrier operation should there be a need to replace the Control Module assembly.

The function signals to the barrier (Lower, Raise, and- Boom Lights) are controlled externally and the interface signals for specific positions of the barrier during the operation are transmitted to the external equipment.

Electrical control equipment mounted within the barrier casing, external to the Control Module, act to provide a safe, accurate and consistent function for the barrier.

The position limit cams are pre-set to obtain the optimum performance of the barrier and should not be adjusted.

5.2 Barrier Mounted Equipment and Function

This equipment comprises of the following items:

Braked Motor Assembly

Used to drive the barrier machine gearbox allowing the boom to be raised and lowered. The assembly also provides locking of the boom in the raised and lowered rest positions.

Proximity Sensors (PX1-5)

PX1 – Barrier not Raised

To detect whenever the barrier is not in the raised position.

Initiates the raise deceleration time period which is pre-set in the inverter parameters

PX2 – Barrier not Lowered

To detect whenever the barrier is not in the lowered position.

Initiates the lower deceleration time period which is pre-set in the inverter parameters.

PX3 – Lights On

To detect whenever the barrier is between 0º - 40º.

PX4 – Barrier Lower Fast Speed

To detect when the barrier inverter is to be switched between fast and slow speed during the lower cycle.

PX5 – Barrier Raise Fast Speed

To detect when the barrier inverter is to be switched between fast and slow speed during the raise cycle.

Lowered Safety Limit Switches (BLSS 1 & 2)

To detect when the barrier is between 4º - 0º in order to output safety signal for Barrier Down.

Operator Door Safety Switch (ODPC)

Used to isolate barrier control preventing the machine to be operated when the operator's door is open.

Maintainer Door Safety Switch (MDPC)

Used to isolate barrier control preventing the machine to be operated when the maintainer's door is open.

Locking Pin Safety Switch (LPSS)

To isolate barrier control when the locking pin is not in the home stored location.

Motor Brake Release Safety Switch (BRSS)

To isolate barrier control when the motor brake override lever is not in the normal operating position.

Manual Pump Damper Valve

This valve, when energised causes the hydraulic oil to bypass the manual pump cylinder.

6. Handling

6.1 Transporting

For ease of transportation, the barrier pedestal is despatched with the boom and if applicable A frame detached.

The boom side arms are secured in the vertical position with pins to lock them in place.

The assembly is transported, mounted to a pallet (for stability), due to the weight of the item a local risk assessment should be carried out and a lifting plan in place before lifting the equipment on site.

The use of a lifting appliance e.g. fork truck or small crane is strongly recommended.

6.2 Lifting

The barrier should always be lifted using the appropriate lifting equipment.

To lift remove the four M20 bolts around the top of the barrier pedestal (highlighted) and replace with M20 Lifting eyebolts to DIN580 or equivalent rated to 830kg slinging at 45°.

Attach 4 legged lifting chains (7mm chain) rated to 3100kg to lifting eyes.

NOTE: See below table for maximum machine weight, ref 9100mm = 947kg.

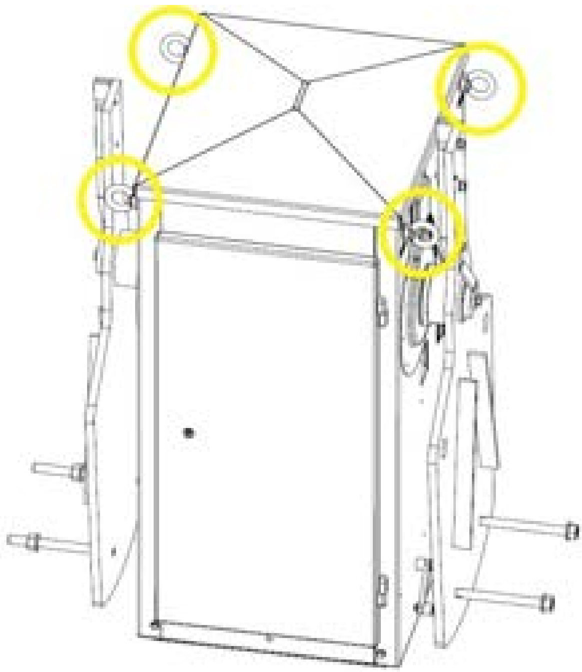

Figure 7 – Lifting Eyes

Boom Assembly Length	Estimated Total Assembly Weight (kg)	Boom Weight (kg) *=inc boom brace	Pedestal with side arms and weights (kg)
3600mm	599	28.5	570
4100mm	621	32	589
4600mm	643	35	608
5100mm	665	38	627
5600mm	687	41	646
6100mm	719	45	674
6600mm	751	48	703
7100mm	869	65*	804
7600mm	909	67*	842
8100mm	943	72*	871
8600mm	984	75*	909
9100mm	1025	78*	947

7. Replacement of Damper Cylinder or Hydraulic Hose

7.1 Isolate the barrier machine at the LXP fuse links.

7.2 Visually check for signs of oil seepage.

7.3 Remove barrier machine locking pin.

7.4 Release plunger on manual hand pump.

7.5 Release motor brake leaver and secure in manual position.

7.6 Remove and replace Damper Cylinder or Hydraulic Hose.

In order to take the strain off of the “Damper Cylinder Assembly”, and ease its replacement the barrier locking pin should be removed and the barrier lowered by hand to the ¾ raised position.

7.7 Top up hydraulic oil.

7.8 Check hand pump for ease of operation.

7.9 Toggle pump direction leaver to the left to raise the boom.

7.10 Manually pump to raise barrier.

7.11 Manually raise and lower the barrier a minimum of three times. Leaving the barrier in the raised position.

7.12 Recheck oil level again.

7.13 Recheck for leaks from cylinder pipes and couplings.

7.14 Reconnect machine to power supply.

7.15 Raise and lower the barrier a minimum of three times on power. Leaving the barrier in the raised position.

7.16 Check for leaks from cylinder pipes and couplings.

7.17 Check oil level is correct.

7.18 Dispose of any contaminated items as per NR Environmental policy.

8. Barrier Cage Removal, Replacement and Clearance’s

Front Guard Removal

8.1 Isolate barrier machine power from supply.

8.2 Switch supply MCB's to off position. Check with a multi-meter there is no mains supply from the output of the circuit breaker to check it is switched off before proceeding with the work.

8.3 Remove M8 bottom fixings and side fixings with 13mm A/F spanner from front guard. (See Figure 8).

8.4 If fitted remove Bolt on Infill, remove fixings M8 fixings using 13mm A/F spanner.

8.5 Remove bolts on infill.

Figure 8 – Infill bolts

8.6 Carefully remove Top M20 fixing with 30m A/F spanner, note guard is now loose. (See Figure 9).

8.7 Re-fitting is the reverse of removal, torque M8 fixings to 29Nm.

8.8 Reconnect the power supply.

Figure 9 - Top M20 fixing

<u>Side Arm Guard Removal</u>

8.9 Isolate barrier machine power from supply.

8.10 Switch supply MCB's to off position. Check with a multi-meter there is no mains supply from the output of the circuit breaker to check it is switched off before proceeding with the work. (See Figure 10).

Figure 10 – Isolation MCB's

8.11 Lift sliding door panel vertically until it is clear of door guides, the spring-loaded plungers will need to be retracted to allow the door to pass by the panel support brackets and enable complete removal. (See Figure 11).

Figure 11 - Sliding Door Panel

8.12 If fitted remove Bolts on Infill, remove fixings M8 fixings using 13mm A/F spanner.

8.13 Remove bolts on infill. (See Figure 12)

Figure 12 – Infill Bolts

8.14 Remove M8 bottom fixings and side fixings with 13mm A/F spanner from front guard. (See Figures 13 & 14)

Figure 13 – Bottom Fittings

Figure 14 – Bottom fittings 2

8.15 Carefully remove Top M20 fixing with 30m A/F spanner, note guard is now loose.

Figure 15 – Top M20 Fixings

Remove front guard.

8.16 Remove Side Arm Guard by removing two M8 fixings fitted either side of barrier machine. Use 13mm A/F spanner or 13 A/F socket. (See Figure 15)

Figure 16 – M8 Side arm fixings

8.17 Remove remaining M20 fixings with 30mm A/F spanner. (See Figure 17)

8.18 Carefully lift machine guard away from barrier machine.

Figure 17 – Remaining M20 Bolts

8.19 Re-fitting is the reverse of removal, torque M8 fixings to 29Nm.

8.20 Reconnect the power supply.

END

1. Balise

All Balise are the same pieces of equipment but can be used in one of two modes.

The most common is the fixed mode configuration; this is where the Balise contains a programme applicable to its location and has no physical link with any other equipment.

The second type is the switchable configuration which is only used at locally monitored level crossings on the Cambrian. In this configuration the Balise contains a permanent programme applicable to its location which can be temporarily suppressed.

The suppression is in the form of an input received via a fixed cable link from a controlling Lineside Encoder Unit located at the crossing.

The train reads the Balise in either configuration by telepowering. This is where the train transmits a signal into the Balise, the signal energises the Balise and allows the same antenna to read the information stored in the Balise.

2. Fixed Mode Balise

These are passive programmable devices that are only energised and read by the systems fitted to the train.

Balise groups are arranged in the following configurations, a single balise, two Balise and four Balise. N_PIG=0 is always located at the higher Kilometric number.

Balise groups are used to pass the following information to trains:

<u>General</u>

a) Odometry.

b) Direction of travel.

c) Stop if in Shunt Mode.

d) Stop if in Staff Responsible Mode.

e) Text Messages, “AOCL Ahead, ABCL Ahead, TMOB Ahead”.

f) Awakening function.

Transition Area

g) Registration.

h) Connection.

i) Annunciation.

j) Annunciation Boarder.

Balise Groups BG12001 and BG12003 at Sutton Bridge consist of four Balise and are described as Duplicated Balise; these groups consist of two pairs of Balise containing the same information.

They are duplicated because of their critical function in the transition process. As long as the train has read one pair in each group, no error message is generated for transmission to the RBC and it transitions correctly.

Because no error message is transmitted it is necessary to manually test the operation of the Duplicated Balise Groups as part of the annual maintenance regime.

Balise Groups BG12000 and BG12002 at Sutton Bridge each consist of a single Balise. They are provided to reset and synchronise the on board odometry before a train entering the Cambrian reads BG12001.

These two Balise Groups are identical in terms of the effect they have on the on board systems and are duplicated for redundancy purposes.

A train entering the Cambrian Line would be unaware of the existence of Balise' so should a fail to read occur, no error message is transmitted from the train. It is therefore necessary to manually test the operation these Balise Groups as part of the annual maintenance regime.

3. Automatic Wheel Diameter Calibration

For a train to accurately calculate its position along the route, it is critical that the on-board systems have accurate information of wheel diameter, this can be achieved in one of two ways.

The first is by manual measurement of the wheel which is carried out as part of the train's normal maintenance programme and the second is carried out automatically whilst the train is in service.

Using automatic calibration, the train counts the revolutions of the wheel whilst travelling over a known distance. Having this information allows the on board systems to calculate the wheel diameter.

The advantage of the automatic calibration over manual calibration is that it does not require a maintenance intervention to carry out the task, it is more accurate and the interval between updates of wheel diameter is more frequent.

On the Cambrian certain Balise Groups are designated for Automatic Wheel Calibration. This makes the distance between these groups critical to achieving accurate wheel diameter calculations.

The identity of Balise Groups at the start and termination of the calibration areas are stored in the on-board system, and markers are provided track side at the designated Balise Groups to assist in accurate calibration of the N_PIG=0 Balise.

4. Switchable Balise

Balise in this configuration are only provided on the approach to locally monitored level crossings. The purpose of these Balise is to impose a pre-set temporary speed restriction when the conditions to illuminate the Drivers Crossing Indicator (DCI) white flashing indication are not met.

The TSR Balise has data permanently programmed into them in the same way as a fixed mode Balise.

The TSR message is suppressed when the conditions to illuminate the DCI white flashing indication are met.

To effect the suppression an output is fed from the level crossing controlling relays via a Lineside Encoder Unit (LEU) to the TSR Balise.

The LEU acts as an interface between the crossing relays and the Balise, this converts the relay logic into a message transmitted via a cable connection to the TSR Balise.

The Balise responds to messages and this response forms part of the health monitoring available at the LEU.

An output of the LEU health monitoring is used to operate a BR930 series relay, the relay is energised when the LEU is healthy and de-energised when it is not healthy.

Contacts of this relay are used in the DCI control circuits, when energised it is possible for the DCI to display a white flashing indication if all other conditions are met. If the relay is de-energised the DCI is only be capable of displaying a red flashing indication.

5. Positioning of Balise

a) On the signalling plan the kilometric positions of the N_PIG=0 and N_PIG=1 balise are shown in the tables and the spacing is always shown as the 3m nominal. The precise location of the N_PIG=1 balise is less relevant whether it is used for calibration or not.

b) N_PIG=0 is always the ‘reference’ location for the group and shall be maintained at the designed location shown on the signalling plan +/- 30cm.

c) For the Cambrian the nominal design spacing between individual Balise within a group is 3m.

The absolute minimum spacing is 2.6m and the maximum is 5.6m for reliable operation.

6. Balise Brackets

Individual Balise brackets are designed for the various types of sleepers and rail fixings in use on the Cambrian.

All brackets are designed to vertically position the Balise at the correct height relative to the rail head.

When mounting a Balise on steel sleepers an additional spacer is required between the bracket and the Balise. The spacer is required to increase the air gap between the top of the sleeper and base of the Balise to confirm correct operation of the Balise.

END

Includes:	EFOY - Fuel Cells
Excludes:	All other types of Fuel Cell

Do not smoke in the vicinity of the Pro fuel cell or fuel cartridge.

Protect from heat and ignition sources. Methanol is highly flammable!

Do not inhale exhaust gases directly for prolonged periods.

Do not touch leaked methanol.

The EFOY Pro fuel cell shall not be opened.

Gloves and eye protection shall be worn during this task.

System Overview

1. Connections - General

1. Connection for charge line.
2. Connection for operating panel.
3. Connection for data interface.
4. On/Off Reset Button.
5. LEDs.
6. Connection for exhaust hose and fill opening for EFOY service fluid.
7. Connectors for EFOY fuel cartridges.
8. Cooling inlet (reverse).
9. Warm-air outlet and connection for off-heat duct.

5. Operation via the Operating Panel

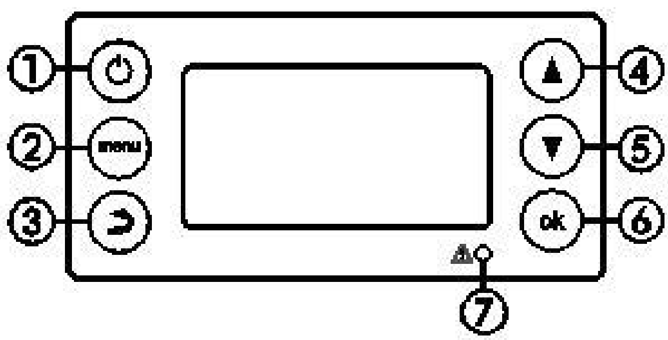

Figure 3 – Operations Panel

5.1 Buttons and symbols on the operating panel Buttons/LEDs.

No.	Symbol	Description
1.		Switch EFOY Pro fuel cell on/off.
2.	[menu]	Display the main menu.

No.	Symbol	Description
3.	[⮌]	Scroll back one level in the menu.
4.	[▲]	Scroll up one line in the display.
5.	[▼]	Scroll down one line in the display.
6.	[ok]	• Open the selected menu. • Confirm a selection.
7.		Red LED lights up to indicate a fault.

Table 5 – Button Meanings

5.2 Symbols on the Display.

The display shows different symbols depending on the operating status and operating mode of the EFOY Pro fuel cell:

Symbol	Description
	Current battery voltage.
	Current charging current of the EFOY Pro fuel cell.
	Fill level of the fuel cartridge. The fuel gauge for the fuel cartridge is just an indicator and calculates the methanol consumption. The FS1 fuel cartridge sensor should be used to measure the actual fill level. The fuel cartridge should only be replaced once it has been completely emptied.
	A cluster icon is displayed for EFOY Pro devices that run in parallel (Not Used on NR Equipment).
	If want to operate the EFOY Pro fuel cell using an external controller, the external control function shall be enabled (see "External control" clause 6.4). If this is not enabled, a padlock symbol appears.
	If the external control is switched on, an open padlock appears at the bottom right of the display.
RC	If you have switched external control on and the device is in "Remote Control" mode, "RC" (Remote Control) appears at the bottom right of the display.
LiFe	Lithium iron phosphate (LiFePO4) was selected as battery type. “LiFe” appears at the top right of the display.

Symbol	Description
	EFOY GO! was selected as battery type. “GO!” appears at the top right of the display.
	The altitude was set above 1500 meter. An icon appears at the bottom right of the display.
	MODBUS RTU was selected as communication protocol. “M” appears at the bottom right of the display.

Table 6 - Symbols

6. Operating Modes

The EFOY Pro fuel cell can be operated in one of the following modes:

- Automatic.
- Manual On.
- Manual Off.
- External control.
- Hybrid.

6.1 Automatic

Automatic mode starts as soon as you connect the device to the battery.

The device monitors the battery voltage independently.

The EFOY Pro fuel cell switches on automatically if the battery voltage drops below 12.3 V / 24.6 V (factory setting: Lead batteries).

The battery is then charged until the cut-off threshold of 14.2 V / 28.4 V is reached (factory setting: Lead batteries).

When the device is started, it goes through a start phase, which might last up to 20 minutes. It only reaches its full rated output after this phase.

During normal operation, the EFOY Pro fuel cell briefly interrupts power generation several times each hour.

A charging current of 0.0 A is displayed when this occurs. This interruption lasts maximum 30 seconds.

If the device fails to start, check that the cap is not still attached to the exhaust hose connector. Remove the cap.

To optimise the battery maintenance, the charging current should not be stopped abruptly when the cut-off threshold is reached.

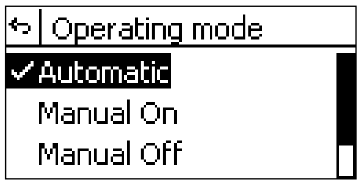
For this reason, the EFOY Pro fuel cell continues charging the battery for up to three hours at a reduced current after the configured cut-off threshold is reached (factory default lead batteries: 14.2 V / 28.4 V).

The length of the recharging period depends on the battery voltage and power consumption.

6.2 Manual On

You can switch the device on manually if the battery voltage is below 13.2 V / 26.4 V (Lead batteries).

a) Press ⏻ on the operating panel, or select "Operating mode" in the main menu. The operating mode selection appears.



b) Select the "Manual On" operating mode.

c) Press [ok] to confirm your selection.

After the start phase, the device is then in "charging mode".

The device operates independently of the configured switch-on voltage, and charges the battery until the cut-off threshold is reached.

$(U_{batt} > 14.2\ V / 28.4\ V \text{ and } I_{off} < 4.0\ A / 2.0\ A)$

After reaching the switch-off threshold the EFOY Pro fuel cell should switch into automatic mode.

NOTE: *The EFOY Pro fuel cell can only start if it is connected to an intact battery and a filled fuel cartridge. The EFOY Pro fuel cell does not switch on if the battery is damaged or has been deeply discharged.*

If the device fails to start, check that the cover lid is not still attached to the exhaust hose connector. Remove the cover lid.

6.3 Manual Off

To protect the components, the device should not be switched off until it has been running for at least 30 minutes since it was started.

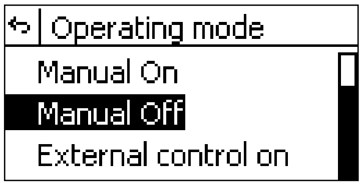
If the device is switched off before this period has elapsed, it should continue running for the remainder of the required running time.

The message "Shutdown procedure" is shown on the display. Do not disconnect the fuel cartridge or battery during the shutdown procedure.

The battery protection and automatic antifreeze functions remain active after the device is switched off.

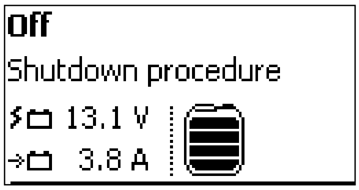
a) Press on the operating panel, or select "Operating mode" in the main menu. The operating mode selection appears.

b) Select the "Manual Off" operating mode.



c) Press [ok] to confirm your selection.

d) Wait until the shutdown procedure has finished and "Shutdown procedure" is no longer displayed on the info screen.



The EFOY Pro fuel cell shuts down in a controlled manner when you press [ok]. This might take some time, to check that all protective features are applied.

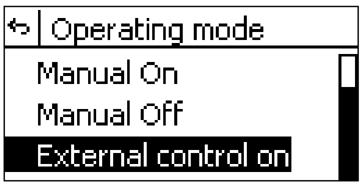
6.4 External Control

The EFOY Pro fuel cell can also be controlled externally. In that case, the automatic charge control mechanism should be partly or totally deactivated.

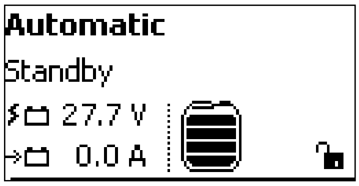
For an external control the operation mode "External control" shall be enabled.

a) Press on the operating panel, or select "Operating mode" in the main menu. The operating mode selection appears.

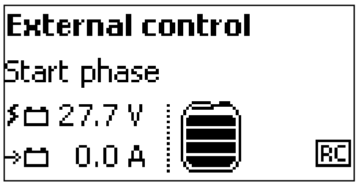
b) Select the "External control on" operating mode.



c) Press [ok] to confirm your selection.



An open padlock is displayed at the bottom right of the display.



If the controller now receives an external signal, e.g. on Pin 7 (Data Interface), "RC" (Remote Control) is displayed at the bottom right of the display.

If you have not enabled external control, a closed padlock is displayed at the bottom right of the display when an external signal is being received.

NOTE: *Incorrectly set operating parameters might damage the device. This could nullify your warranty. Only use the precise values permitted for the battery parameters and battery protection settings.*

6.5 Remote On / Off

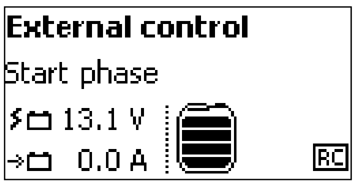
The EFOY Pro fuel cell can be switched on or off externally using one of two methods. One option is by using a switching contact on Pin 7 at the Data Interface plug, e.g. a solar charger.

The second option is a software signal. (See Connections Section 3 for the pinning).

The "External control" operating mode shall be enabled (see External control 6.4).

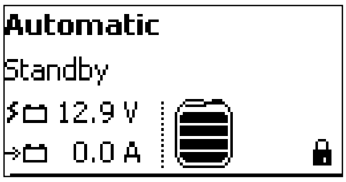
Remote on/off signal via Pin 7 (Data interface)

An open padlock is displayed at the bottom right of the display.



If the EFOY Pro receives an external positive voltage signal on Pin 7, "RC" (Remote Control) is displayed at the bottom right of the display.

The EFOY Pro starts charging, regardless of the switch-on voltage and charges the batteries until the set switch-off parameters are reached.



If you have not enabled external control, a closed padlock is displayed at the bottom right of the display when an external signal is being received.

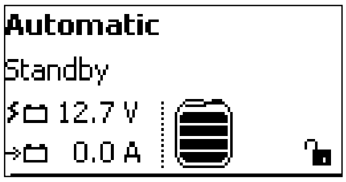
If the external signal on Pin 7 is always active, the EFOY Pro starts when the battery voltage is below 13.2 V / 26.4 V (Lead batteries) or 14.0 V / 28.0 V (LiFePO4) and stop when the switch-off voltage is reached.

The charging starts again at 13.2 V / 26.4 V (Lead batteries) or 14.0 V / 28.0 V (LiFePO4). The EFOY Pro does not stop charging in this operation until removing the external signal on Pin 7.

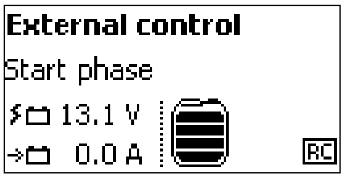
If the external signal is removed (off), the EFOY Pro charges the battery until the set switch-off parameters are reached and switch back in automatic mode.

Remote on/off signal via software command

An open padlock is displayed at the bottom right of the display.



If the EFOY receives a software signal via SIO command REMOTE ON or via Modbus address 41030, "RC" (Remote Control) is displayed at the bottom right of the display.



The EFOY Pro starts charging, regardless of the switch-on voltage and charge the batteries until the set switch-off parameters are reached.

The signal only has to be sent once. The EFOY Pro completes a charging cycle and switch off if the set switch-off parameters have been reached.

After the charging cycle the EFOY Pro switches again into automatic mode.

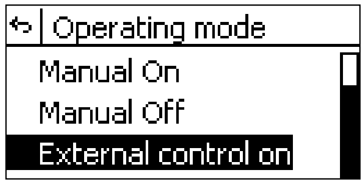
In the case of a software command, the charging cycle can be stopped by sending the SIO command REMOTE OFF or via Modbus address 41030.

6.6 Hybrid

The EFOY Pro can be set into Hybrid mode by a voltage signal or a software control. In this operation mode all parameters are disabled, like switch-on voltage or battery protection.

Only the frost protection mode is an exception, this re-mains enabled.

The "External control" operating mode shall be enabled (see External control 6.4).



The hybrid mode has to be separately activated.

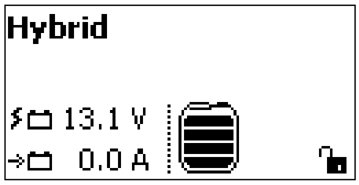
Activation via voltage signal:

Connect Pin 4 (GND, Ground) or the negative battery pole with Pin 8 (Hybrid).

Activation via software control:

Send at least every 15 seconds the SIO command HY-BRID or Modbus address 42002 Hybrid to the EFOY Pro fuel cell.

The operation mode “Hybrid” displays, and the open padlock shows at the bottom right of the display.



To start and stop the EFOY Pro fuel cell a positive voltage signal shall be connected to Pin 7 (Remote On) or via software SIO command REMOTE ON/OFF or Modbus address 41030 (see Remote On / Off Clause 6.5).

The battery voltage shall not exceed the set value switch-off voltage (Hybrid).

If the voltage signal on pin 7 or the “Remote ON” software commands is continuous, the EFOY Pro fuel cell charges the battery continuously in full and part load mode as a constant voltage (CV) charger.

7. Automatic Anti-Freeze Feature

The device has an intelligent automatic antifreeze feature.

This operating status switches on automatically as soon as the temperature drops below +3 °C / +37.4 °F.

This prevents the device from freezing. If the device is operating in antifreeze mode, the message "Antifreeze" is shown in the second line of the display.

NOTE: *The automatic antifreeze feature only works when the fuel cell is connected to a filled EFOY fuel cartridge and an intact battery.*

For a five-month winter period in Central Europe, the device requires approx. 10 litres / 2.64 gallons of methanol in antifreeze mode.

NOTE: *Charging Lithium (LiFePO4) batteries is not always possible at temperatures below 0 °C. The instructions from the battery manufacturer should be observed.*

8. Battery protection

The EFOY Pro fuel cell has automatic battery protection when the EFOY Pro fuel cell is switched off.

Battery protection is enabled automatically if the battery voltage (Lead-batteries) drops below 11.2 V / 22.4 V for more than 15 minutes.

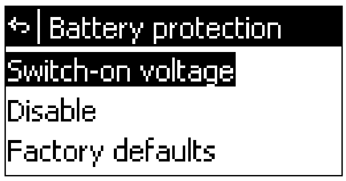
"Battery protection" mode ends as soon as the voltage reaches 13.2 V / 26.4 V.

If the battery protection is activated, the standard switch-off criteria are ignored.

The battery protection function provides deep discharge protection for the battery, even when the EFOY Pro fuel cell is switched off and does not take over the charging function.

8.1 You can select the following menu options in the "Battery protection" menu:

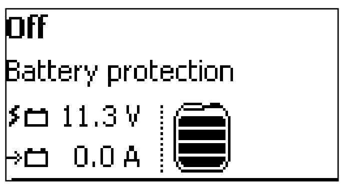
- Switch-on voltage.
- Enable/Disable.
- Factory defaults.



This option allows you to undo all the battery protection settings.
Press [ok] to confirm or [] to cancel.

8.2 If you want to switch off the EFOY Pro fuel cell after the battery protection function has started, press.

The function is re-enabled automatically when the device is switched on or is operated in automatic mode.



8.3 Check your system if the fuel cell repeatedly switches back to battery protection.

Either the battery has already been damaged or too much energy has been discharged.

Battery protection only works if a full EFOY fuel cartridge is connected.

9. Battery Value Ranges

Lead-acid, -gel & AGM batteries	**ID**	**Factory defaults**	**Min.**	**Max.**
Battery protection (12 V)	46	11.2 V	10.5 V	12.0 V
Battery protection (24 V)	47	22.4 V	21.0 V	24.0 V

LiFePO4 batteries	**ID**	**Factory defaults**	**Min.**	**Max.**
Battery protection (12 V)	48	11.0 V	10.5 V	12.5 V
Battery protection (24 V)	81	22.0 V	21.0 V	25.0 V

Permitted value ranges for EFOY GO!	**ID**	**Factory defaults**	**Min.**	**Max.**
Battery protection	14	11.2 V	10.5 V	12.5 V

Table 7 – Battery Ranges

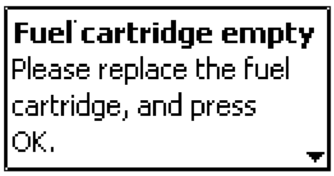
10. Fuel cartridges

Completely empty fuel cartridges can be disposed of with your plastic waste.

Partly full or damaged fuel cartridges shall be treated as hazardous waste and returned to the supplier for reuse.

10.1 Fuel Cartridge Indications

When the fuel cartridge is empty, the yellow LED on the device flashes and the red LED on the operating panel. "Fuel cartridge empty" also appears on the operating panel.

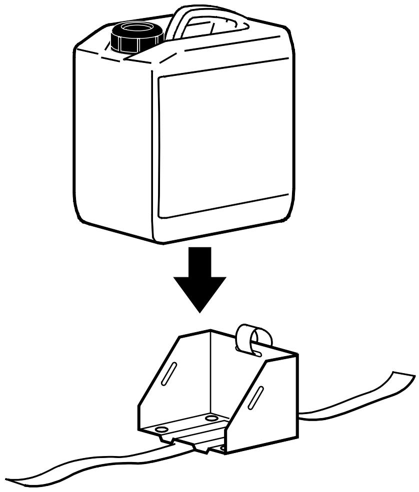


The fuel cartridge can be changed while the device is in operation.

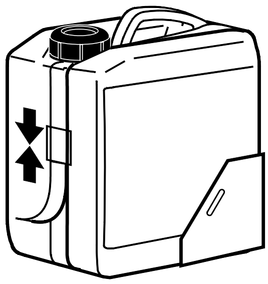
EFOY fuel cartridges are intended for single use only and cannot be refilled.

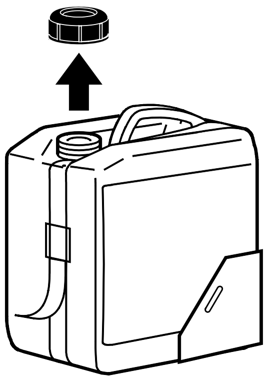
10.2 Inserting the fuel cartridge

a) Insert a new, full, and sealed fuel cartridge into the fuel cartridge holder (if fitted).



b) Fasten the belt on the fuel cartridge holder.





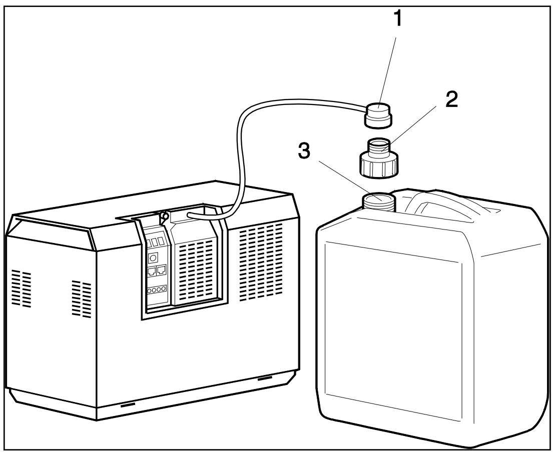
c) Do not remove the child-proof screw cap until the new EFOY fuel cartridge has been inserted into the fuel cartridge holder.

<u>Connecting the M28 Fuel Cartridge Only</u>

The M28 fuel cartridge can only be connected using the M28 adapter.

When connecting an M28 cartridge the M28 Adapter (2) is first screwed onto the Fuel Cartridge (3).

Then the Fuel Cell Connector (1) is screwed into the M28 Adapter (2).



Connecting Other Fuel Cartridges

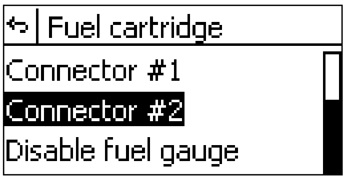
d) Screw the fuel cartridge connector onto the new EFOY fuel cartridge.

e) Press [ok] on the operating panel so that the red warning light and error message are no longer displayed.

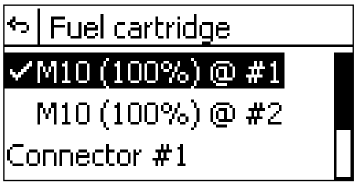
f) Select the installed fuel cartridge on the operating panel.

10.3 Selecting a fuel cartridge

a) When you select the "Fuel cartridge" submenu in the main menu, the display shows the fuel cartridges already enabled and the device connectors.

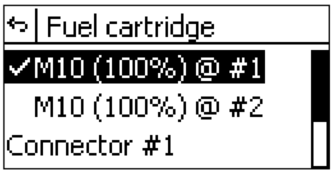


b) The connectors are displayed according to whether you are using an EFOY Pro or EFOY Pro Duo device.



c) If you have not connected a full fuel cartridge, disable the fuel gauge by selecting "Disable fuel gauge" in the menu.

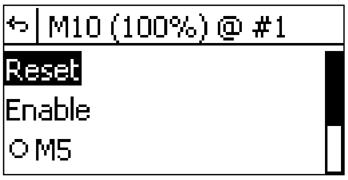
d) Select an active fuel cartridge to edit it directly.



e) Press [ok] to confirm your selection.

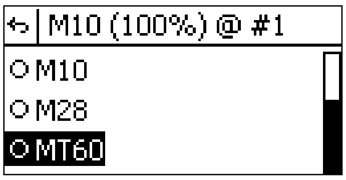
f) You can select the following actions in the fuel cartridge submenu:

- Reset: Resets the counter after the fuel cartridge has been changed.



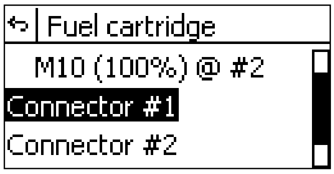
- Enable: Enables the fuel cartridge.

- M5 / M10 / M28 / MT60: Changes the fuel cartridge type for the respective connector.



g) Select a connector to edit the connector and any associated fuel cartridges.

Press [ok] to confirm your selection.

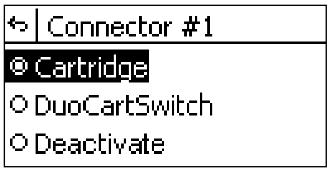


h) You can select the following actions in the connector submenu:

- Cartridge: A single fuel cartridge is to be used at the connector. The associated fuel cartridge is displayed at the highest level of the menu.

- DuoCartSwitch: A DuoCartSwitch is to be used at the connector.

- Deactivate: Disables the connector.



i) Press the menu button once to return to the front screen.

11. DuoCartSwitch DCS 1

The DuoCartSwitch enables you to connect two fuel cartridges to the cartridge connector of one EFOY Pro fuel cell.

The switching valve switches automatically from the fuel cartridge in operation to the reserve fuel cartridge.

This means that the autonomy of the application can be doubled.

Figure 4 - DuoCartSwitch

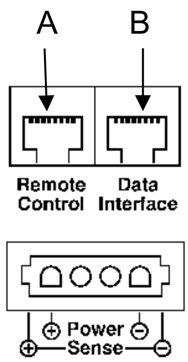
11.1 Connecting the DuoCartSwitch

a) Screw the fuel-cartridge connector of the EFOY Pro on the DuoCartSwitch.

b) Connect one DuoCartSwitch via a Port Doubler to each RJ45-plug of the EFOY Pro:

- A: Remote Control plug.

- B: Data Interface plug.



11.2 If a DuoCartSwitch is added it needs to be activated, for instructions explaining how this is done see Clause 10.3.

12. Fuel cartridge sensor FS1

Figure 5 – FS1 Sensor

a) By default, the EFOY Pro does not monitor the actual fill level of the fuel cartridge.

b) The fuel gauge for the fuel cartridge is just an indicator and calculates the methanol consumption.

c) The FS1 fuel cartridge sensor shall be used to measure the actual fill level.

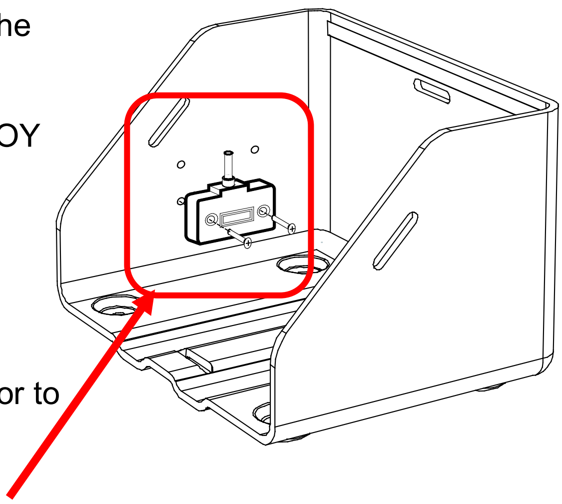
d) The EFOY Pro reports a fuel level error if the cartridge is used up.

e) The optional fuel cartridge sensor FS1 indicates if the fuel level drops below the position of the sensor.

f) This early warning gives the user time to change the cartridge before it is completely empty.

g) The fuel cartridge sensor FS1 may also be used with fuel cartridges that are partly empty.

h) It sends a signal to the EFOY Pro fuel cell when the fill level falls below the sensor.



i) You connect the sensor to the EFOY Pro data interface.

j) The sensor should be combined with a remote monitoring system, e.g. the GSM modem.

k) You fasten the fuel cartridge sensor to the fuel cartridge holder using two screws.

12.2 You can choose from two different heights to mount the FS1.

13. Long term storage

13.1 Store the EFOY Pro fuel cell in a cool place, but at a temperature over +1 °C / +34 °F.

13.2 If the EFOY Pro fuel cell is exposed to temperatures below 0 °C / 32 °F without connected batteries and filled fuel cartridges, it shall be defrosted for approximately 24 hours at room temperature before use.

13.3 After long term storage over 6-month SFC recommends to check the functionality of the EFOY Pro fuel cell before installation.

a) For that purpose, connect the fuel cell to a battery to run a charging cycle.

b) A charging cycle can last several hours.

c) After successfully passing the charging cycle run the transport lock procedure.

d) Press the [menu] and [▼] button on the Operating panel at least 3 seconds and follow the instructions on the display.

Note that liquid can drop out of the exhaust hose tube when running the transport lock procedure.

14. Old devices

Old devices shall be treated as hazardous waste and disposed of in line with NR Environmental Policy.

For advice on returning old devices, please contact the EFOY hotline.

END

Sequence for replacing an WSD Wheel Detector

1. Disconnect the wheel detector cabling in the corresponding disconnection box.

2. Remove the cable securing clips from the WSD cable.

Refer to Figure 1 and Figure 2 for steps 3 to 8.

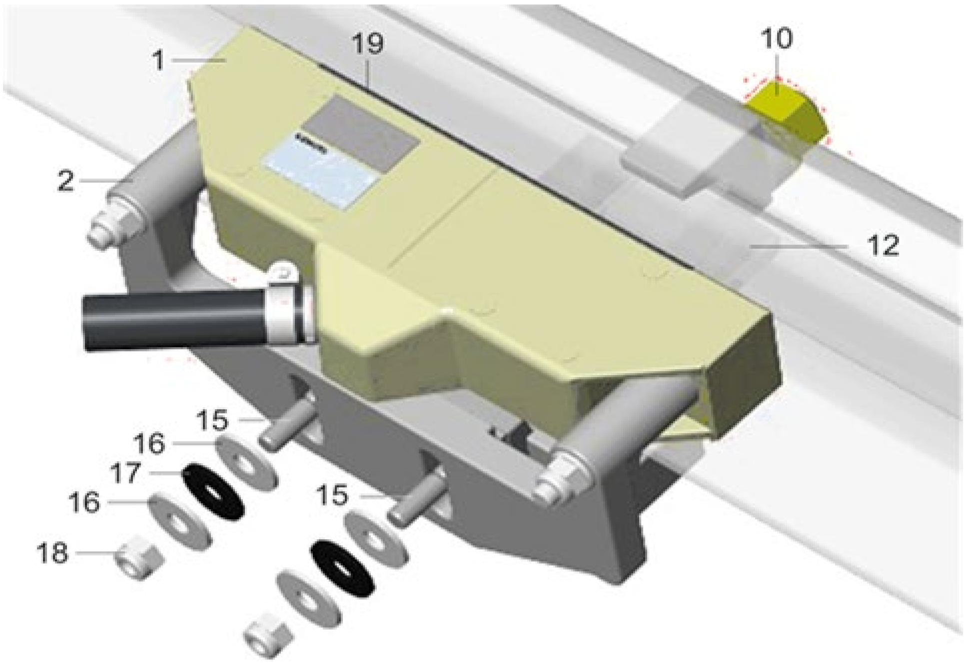


Figure 1 - Parts Identification

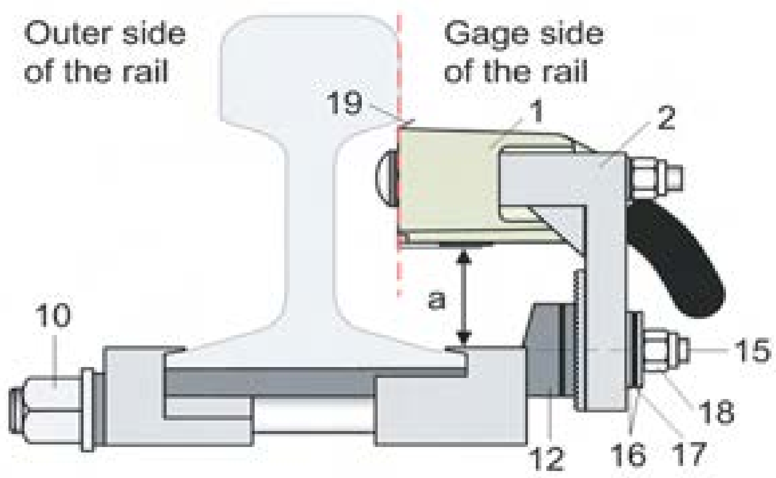

Figure 2 – Mounting Layout

3. Remove the WSD (1) and the height mount (2) from the rail:

   a) Remove two M12 hexagon nuts (18) along with six washers (16 and 17).

   b) Remove the WSD and height mount from the remaining clamp metalwork.

Optionally, if the remaining components of the clamp is to be removed from the rail then:

   c) Remove the M24 collar nut (10) and spring washer (11), see Figure 3.

Figure 3 – M24 Collar Bolt

   d) The clamp metalwork on the non-gauge side could require a tap from a hammer to release the remaining clamp from the bottom of the rail, See Figure 4.

Figure 4 - Removed Clamp Metalwork

4. Remove the WSD (1) from the height mount (2) by removing two M12 hexagon nuts (6), two washers (5), two separators (4) and two bolts (3).

5. Install the replacement WSD to the height mount by refitting the two bolts (3), two separators (4), two washers (5) and two M12 hexagon nuts (6).

6. Tighten the two hexagon nuts (6) using a torque wrench (torque setting of 45 Nm).

   If step 8c has been performed, then:

   a) Fit the bearing assembly (8) on the gauge side of the rail base.

   b) Fit the counterholder (9) on the outer side of the rail base onto the threaded rod of the bearing assembly (8).

   c) Loosely bolt the M24 collar nut (10) onto the threaded rod of the bearing assembly (8) with the spring washer (11) in between.

   d) Insert the bearing plate (12) between the rail base and the bearing assembly (8).

7. Install the height mount (2) with replacement WSD to the rail:

   a) Fit the height mount (2) with the wheel detector (1) onto the studs (15) of the bearing plate (12).

   b) Fit a 36mm washer (16), a damping washer (17), another 36mm washer (16) and an M12 prevailing torque-type hexagon nut (18) onto each stud (15) and tighten them finger-tight.

   c) Move the bearing plate (12) horizontally until the reducing plate (19) of the wheel detector is flush with the side of the rail head (viewed from above).

   d) Tighten the M24 collar nut (10) using a torque wrench (torque setting of 200 Nm). As you do so, make sure the bearing plate does not move horizontally and that the wheel detector is parallel to the rail.

   e) Place the adjustment gauge on the top of the wheel detector. The green sheet-metal strip is located on the top of the adjustment gauge. The inscription "Cal." faces the rail head and is thus not visible.

   f) Loosen the two hexagon nuts (18) again to allow the height mount to be moved vertically with the wheel detector.

   g) Adjust the height mount using the adjustment gauge so that the top of the wheel detector to 45mm (tolerance +0mm/-2mm) below the top of the rail. The mounting height of 45mm below the top of the rail has been reached

When the top of the adjustment gauge is on the same level as the top of the rail. For an accurate measurement place a straight edge across both rail heads.

h) Tighten the two hexagon nuts (18) using a torque wrench (torque setting of 40 Nm).

i) Check that the reducing plate (19) is still flush with the side of the rail head (seen vertically from above). If necessary, loosen the collar nut (10) and readjust the bearing plate.

8. Reconnect the wheel detector wires in the corresponding disconnection box referring to cabling wiring diagrams.

9. Clamp the WSD cable to the securing clips.

END

Includes:	Siemens S21, Ansaldo, Alstom Atlas 200, TASS and Tracklink III Balises
Excludes:	All other Balises and Beacons

SECTION A - SIEMENS S21 PROGRAMMING

Further information can be found in the Siemens S21 A6Z00032385088 (Operating Instructions TPG-Eurobalise).

Programming the Eurobalise Using the TPG.

Warning: Strong electromagnetic fields are generated during the use of the TPG. These might interfere with cardiac pacemakers and might have long-term detrimental effects on health. When the TPG is active keep a minimum distance of 200mm from the unit.

NOTE: *Before starting the programming or verification process, it is recommended to check that the TPG housing battery is fully charged. When the TPG housing red light is on, the battery charge is low.*

1. Hand-held Terminal

1.1 Check the hand-held terminal is switched on.

1.2 To switch on the Hand-held - press the On/Off button in the bottom left corner of the keypad for about three seconds.

1.3 The LED in the top right corner of the keypad flashes green once.

1.4 The display of the Hand-held Terminal is switched on. Either the desktop or the last page used is displayed.

If the Hand-held Terminal has no system time or an incorrect system time due to a discharged battery, set the correct date and the time of day.

This can be done through the start menu, select settings followed by Control Panel.

Further details are contained within the manual.

Figure 1 – Hand-held Terminal

1.5 Setting the date and time is important because the file names contain the system time.

1.6 It is only by entering a system time that various files can be distinguished.

To switch off the device press the On/Off button in the bottom left corner of the keypad.

NOTE: *switching off the Hand-Held Terminal during Eurobalise programming leads to incorrectly programmed Eurobalises.*

Do NOT switch off the hand-held terminal while any function is being executed.

When the Hand-held Terminal is switched on again, the TPG continues the operating step where it left off.

If the Hand-held Terminal is switched off during the execution of a function, the TPG attempts to resume the functional sequence.

For safety reasons, however, the TPG then aborts the functional sequence and issues an error message.

The Hand-held Terminal is now switched off.

NOTE: *The Hand-held Terminal features a touch screen which can be used to call up most of the functions. The touch screen can be operated either by finger (or fingernail) or with the supplied stylus. The stylus is found in a slot above the touch screen.*

Figure 2 – Stylus Location

2. Transferring the telegram to the handheld

NOTE: *This process requires an NR laptop or desktop PC which has a DVD drive and "windows Device Mobile Centre" software installed.*

2.1 Insert the CD-ROM with the correct telegram into the PC or Laptop.

2.2 Connect the hand-held terminal to the PC Dock using the USB cable and wait for Windows Mobile Connect to launch.

2.3 Once windows mobile has started, click [connect without setting up your device] hover the mouse over [file management] and select the drop-down menu [browse contents of your device].

Figure 3 – Hand-held Terminal

2.4 The computer drives are now shown, select [Flash Disk] select a folder or make a new one in preparation of file transfer from the DVD.

2.5 Drag and drop the telegram file from the DVD into the folder on the Flash Drive, once completed, the hand-held terminal is ready to programme a balise.

NOTE: *the MD4 Checksum paperwork is stored in the same file as the telegram, this is needed later.*

3. TPG Base Unit on the Eurobalise

3.1 Place the TPG base unit on the Eurobalise and align the TPG base unit using the housing feet see Figure 4.

Figure 4 - TPG Base Unit Positioned on Eurobalise.

or

3.2 Turn the TPG base unit upside down and lay it on its upper side.

Figure 5 - Eurobalise Positioned on TPG Base Unit

3.3 Position the Eurobalise with the upper side (Siemens logo) facing downward on the TPG base unit and align the Eurobalise using the housing feet.

4. TPG Start-up (Battery Operation)

4.1 Press the “On” button on the TPG base unit.

Figure 6 – Power Switch and Indications

The TPG base unit switches on, and the green “Power” LED is illuminated.

5. TPG Start-up (External Power)

5.1 Use the “External power” socket to connect the TPG base unit with a 110V or 230V at 50 Hz or 60 Hz external power source.

5.2 The TPG base unit switches on, and the green “Power” LED is illuminated.

6. Programming

6.1 In the functional area EUROBALISE, select the PROGRAM command, a selection dialog opens.

6.2 Select the telegram file provided for the Eurobalise in the selection dialog, the programming runs automatically. This is indicated by the progress bar.

6.3 When the operation has ended, one of the following messages is shown:

a) MD4: The 16 hexadecimal characters.

The Eurobalise has been correctly programmed and the newly programmed data has been read.

Check the displayed 16 Hexadecimal characters of the MD4 checksum document from the relevant folder on the CD-ROM.

If the checksum is incorrect repeat the programming operation. A maximum of three attempts are allowed.

b) Signal Level too low

The Eurobalise reply level is too weak, the programming is aborted.

Clean the Eurobalise and repeat the programming.

c) Wrong Eurobalise Identifier or not a Siemens Balise.

d) The Eurobalise type cannot be programmed or the unit is faulty.

6.4 Complete the Certificate of Conformity (CoC) when the Balise has been correctly programmed. Place the CoC in a plastic sleeve and attach to the Balise.

7. Checking the Programming

7.1 Make sure that the Eurobalise is correctly placed and that the TPG is switched on.

7.2 In the BALISE functional area, select the TLG COMPARISON command, a selection dialog opens.

7.3 Select the telegram file on the hand-held for the comparison, the TPG reads the Eurobalise telegram and compares it with the selected telegram file.

This is indicated by the progress bar. When the operation has ended, one of the following messages are shown:

a) Compared Telegrams are Identical:

The Eurobalise telegram corresponds to the telegram file, programming is successful.

b) Compared telegrams are NOT identical:

The Eurobalise telegram fails to correspond to the telegram file, the wrong telegram might have been programmed into the Balise or the system has failed.

c) Signal level too low:

Clean the Eurobalise and repeat the process.

8. Verification

Determination of Signal Level

8.1 The TPG should be correctly placed and switched on.

8.2 In the BALISE functional area, select the SIGNAL LEVEL command.

NOTE: *the TPG measures the level of the reply signal from the Eurobalise. The status of the measuring operation is shown by a progress bar on the display.*

8.3 On completion, one of the following messages is displayed:

a) Signal Level OK.

b) Signal Level too Low.

Clean the Eurobalise and repeat the measurement.

9. MD4 Checksum

9.1 The TPG should be properly connected and switched on.

9.2 In the Eurobalise functional area, select the DISPLAY MD4 command, the TPG reads out the Eurobalise telegram and calculates the MD4 checksum.

This is indicated by the progress bar. When the operation has ended, one of the following messages are shown:

a) MD4: the 16 hexadecimal characters, check the displayed characters of the MD4 checksum against the checksum on the programming and verification form from the DVD folder.

If correct – confirmation of the correctly programmed telegram, complete the Certificate of Conformity (CoC).

If incorrect – Check the function of the hand-held against a known working Balise, if OK fail the programming.

b) Signal level too low, clean the Eurobalise and repeat the process.

SECTION B - ANSALDO BALISE PROGRAMMING

Further information can be found in the Ansaldo CL-OM-00323 (Manual for Balise Programming).

NOTE: *prior to use the battery level of the VPT should be confirmed, this is achieved by setting the external switch to [programming] then to [verification] and check the corresponding LED turns on. There are 3 LEDs to show the charge status 100%, 66% and 33%. If the indication 33% or the discharge LED is on recharge the VPT as soon as possible.*

Warning: Do not use the equipment to program or check Balise's while the battery is on charge.

Check the battery status of the Pocket PC, the charge percentage is visible in [Start]-[Settings]-[System] -[Power].

1. Loading Telegrams into The Pocket PC

NOTE: *A PC, on which the files are already installed is to be used for programming and/or checking the Balise telegrams.*

The telegram files have the extension TGO; the name of the file should correspond with the Balise identifier.

The ActiveSync software for the handheld computer should already be installed on the same PC.

1.1 Connect a null modem cable, to the serial port on the PC and to the serial port of the Pocket PC.

1.2 Clip on the protector of the Pocket PC on the connector cable 2. Use the cable equipped with RS232 connectors to make the serial link between the Pocket PC and the PC.

1.3 Communication between the Pocket PC and the PC is established automatically.

1.4 On the PC, when the "Definition of a partnership" window appears, select [NO] at the request "Do you wish to establish a partnership?" on the PC, then select [Next].

1.5 Once connected, the window shown in Figure 7 appears:

Figure 7 – PC Connection Window

1.6 In the PC window, open the Pocket PC folder, to which the file(s) is transferred, by clicking on the “Explorer” icon.

1.7 On the PC, select the files (or the whole folder) to be transferred and insert them into the destination folder on the Pocket PC.

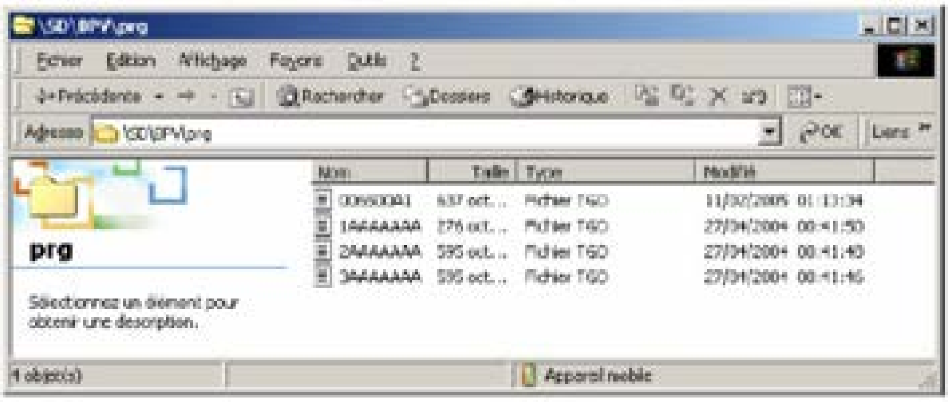

Figure 8 – File Transfer

1.8 Check, in the Pocket PC folder, that the necessary files have been downloaded.

1.9 Close the ActiveSync application on both computers and disconnect the Pocket PC from the PC (disconnection of the cable closes the ActiveSync application automatically).

CHECK CORRECT WORKING OF THE VPT BY USING A “SPECIMEN” BALISE.

1.10 Check the VPT operation against a known working Balise for correct telegram reading.

1.11 Switch the Pocket PC on by pressing the key (top right) and the display should appear.

Figure 9 – Location of On/Off Switch

NOTE: *It is not necessary to restart the BPV application for each balise. If there is no image, recharge the batteries located in the Pocket PC.*

1.12 Run the application by clicking on [START]-[Programs]-[File Explorer]-[SD]-[BPV] then on “bpv”.

Figure 10 –Application Sequence

NOTE: *The Balise Part Number, Serial Number and Version Number are necessary. This is indicated by a sticker on the balise.*

Figure 11 – Balise Details

1.13 Check the Balise part number corresponds with the part number on the screen. If they do not match, click on the X to exit the program, and modify the part number in the file pn.txt.

Figure 12 – Balise Part Number

1.14 Enter the balise serial number (S/N, 7 to 9 characters) and then click okay.

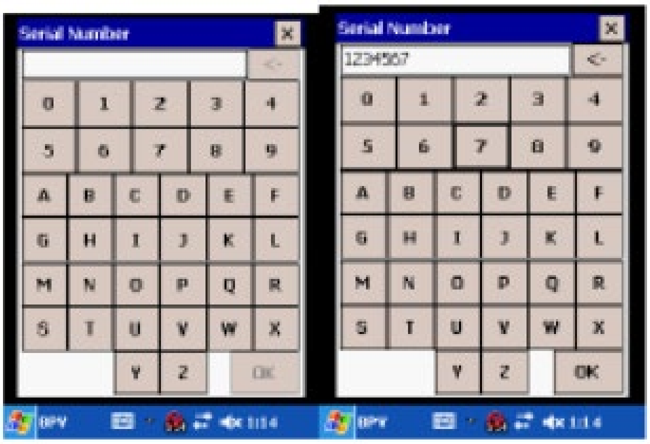

Figure 13 – Entering the Serial Number

1.15 Enter the balise Version Number and then click okay.

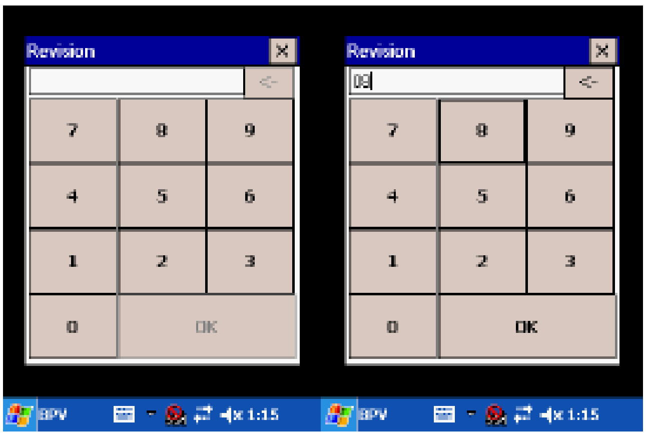

Figure 14 - Entering Version Number

1.16 Enter the 8-digit ID-BOA comprised of the N_BG+A+N_PIG i.e. BG123456A0 and then click okay.

Figure 15 - 8-digit ID-BOA

1.17 When the data input phase is finished, the display shows the version of the application software installed in the Pocket PC, as well as the names of the files < >.TGO which are in the Pocket PC in sub-folders PRG. Verify that the correct .TGO file is available for the balise being programmed.

2. Functions available via the menu

2.1 When the phase of inputting data relating to the Balise has finished, the Pocket PC screen displays the following window:

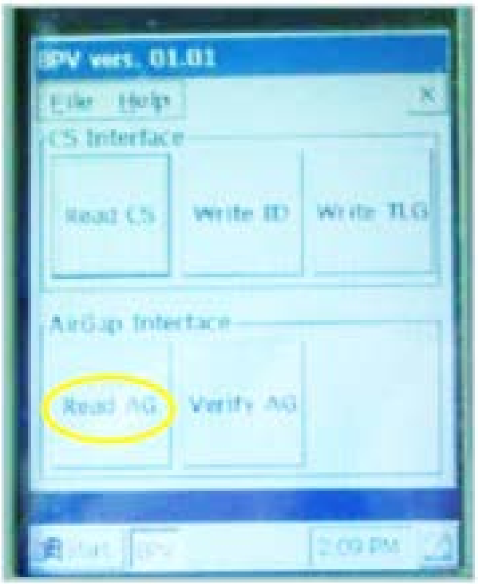

Figure 16 – Inputting complete Screen

2.2 To check the Balise across the air-gap, it is necessary to position the rack above the Balise, in direct contact with it, as close to the centre as possible.

Figure 17 – Checking the Air Gap

2.3 In the case where the selected function ends incorrectly, (with a message "ERROR [rack inactive / defective]"), before trying again, first set the external switch to the centre position.

3. Activation of Menu Functions

Reading a Telegram (C5)

3.1 Set the switch on the inside of the rack to "ON", and the external switch to "PROGRAMMING" [P].

3.2 This operation (which can be selected by clicking on [Read C5] in interface C5 in the Main Menu (Figure 16) allows data stored in the Balise to be read.

3.3 It is necessary to wait about 10 seconds before the data stored in the Balise is displayed on the screen.

3.4 The following data appears in the first line (in hex):

a) The 16 bits hard-wired in the Balise (E89C).

b) The Balise ID the telegram shown in 256 Hex characters.

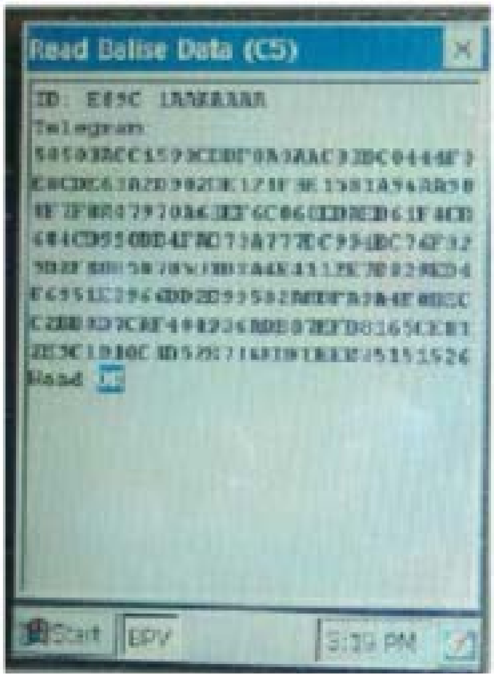

Figure 18 – Balise Data

NOTE: *During this operation, the data stored in the Balise is read but no check is made on them. If the data link is disconnected, or if there is no message in the balise, it reads as all 'F'.*

3.5 A read OK message states that the ID_BOA and the telegram can be read.

3.6 A Read NOK message states that either the ID_BOA or the telegram cannot be read.

<u>Writing ID BOA (C5)</u>

3.7 Set the switch on the inside of the rack to “ON”, and the external switch to “PROGRAMMING” [P].

3.8 Select [Write ID] to write the Balise ID.

NOTE: *writing the Balise ID is subject to entering the correct login (User Identification) and password, just after clicking on [ID boa].*

Figure 19 – Entering the Balise ID

3.9 A successful write is shown by an on-screen message, for example: “Write AAAAAAA2... OK”.

<u>Writing A Telegram to A Balise (C5)</u>

3.10 Set the switch on the inside of the rack to “ON”, and the external switch to “PROGRAMMING” [P].

3.11 Select [Write Telegram] to write the Telegram.

NOTE: *this operation is only possible if the Balise ID of the Balise corresponds to the telegram that you want to write.*

3.12 After the balise ID is checked the telegram to be written is displayed on the Pocket PC. Select [confirm] to write the telegram if correct or [cancel] if the wrong telegram is displayed.

NOTE: *when the write phase has ended, the data stored in the Balise is read back automatically and then displayed; confirmation (OK) of the result of the comparison between the telegram to be stored and the telegram actually stored then appears (see Figure 20).*

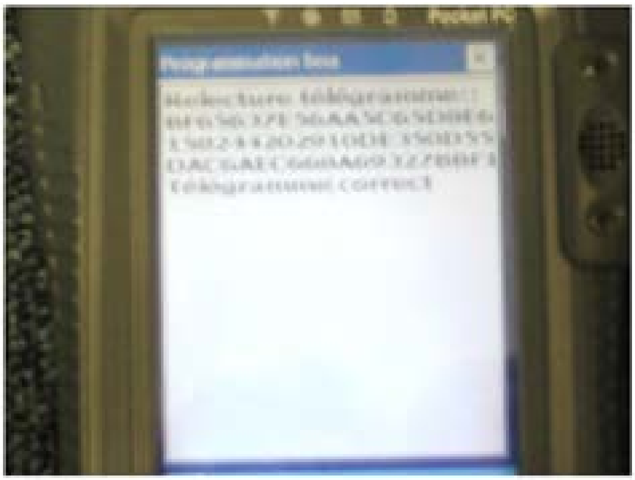

Figure 20 - Telegram

Reading A Telegram (Air-Gap)

3.13 This operation can be selected by clicking on [Read AG] in the AIR-GAP interface in the Main Menu (Figure 16).

3.14 Position the rack above the Balise, in direct contact, taking care to maintain a distance of at least 1 metre from any metallic object likely to affect the performance of the radiating elements in the rack and in the Balise.

3.15 Connect the Pocket PC to the rack; then set the switch inside the rack to the “ON” position and the external switch to “VERIFICATION”.

3.16 Select [Read AG] in the AIR-GAP interface in the Main Menu of the Pocket PC which activates the Balise and reading of the telegram.

Figure 21 – Read AG

<u>Verification</u>

NOTE: *Position the rack above the Balise, in direct contact, taking care to maintain a distance of at least 1 metre from any metallic object likely to affect the performance of the radiating elements in the rack and in the Balise.*

3.17 Set the switch inside the rack to “ON” and the external switch to “VERIFICATION”.

3.18 Select [Verify AG] in the AIR-GAP interface in the Main Menu (Figure 16), the telegram sent by the Balise is read, but is also compared with the telegram contained in a pre-loaded file in the Pocket PC.

3.19 Choose fixed Balise [PRG] which activates the Balise and reading of the transmitted telegram.

3.20 Select [OK], the corresponding “User bit” are displayed and the result of the comparison appear in the last line (see Figure 22).

Figure 22 – Balise Testing Air Gap

SECTION C - ALSTOM ATLAS 200 EUROBALISE PROGRAMMING AND VERIFICATION

Warning: Strong electromagnetic fields are generated during the use of the BEPT, these might interfere with cardiac pacemakers and should not be used by anyone with a pacemaker fitted.

Further information can be found in the Alstom Atlas 200 ALS/UK/ATLAS200-SYS-MAN-00005 (BEPT User Manual).

1. Connecting the BEPT to the Handheld PC

1.1 Verify that no USB media is connected to the BEPT before the power up sequence has finished, if fitted the BEPT attempts a factory reset.

1.2 Switch-on the BEPT Core, ON/OFF indicator is lit.

1.3 After the booting delay, PC Ready indicator is lit.

1.4 BEPT Core is now ready to be used.

1.5 Insert the USB stick to the BEPT, with the relevant telegram files to be programmed.

NOTE: *Do not insert the USB stick before the BEPT has finished its start-up process, this causes the BEPT to try and enter a recovery mode and the BEPT cannot boot.*

1.6 Place the BEPT on the top of the Balise locating the feet of the test set in the recess on the Balise.

1.7 Start the handheld PC and wait for it to boot up.

1.8 Use the WiFi connection tool to connect the handheld to the BEPT using the SSID and Password.

NOTE: *The WiFi code matches the serial number on the BEPT.*

1.9 Once connected to the WiFi open internet explorer 11 and navigate to the following address http://192.168.10.1/BEPT.

1.10 The handheld now shows a login window.

2. Programming

2.1 Select the [programming] account and login using your credentials.

2.2 On the left-hand menu select [Write Eurotelegram] and the following window opens:

Figure 23 – Write telegram screen

2.3 Confirm the interface drop down menu is set to [Compact] then left click [Browse] and a pop-up window appears.

2.4 Scroll to the bottom of the left-hand window to select the last drive letter, usually the ‘F’ drive. Once selected the telegrams on the USB stick are available in the right-hand window.

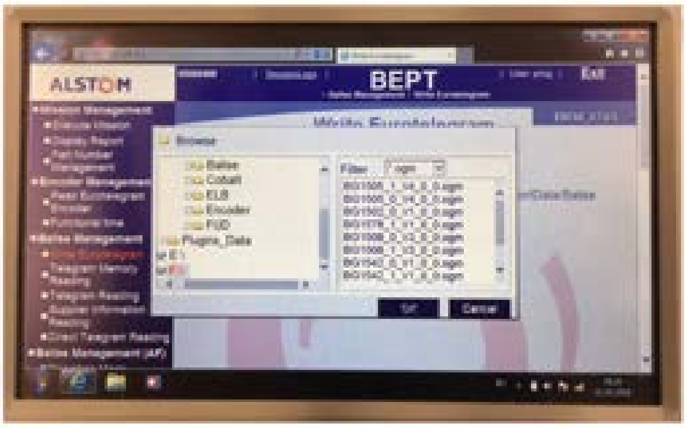

Figure 24 – Telegram selection

2.5 Scroll the right-hand window until you see the telegram file you are looking for, select the file with the touch screen pen and click [ok].

2.6 The pop-up window closes, and the handheld displays the telegram file that is to be programmed into the Balise.

NOTE: *Confirm the telegram being loaded is the correct telegram for the Balise being programmed and it matches the certificate of conformity.*

2.7 Confirm the check tick box is selected and click [Write] the telegram is written to the balise.

Two possible results are returned:

a) ✓ Eurotelegram written successfully.

b) × An error has occurred.

Figure 24 – Telegram written successfully

2.8 Providing the write was successful you can now check the telegram by selecting [telegram reading] in the left-hand menu.

NOTE: *Do not select Telegram Memory reading as this does not show the signal strength meter.*

Figure 25 - Telegram reading

2.9 Confirm the [Check Telegram] tick box is NOT selected and click [Read], it takes approx. 10 seconds to read the telegram in the Balise. Once read the following window appears (Figure 26).

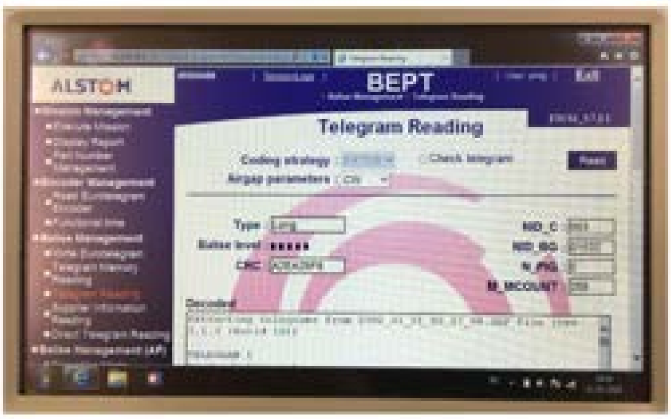

Figure 26 – Telegram check

2.10 In this window you can check the correct telegram has been loaded by checking the following:

a) NID_C – Country Code (UK is 003).

b) NID_BG – The Balise Group Number.

c) N_PIG – Position in Group.

d) M_MCOUNT – Should show 255 which is the packet number for End of Telegram.

e) Balise Level - minimum 4 out of 5 bars.

f) CRC - checksum code.

2.11 Complete all programming paperwork and complete the programming section of the certificate of conformity which shall be attached to the Balise.

3. Verification.

3.1 Select [verification] account and login using your credentials.

3.2 On the left-hand menu select [Telegram Reading].

NOTE: *Do not select Telegram Memory reading as this does not show the signal strength meter.*

Figure 27 – Telegram reading

3.3 Confirm the [Check Telegram] tick box is NOT selected and click [Read], it takes approx. 10 seconds to read the telegram in the Balise. Once read the following window appears (Figure 28).

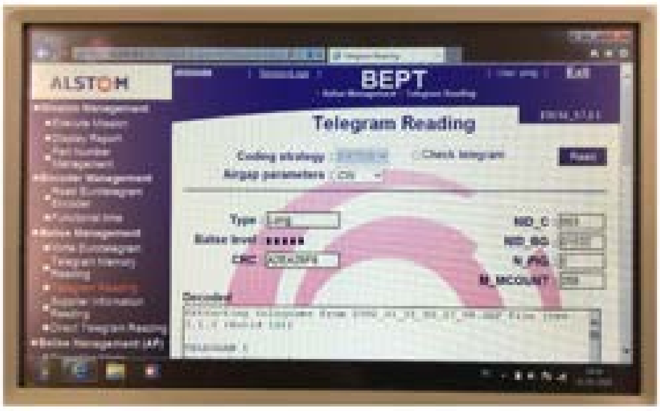

Figure 28 – Telegram check

3.4 In this window you can confirm the correct telegram has been loaded by checking the following against the programming paperwork and certificate of conformity entries:

a) NID_C – Country Code (UK is 003).

b) NID_BG – The Balise Group Number.

c) N_PIG – Position in Group.

d) M_MCOUNT – Should show 255 which is the packet number for End of Telegram.

e) Balise Level - minimum 4 out of 5 bars.

f) CRC - checksum code.

3.5 Complete all programming paperwork and complete the verification section of the certificate of conformity which shall be attached to the Balise.

4. Erasing

NOTE: *An Alstom Atlas 200 Balise cannot be over written with a new Telegram, in-order to change the telegram it needs to be erased first.*

4.1 Select [Eraser] account and login using your credentials.

4.2 On the left-hand menu select [Write Telegram].

Figure 29 - Write Telegram

4.3 Confirm the interface drop down menu is set to [Compact] and click [Browse].

4.4 The Balise erase telegram is pre-loaded to the BEPT and is shown in the right-hand side of the pop-up window.

Figure 30 – Erase telegram

4.5 Select the [Reset_Balise_ID.tgm] file and then select [OK].

4.6 Once the pop-up window has closed select [Write] two possible results are returned:

a) ✓ Eurotelegram written successfully.

b) × An error has occurred.

4.7 Providing the write was successful the Balise is now ready to receive a new telegram.

SECTION D – TASS PROGRAMMING

Further information can be found in the TASS Balise C80056-SPEC-SYS-00166-07 (BEPT User Manual).

Warning: Only the supplied stylus is to be used on the display, Pens, Nails Paper Clips etc can damage the surface of the display and should not be used.

NOTE: *Before closing the handheld case, disconnect the battery charger. The display battery charger lead may be left connected if the display is inside the case, but the case cannot be closed or locked.*

NOTE: *The power supply cable and balise programming cable should only be connected in the depot environment and should be disconnected and stored before proceeding trackside.*

1. Powering Up the Toughbook PC and Display

1.1 Open the case, check the floppy disk drive (FDD), mounted in the BEPT case lid, to verify that no floppy disk is present.

1.2 Press the power button on the Toughbook PC and hold until a tone is heard. The Power status LED should be lit solidly, and the Hard Disk Access LED should light intermittently.

1.3 Once the “Display Ready” LED on the Toughbook PC illuminates, remove the stylus from the rear of the display next to the battery charger socket and use it to press and hold the monitor power button until the Power Status LED illuminates. The display should be present on the monitor within 5 seconds, once present, the BEPT is now ready for data input.

1.4 Connect the balise programming cable to the BEPT and the balise via the socket on the outside of the BEPT and the Balise connection socket.

Caution: Before proceeding with the BEPT operation verify the locking (pull to unlock) toggle switch is in the BEPT position.

To disconnect, use the key to unscrew the plug from the socket.

1.5 Position the BEPT on the Balise longitudinally with the handles of the carry handle at right angles to the balise X Axis.

1.6 Double tap on the desktop shortcut using the stylus.

1.7 Or in Windows Explorer, select C:\ProgramFiles\ATIS_TASS_BEPT\BeptTass.exe.

1.8 Enter your user name into the text field on the display, this unlocks the functions of the BEPT.

NOTE: *The entered user name remains valid for all operations until the TASS BEPT application is shut down.*

2. Programming

NOTE: *Balise programming should only be performed in the office/depot environment. The handheld case is to remain open throughout the operation.*

2.1 Select the DEPOT button, The DEPOT screen with four buttons is displayed.

2.2 Connect the balise programming cable between the case socket and the balise.

2.3 Select the PROGRAM BALISE button.

2.4 Inter-connection checks are performed; PC to BEPT reader connection and BEPT to balise connection present and correct. STATUS = “Connection Check”.

If the PC to BEPT reader connection is faulty:

- RESULT = “FAILED, PC to BEPT connection faulty”, and the programming operation is halted. Refer to section 4 for user action.

If the connection between the BEPT and the balise is faulty:

- RESULT = “FAILED, BEPT to Balise connection faulty”, and the programming operation is halted. Refer to section 4 for user action.

If the two connections are correct:

- RESULT = “Connection OK”.

2.5 Select the telegram to be programmed either from an inserted Floppy Disc or if the telegram is in the local memory of the BEPT carry out this process:

a) When prompted to insert a Floppy Disk click [Cancel].

b) A file browser window pops up which defaults to the desktop, browse the folders on the PC to the stored location and select the telegram to be programmed.

NOTE: *Selection of the file browser window Cancel button closes the file browser window, stop the current process and re-enable all buttons, RESULT = "Cancellation of TGM file selection".*

2.6 The selected telegram file is submitted to coding strategy check, STATUS = "Telegram Coding Check".

If the coding strategy check fails:

- RESULT = "FAILED, telegram file corrupt" and the programming operation is halted.

If the coding strategy check is successful,

- RESULT = "Telegram file OK".

NOTE: *If the coding strategy check is passed, the STATUS and RESULT fields might change too quickly to notice.*

The selected telegram data is written to the balise via the cable and balise connector, STATUS = "Writing telegram".

If the write operation is unsuccessful:

- RESULT = "FAILED, write operation unsuccessful" and the programming operation is halted. Refer to section 4 for user action.

If the write operation is successful:

- RESULT = "Write operation OK".

NOTE: *If the write operation is successful, the STATUS and RESULT fields might change too quickly to notice.*

2.7 The telegram data is read from the balise via the cable and balise connector, STATUS = "Reading telegram".

If the read operation is unsuccessful i.e. no telegram is read from the balise:

- RESULT = "FAILED, read operation unsuccessful" and the programming operation is halted.

If the read operation is successful,

- RESULT = “Read operation OK”.

NOTE: *If the read operation is successful, the STATUS and RESULT fields might change too quickly to notice.*

2.8 The read telegram data is compared with the selected telegram file data, STATUS = “Comparing telegrams”.

If the comparison is unsuccessful i.e. the read data and the selected data are not identical:

- RESULT = “FAILED, Write telegram not same as Read telegram” and the programming operation is halted.

If the comparison is successful i.e. the read data and the selected data are identical:

- RESULT = “Write telegram same as read telegram”.

NOTE: *If the comparison operation is successful, the STATUS and RESULT fields might change too quickly to notice.*

2.9 The user is prompted to disconnect the balise programming cable, STATUS = “Disconnect programming cable”. The disconnection can either be at the BEPT case socket, or at the balise connector. Check that the handheld case is located on top of the balise.

2.10 When the handheld case is correctly located on the balise, and the cable is disconnected, the user selects the OK button.

2.11 If the BEPT to balise connection is still detected as being present, the user is presented with the disconnection prompt again, up to a maximum of three times.

- RESULT = “FAILED, cable not disconnected”, and the programming operation is halted.

2.12 If the BEPT to balise connection is detected as being removed, the BEPT telepowers the balise. The balise transmits the telegram data currently held in memory, and the BEPT receives and logs this data. STATUS = “Reading via airgap”.

If no telegram data is received:

- RESULT = “FAILED, no telegram received via airgap” and the programming operation is halted.

If telegram data is received:

- RESULT = “Read operation OK”.

NOTE: *If the airgap read operation is successful, the STATUS and RESULT fields might change too quickly to notice.*

2.13 The received telegram data is compared with the selected telegram file data, STATUS = “Comparing telegrams”.

If the comparison is unsuccessful i.e. the received data and the selected data are not identical:

- RESULT = “FAILED, Read telegram not same as selected” and the programming operation is halted.

If the comparison is successful i.e. the received data and the selected data are identical:

- RESULT = “PASSED, balise programming successful”. This result confirms that the selected telegram data has been successfully programmed into the balise, and the balise is functional.

NOTE: *The user is presented with a popup requesting whether the selected telegram file is to be deleted. If YES is selected, the telegram file is deleted from where it was selected, if NO, it is not. Selection of either button ends the programming operation, and all buttons in the DEPOT screen are enabled.*

3. Reading a balise

3.1 Confirm that the programming cable is disconnected.

3.2 Check that the BEPT case is located on top of the balise.

3.3 After power up, start up and the entry of a user name, select the DEPOT button. The DEPOT screen with four buttons is displayed.

3.4 Select the READ BALISE button.

3.5 Inter-connection checks are performed; PC to BEPT reader connection present and correct, BEPT to balise connection NOT present. STATUS = “Connection Check”:

If the PC to BEPT reader connection is faulty:

- RESULT = “FAILED, PC to BEPT connection faulty”, and the read operation is halted.

If the connection between the BEPT and the balise is present:

- RESULT = “FAILED, BEPT to Balise connection faulty”, and the read operation is halted.

If the two connections are correct:

- RESULT = “Connection OK”.

3.6 A popup is displayed for the user to select whether a telegram comparison is required. Select YES if comparison is required, NO if not.

If Yes is selected choose the telegram to be compared either from an inserted Floppy Disc, or if the telegram is in the local memory of the BEPT carry out this process:

a) When prompted to insert a Floppy Disk click [Cancel].

b) A file browser window pops up which defaults to the desktop, browse the folders on the PC to the stored location and select the telegram to be compared.

NOTE: *Selection of the file browser window Cancel button closes the file browser window, stop the current process and re-enable all buttons, RESULT = “Cancellation of TGM file selection”.*

3.7 The selected telegram file is submitted to a coding strategy check, STATUS = “Telegram Coding Check”.

If the coding strategy check fails:

- RESULT = “FAILED, telegram file corrupt” and the read operation is halted.

If the coding strategy check is passed,

- RESULT = “Telegram file OK”.

NOTE: *If the coding strategy check is passed, the STATUS and RESULT fields might change too quickly to notice.*

3.8 The user is prompted to enter the ID number of the balise being read, the OK button is enabled only if an ID has been entered in the Balise ID text field. No more than 14 characters can be entered.

Clicking on Cancel removes the popup, stop the current process and re-enable all buttons, RESULT = “Cancellation of Balise ID selection”.

3.9 The BEPT telepowers the balise. The balise transmits the telegram data currently held in memory, and the BEPT receives and logs this data. STATUS = "Reading via airgap".

If no telegram data is received:

- RESULT = "FAILED, no telegram received via airgap" and the read operation is halted.

If telegram data is received:

- RESULT = "Read operation OK".

NOTE: *If the airgap read operation is successful, the STATUS and RESULT fields might change too quickly to notice.*

3.10 The received telegram data is compared with the selected telegram file data, STATUS = "Comparing telegrams".

If the comparison is unsuccessful i.e. the received data and the selected data are not identical:

- RESULT = "FAILED, Read telegram not same as selected" and the read operation is halted.

If the comparison is successful i.e. the received data and the selected data is identical:

- RESULT = "PASSED, balise read successful". This result confirms that the selected telegram data is present and not corrupt in the balise, and the balise is functional.

3.11 The user is presented with a popup requesting whether the selected telegram file is to be deleted. If YES is selected, the telegram file is deleted from where it was selected, if NO, it is not. Selection of either button ends the programming operation, and all buttons in the DEPOT screen are enabled.

If NO selected:

a) The user is prompted to enter the ID number of the balise being read, see figure 15. The OK button is enabled only if an ID has been entered in the Balise ID text field. No more than 14 characters can be entered.

b) Clicking on Cancel removes the popup, stop the current process and re-enable all buttons, RESULT = "Cancellation of Balise ID selection".

3.12 The BEPT telepowers the balise. The balise transmits the telegram data currently held in memory, and the BEPT receives and logs this data. STATUS = “Reading via airgap”.

If no telegram data is received:

- RESULT = “FAILED, no telegram received via airgap” and the read operation is halted.

If telegram data is received:

- RESULT = “Read operation OK”.

NOTE: *If the airgap read operation is successful, the STATUS and RESULT fields might change too quickly to notice.*

3.13 The received telegram data is submitted to a coding strategy check, STATUS = “Telegram Coding Check”.

If the coding strategy check fails:

- RESULT = “FAILED, telegram file corrupt” and the read operation is halted.

If the coding strategy check is passed:

- RESULT = “PASSED, balise read successful”. This result confirms that a non-corrupt telegram is stored within the balise, and the balise is functional.

4. Commissioning a Balise (Trackside)

NOTE: *Before proceeding trackside, verify that both the power supply cable and the balise programming cable have been disconnected from the unit, and that the handheld case is closed.*

CAUTION: When operating trackside, balise programming or reading should only be initiated when the BEPT is in place, on the balise, which is properly fixed in the four foot.

4.1 Power up the PC and monitor as per section 1-8 inclusive.

4.2 Check that the programming cable is disconnected.

4.3 Close and seal the case, ensuring that the monitor is not still in the case.

4.4 Check that the BEPT case is located on top of the balise.

4.5 After start up and the entry of a user name, select the TRACKSIDE button.

4.6 Select the COMMISSION button.

4.7 Inter-connection checks are performed; PC to BEPT reader connection present and correct, BEPT to balise connection NOT present. STATUS = “Connection Check”:

If the PC to BEPT reader connection is faulty:

- RESULT = “FAILED, PC to BEPT connection faulty”, and the commission operation is halted.

If the connection between the BEPT and the balise is present:

- RESULT = “FAILED, BEPT to Balise cable connected”, and the commission operation is halted.

If the two connections are correct:

- RESULT = “Connection OK”

4.8 A file browser window defaulting to the c:\Program Files\ATIS_TASS_BEPT\Telegram.

4.9 The file directory is be displayed, select the telegram to be programmed either from an inserted Floppy Disc or if the telegram is in the local memory of the BEPT carry out this process:

a) When prompted to insert a Floppy Disk click [Cancel].

b) A file browser window pops up which defaults to the desktop, browse the folders on the PC to the stored location and select the telegram to be programmed.

NOTE: *Selection of the file browser window Cancel button closes the file browser window, stop the current process and re-enable all buttons, RESULT = “Cancellation of TGM file selection”.*

4.10 Clicking on the file browser window Cancel button closes the file browser window, stop the current process and re-enable all buttons, RESULT = “Cancellation of TGM file selection”.

4.11 The selected telegram file is submitted to a coding strategy check, STATUS = “Telegram Coding Check”.

If the coding strategy check fails:

- RESULT = "FAILED, telegram file corrupt" and the commission operation is halted.

If the coding strategy check is passed:

- RESULT = "Telegram file OK".

NOTE: *If the coding strategy check is passed, the STATUS and RESULT fields might change too quickly to notice.*

4.12 The user is prompted to enter the ID number of the balise being commissioned, the OK button is enabled only if an ID has been entered in the Balise ID text field. No more than 14 characters can be entered.

4.13 Clicking on Cancel removes the popup, stop the current process and re-enable all buttons, RESULT = "Cancellation of Balise ID selection".

4.14 The BEPT telepowers the balise. The balise transmits the telegram data currently held in memory, and the BEPT receives and logs this data. STATUS = "Reading via airgap".

If no telegram data is received:

- RESULT = "FAILED, no telegram received via airgap" and the commission operation is halted.

If telegram data is received:

- RESULT = "Read operation OK".

NOTE: *If the airgap read operation is successful, the STATUS and RESULT fields might change too quickly to notice.*

4.15 The received telegram data is compared with the selected telegram file data, STATUS = "Comparing telegrams".

If the comparison is unsuccessful i.e. the received data and the selected data are not identical,

- RESULT = "FAILED, Read telegram not same as selected" and the commission operation is halted.

If the comparison is successful i.e. the received data and the selected data are Identical:

- RESULT = "PASSED, balise read successful". This result confirms that the selected telegram data is present and not corrupt in the balise, and the balise is functional.

The user is presented with a popup requesting whether the selected telegram file is to be deleted. If YES is selected, the telegram file is deleted from where it was selected, if NO, it is not.

Selection of either button ends the programming operation, and all buttons in the TRACKSIDE screen are enabled.

5. Reading a Balise (trackside)

NOTE: *Before proceeding trackside, verify that both the power supply cable and the balise programming cable have been disconnected from the unit and that the handheld case is closed.*

CAUTION: When operating trackside, balise programming or reading should only be initiated when the BEPT is in place, on the balise, which is properly fixed in the four foot.

5.1 Power up the PC and monitor.

5.2 Check that the programming cable is disconnected.

5.3 Close and seal the case, ensuring that the monitor is not still in the case.

5.4 Check that the BEPT case is located on top of the balise.

5.5 After start up and the entry of a user name, select the TRACKSIDE button. The TRACKSIDE screen with four buttons is displayed.

5.6 Select the READ BALISE button. Inter-connection checks are performed; PC to BEPT reader connection present and correct, BEPT to balise connection NOT present. STATUS = "Connection Check":

If the PC to BEPT reader connection is faulty:

- RESULT = "FAILED, PC to BEPT connection faulty", and the read operation is halted.

If the connection between the BEPT and the balise is present:

- RESULT = "FAILED, BEPT to Balise cable connected", and the read operation is halted.

If the two connections are correct:

- RESULT = “Connection OK”

5.7 The user is prompted to enter the ID number of the balise being read. The OK button is enabled only if an ID has been entered in the Balise ID text field. No more than 14 characters can be entered.

5.8 Clicking on Cancel removes the popup, stop the current process and re-enable all buttons, RESULT = “Cancellation of Balise ID selection”.

5.9 The BEPT telepowers the balise. The balise transmits the telegram data currently held in memory, and the BEPT receives and logs this data. STATUS = “Reading via airgap”.

if no telegram data is received:

- RESULT = “FAILED, no telegram received via airgap” and the read operation is halted.

If telegram data is received:

- RESULT = “Read operation OK”. Note: If the airgap read operation is successful, the STATUS and RESULT fields might change too quickly to notice.

5.10 The received telegram file is submitted to a coding strategy check, STATUS = “Telegram Coding Check”.

If the coding strategy check fails:

- RESULT = “FAILED, telegram file corrupt” and the read operation is halted.

If the coding strategy check is passed:

- RESULT = “PASSED, balise read successful”. This result confirms that a non-corrupt telegram is stored within the balise, and the balise is functional.

6. Checking Telegram Coding

6.1 Power up the PC and monitor.

6.2 After start up and the entry of a username, select the TELEGRAM CHECK button. The TELEGRAM CHECK screen with two buttons is displayed.

6.3 Select the TELEGRAM CHECK button. The Result and File name fields are cleared.

6.4 Files directory is displayed, Select the telegram to be programmed either from an inserted Floppy Disc or if the telegram is in the local memory of the BEPT carry out this process:

a) When prompted to insert a Floppy Disk click [Cancel].

b) A file browser window pops up which defaults to the desktop, browse the folders on the PC to the stored location and select the telegram to be programmed.

NOTE: *Selection of the file browser window Cancel button closes the file browser window, stop the current process and re-enable all buttons, RESULT = "Cancellation of TGM file selection".*

6.5 A single telegram file or multiple telegram files, in a single directory, may be selected by highlighting them and selecting Open. Selection of multiple directories is not possible.

6.6 Clicking on the file browser window Cancel button closes the file browser window, stop the current process and re-enable all buttons, RESULT = "Cancellation of TGM file selection".

6.7 Once selected, the file browser window closes, and each selected telegram file is checked in turn. The FILENAME field displays the telegram filename currently being checked.

If the current file passes the telegram check:

- RESULT = "Telegram File OK". Note: If the check operation is successful, the FILENAME and RESULT fields might be updated too quickly to notice.

If the current telegram file is corrupt i.e. the check fails:

- RESULT = "FAILED, telegram file corrupt".

A popup is displayed detailing the filename of the corrupted telegram, and a prompt for the user to select the OK button to continue.

Once OK is selected; the check on the remaining files recommences until complete. If other corrupt telegram files are encountered, the error message and popup are repeated.

When all selected telegram files have been checked,

If all the selected telegram files have passed the coding check:

- RESULT= “PASSED, all telegram files correct”, FILENAME = name of the last telegram file checked.

If X number of telegram files have failed the coding check:

- RESULT = “FAILED, X telegram file(s) corrupt”, FILENAME = name of last telegram file checked.

7. Closing Screens and Shutting Down

7.1 Select START – SHUT DOWN

7.2 Select Shutdown in the popup menu.

SECTION D – TRACKLINK III READING AND TESTING

Further information can be found in Tracklink III HSD2300_095-SWT (Tracklink III Beacon Programmer and Tester).

1. Checking the Programmer / Test Tool

1.1 Switch on the portable tag programmer / tester tool at the power on button by pressing and holding for 4 seconds.

1.2 After a short power up period, the display shows the standard windows start up screen.

1.3 Confirm that the antenna is connected to the USB port on the Left side of the tablet. To run the Tracklink III Software program double tap on the icon.

Figure 31 – Tracklink III Icon

1.4 Prior to reading an installed beacon, check that the reader is functional, by using the supplied Test Tag.

1.5 Connect the antenna, place the Test Tag on top of the antenna and select the 'Read Tag' button. '1264400C6300' should be displayed in the Page 1 field on the PC screen.

1.6 Once the Programmer / Tester has successfully read the test tag, locate the beacon to be tested / programmed.

1.7 Place the antenna over the centre of the beacon and within 0.8m of the beacon under test and select the "Read Tag" button.

NOTE: *Check no other beacons or test tags are within 2 metres of the beacon.*

1.8 To clear the data that has been read from a previous tag, select 'Read Tag' with the antenna facing away from the tag. This clears the tag data.

1.9 If any of the tags are not read, repeat the process, if unsuccessful, verify programmer/tester operation by reading the red test tag. If operation with the red test tag is okay, then the beacon might need replacing. Refer to Tag Reading/Verifying Flowchart for further details.

2. Programming a Tracklink III Beacon

2.1 Programming is required when there is a need to create a new beacon for replacement of a faulty beacon.

2.2 To write a beacon, the Operator first Logs on. Select the 'Logon' button, and the logon window appears.

2.3 Enter 'PASSWORD' in the password field and select 'OK'.

2.4 Once logged on, the 'Open File', "Write Tag', 'Log Off" buttons become available.

2.5 Select the 'Open File' button, this should open the 'Master File' (Default), if not, select the 'Set Root Directory' button and select the 'Master File' for use.

***NOTE: Master (Default)** — The master directory contains data which are the files that are* to be used for programming the beacons.

***NOTE: User** — The user directory is available if files need to be saved i.e. for investigative purposes.*

2.6 A window displaying a list of data files (abbreviated by station, platform and platform end) is displayed. Double tap the required file on the list with the Programmer/Tester stylus.

Once a file has been selected, locate the beacon to be programmed, place the antenna directly on top of the centre of the beacon and select the 'Write Tag' button to program the new beacon with the required data.

***NOTE:** Check no other beacons or test tags are within 2 meters of the beacon under test. The Programmer/tester is designed to test/read/write only one beacon/tag at a time and two beacons/tags in close proximity affect its ability to write.*

2.7 Confirmation that the pages (address) 0001 to 0007 have been written show as 'Pass'.

2.8 Confirmation that the correct data has been written to the beacon/tag may be obtained firstly by repeating the 'Read' function and confirming Page 1 and the "Operational Data, are correct, then by pressing the 'Verify' button.

2.9 In the "Verification of Written Data Screen", check the data in address 000F begins with 0314, the "Hex Data" for addresses 0001 to 0004, match "Page 1", data and that addresses 0005 to 0007 equals 0000000000000000.

NOTE: *by pressing the "Verify" button, the data contents of all pages in the beacon/tag is displayed and then, the "Lock" button is available to use, as shown below in Screen-8.*

NOTE: The Lockinq process sets the beacon/taq data to read only and cannot be chanqed once the beacon/taq has been locked!

2.10 Once the beacon/tag has been successfully written, and subsequently verified as correct using the "Read" button then the "Verify" button, the beacon/tag data, can then be locked.

NOTE: The Lock process sets the beacon/tag data to read only, and cannot be changed again!

2.11 If the beacon/tag has NOT been successfully written, an error message appears when using the "Verify" button. If the "Verification Failed" message appears, repeat the process to re-write the data to the tag/beacon.

Once the beacon/tag has been successfully written, select the 'Lock' button. A prompt window shall be displayed as shown below in Screen-10.

NOTE: The "Lock" button is unavailable until the beacon/taq data has been verified usinq the "Verify" button.

2.12 Confirm that the unique beacon/tag serial number and 'Page 1' Hex Data are correct before selecting 'Yes'.

2.13 When the beacon/tag has been locked, an asterisk shall appear next to each page in the event window, and the "Lock" button becomes unavailable to use.

NOTE: This beacon cannot now be re-programmed, if it has been incorrectly programmed and locked by selecting the incorrect file. It should be quarantined immediately to avoid the accidental installation of an erroneous beacon.

2.14 Following the tag write & lock process, the operator can select "Read Tag" and confirm that the data has been written successfully.

END

1. General

This module contains guidance on three types of Instead Logger the 3, 64 and 64 Active. Confirm which type you have before proceeding.

2. Instead Data Logger Disk Analysis

2.1 After a failure / incident, and when instructed to do so, the logger disk should be removed and replaced by the attending staff.

2.2 The logger disk should be analysed by staff competent to Level 2 or equivalent.

2.3 If the disk has been changed as part of routine maintenance, it should be checked to confirm each channel is recording correctly and that the time / date is correct.

2.4 Each disk should be marked with the site name.

2.5 If the disk has been removed as part of an Investigation then in addition to the checks listed above consideration should be given as to what is known to have occurred (by what is recorded on the disk) and what testing is required to eliminate any possible causes not covered by the data on the disk.

For example, the fact that a lamp proving relay is energised does not mean that the lamp is lit, a fault in the tail cable can cause sufficient current flow to energise the relay but prevent the lamp from lighting.

This kind of analysis can both focus and reduce the amount of testing required.

2.6 Copies of the data relating to WSF / incident investigation, shall be submitted as evidence along with any other supporting test records.

3. Remove or Replace an Instead Logger Disk

(All Types)

3.1 The unit depends on having a usable disk in the drive for correct operation.

3.2 Recording always continues into the memory, even when there is not a disk in the drive.

Be aware that if the unit is left without a disk for a long time, the memory eventually fills up. If this happens, data is lost and an ‘overrun’ error message is be added to the system event log.

3.3 Never eject the disk from the drive without first pressing the ‘Change Disk’ button and waiting for the unit’s instructions. The unit stores events in memory until it has stored 256 events, at which point it writes them to the disk.

3.4 When ‘Change Disk’ is pressed, any events remaining in memory are written to the disk. If the disk is removed without pressing ‘Change Disk’ button, the last events are not be recorded. Also, the system event log is not updated on the disk.

3.5 The unit might not respond immediately to your press of the ‘Change Disk’ button under the following conditions:

a) If it is currently writing to the disk, it does not respond until the disk write is completed. This can take up to 2 seconds.

b) If the unit is in menu mode, this should be exited before the disk can be changed. Keep pressing ‘No’ until the time is displayed, then press ‘Change Disk’ again.

c) If the modem link is in use, the unit displays “Logging out remote user - WAIT”. The remote user is then logged out at the end of their current operation. This can take some time.

4. Changing the Logger Disk

For Instead Logger type 3 and 64 (Only)

4.1 A 720K formatted disk is required to replace the one which is currently in the unit. It does not necessarily have to be blank, but anything on it is erased.

For Instead Logger type 64 Active (Only)

4.2 A 1.44M formatted disk is required to replace the one which is currently in the unit. It does not necessarily have to be blank, but anything on it is erased.

All Types

4.3 Before starting the disk changing procedure, the site name and the current date and time shall be written on the label of the new disk.

4.4 If the unit is in a location case, take steps to reduce the ingress of moisture and dirt while the front door is open.

4.5 Open the transparent door on the front of the unit and press the ‘Change Disk’ button. The unit displays:

a) Writing disk WAIT (Type 3 & 64) or

b) Appending data (Type 64 Active).

The unit is writing any left-over events from its memory onto the disk. After a second or so, the display changes to:

c) Remove disk now (Press no to cancel)

Press the eject button on the disk drive and remove the disk.

While there is no disk in the unit, it beeps quietly to remind you to put a new disk in. If you take more than 2 minutes to replace the disk, the beeping becomes more urgent. You can lose data if you leave the unit without a disk for too long.

4.6 The display now shows:

a) Disk removed insert new disk (Type 3 & 64) or

b) Insert formatted 1.44m disk (Type 64 Active).

Take the new disk and insert it into the drive, with the label facing towards the display. As soon as the disk clicks into the drive, the display changes to:

c) Checking Disk

4.7 The unit is now checking the disk to make sure it is correctly formatted, whether it has any data on it, and if there are any faults on it.

4.8 If the disk is OK and is blank, the unit clears the screen and returns to displaying the time and date.

5. Data on Disk

For Instead Logger type 3 and 64 (Only)

5.1 If Data is found on the entered disk the following messages are displayed, depending on the results of the disk check.

a) Disk is not Blank OK to Erase?

The disk has got some DOS or Windows data on it. Press ‘Yes’ to wipe the disk, or ‘No’ if you want to remove the disk and try another. If you do not respond at all, the unit wipes the disk after 60 seconds.

b) Disk is from another logger, OK to erase?

The disk has previously been used in another Instead 3 unit and might have recorded events on it.

If you press ‘Yes’, the unit wipes the disk.

If you press ‘No’, the unit asks you to replace the disk with another one. If you do not respond at all, the unit wipes the disk after 60 seconds.

c) Old disk from this logger, OK to erase?

The disk has previously been used in this Instead 3 unit and might have recorded events on it.

If you press 'Yes', the unit wipes the disk.

If you press 'No', the unit asks you to replace the disk with another one.

If you do not respond at all, the unit wipes the disk after 60 seconds.

d) Instead data on disk, add data on to end?

The disk has just been removed from this Instead 3 unit (the disk you have put in is the one that you just took out).

If you press 'Yes', the unit carry's on recording on the same disk, adding new events onto the end of the previous ones.

If you press 'No', the unit asks whether you want to wipe the disk (press '9') or replace it (remove the disk).

If you do not respond at all, the unit carry's on using the disk, adding new events on the end of the file.

If you change your mind after removing a disk, or if your replacement disk turns out to be unsuitable, this option allows you to put the original disk back in. No data is lost.

<u>Instead 64 Active Logger Disk (Only)</u>

5.2 The disk contains DOS, Windows or unknown file(s). After 4 seconds the display asks for removal of this disk.

a) New config on disk. Update my config?

The disk contains the same site and new site configuration details.

Press 'Yes' to change the system configuration, or press 'No' to cancel.

The unit asks for confirmation and if there is no response within 30 seconds, the new system configuration is loaded and used as the new default.

b) Old config on disk. Change my config?

The disk contains the same site and old site configuration details.

Press ‘Yes’ to change the system configuration, or press ‘No’ to cancel. The unit asks for confirmation and if there is no response within 30 seconds, the new system configuration is loaded and used as the new default.

c) Change my config to Blank Site

The disk contains another site configuration details.

Press ‘Yes’ to change the system configuration, or press ‘No’ to cancel.

The unit asks for confirmation and if there is no response within 30 seconds, the new system configuration is loaded and used as the new default.

d) Use this disk as a data disk?

The disk contains the same site and new site configuration details.

The unit then requires confirmation to use this system site configuration disk as a site data disk.

Press ‘Yes’ to erase this disk and use it as a data disk, or press ‘No’ to cancel.

The unit asks for confirmation and if there is no response within 30 seconds, the unit then examines the disk to determine what files are present and if any errors exist on the disk.

e) Data already on disk 9-Erase Y-Keep

The disk has previously been used in this Instead 64 Active unit and might have events on it.

Pressing ‘9’ erases the disk.

By pressing ‘Yes’, the unit appends any events onto the end of the last event on the disk.

If there is no response after 30 seconds, the unit assumes that ‘Yes’ was intended.

f) Erase all I64 files on disk?

This message requires confirmation before erasing a disk.

Press ‘Yes’ to wipe this disk, or press ‘No’ to cancel, whereupon the unit prompts you to remove of the disk and waits for the disk to be removed.

g) Verify disk? (recommended)

This message requires confirmation before verifying a disk, i.e. checking the disk for any bad sectors.

This process can take up to 90 seconds.

Press ‘Yes’ to verify the disk, or press ‘No’ to cancel.

The unit verifies the disk after 30 seconds if there is no response to this message.

6. Disk not Usable

For Instead Logger type 3 and 64 (Only)

6.1 If the disk is unusable the following messages are displayed, depending on the results of the disk check.

a) Disk is wrong format, please replace

The disk is not 720K DOS formatted (it might be formatted at the wrong capacity or not formatted at all).

The unit cannot use the disk, it is to be replaced.

This message is accompanied by a fault indication, which is cancelled automatically when you remove the faulty disk.

b) Disk has bad sectors, please replace

The unit has detected some bad sectors on the surface of the disk. The unit cannot use the disk, it is to be replaced. This message is accompanied by a fault indication, which is cancelled automatically when you remove the faulty disk.

Place the new disk into the drive, with the label towards the display.

The display clears to show the current date and time.

Recording continues as normal.

Instead 64 Active Logger Disk (Only)

6.2 If the disk is unusable the following messages are displayed, depending on the results of the disk check.

a) Disk wrong format or bad sectors

The disk is not 1.44MB DOS formatted or the unit has detected some bad sectors.

It might be formatted at the wrong capacity or not formatted at all.

The unit cannot use the disk, it is to be replaced.

This message is accompanied by a fault indication, which is cancelled automatically when the faulty disk is removed.

b) Error reading disk directory

An error occurred while reading the disk. After a few seconds the unit requests the removal of the disk.

c) Load config failed. Blank Site

An error occurred while reading system configuration from the disk. The unit displays an error message and any code(s).

d) Disk error xxxxxxxxxxxx

After a few seconds the unit requests the removal of the disk.

e) Error writing config Disk write protected

An error occurred while reading system configuration from the disk.

The unit displays an error message and any code(s).

f) No. of channels = xx Incorrect!

The system configuration site disk contained an incorrect number of channels in the set-up file(s).

The display shows the incorrect number of channels on this disk.

This site configuration disk is ignored.

After a few seconds the unit requests the removal of the disk.

7. After the Disk has been changed

All Types

7.1 Write the current date and time on the removed disk and check the site name is also marked on it.

7.2 Close the front door of the unit.

END

1. Replacing Control and Evaluation Unit Components

1.1 All Control and Evaluation Unit components are replacement parts and cannot be repaired.

1.2 The UPS is an exception to this as the spent batteries can be replaced. This task shall only be undertaken by specialist personnel.

1.3 Any item requiring replacement should be replaced using the correct SMTH Test Plan.

2. Start-up Procedure

2.1 Connect the load with the UPS system without switching them on. Make sure that the UPS system has two groups of output sockets. The programmable output sockets can be switched independently of the remaining sockets. The programmable output sockets are primarily designed for less critical load which cannot be brought down using software. Critical load should not be connected to the programmable output sockets.

2.2 Connect the power supply cable (supplied with the XANTO 2000 and 3000) for the UPS system into a socket. The display on the UPS system shows “Sb”,

2.3 Hold the “ON / 🔇 / ▲” button on the UPS system down until you hear a short beep.

2.4 The UPS system carries out a self-test, after which “OK” appears on the display. The UPS system is now operating in normal mode and supplying the load with reliable power.

2.5 If an additional emergency power off switch has been installed, the emergency stop function needs to be tested.

2.6 Switch the load on one by one.

NOTE: *The internal batteries charge up to 90% of their full capacity in less than four hours. ONLINE recommends charging the batteries for 48 hours after installation or extended periods of non-use.*

The batteries start to charge as soon as the UPS system is connected to the supply network and supplied with power, irrespective of the operating mode.

3. Starting in battery mode

3.1 Hold the “ON / 🔇 / ▲” button on the UPS system down until you hear a beep.

3.2 The UPS system is starting; the display then shows the battery status and supplies the load connected with reliable power.

3.3 If the display is lit, fix all warnings and restart the UPS system.

4. Switching off

4.1 Hold the “OFF / ” button on the UPS system down for 2 seconds. When the continuous beep ends, the UPS system switches to standby mode.

NOTE: *If the “OFF / ” button is released after less than 2 seconds, the unit is not switched off.*

4.2 Disconnect the mains connection cable of the UPS system from the socket. The display on the UPS system goes out after a short time and the UPS system switches off completely.

5. Replacing an EPOS Unit

<u>Unregistering and removing the defective EPOS-Unit</u>

5.1 Open the EPOS configuration by double-clicking on the SAT GUI icon. First a login window appears.

5.2 Enter the login data.

5.3 The EPOS configuration window opens:

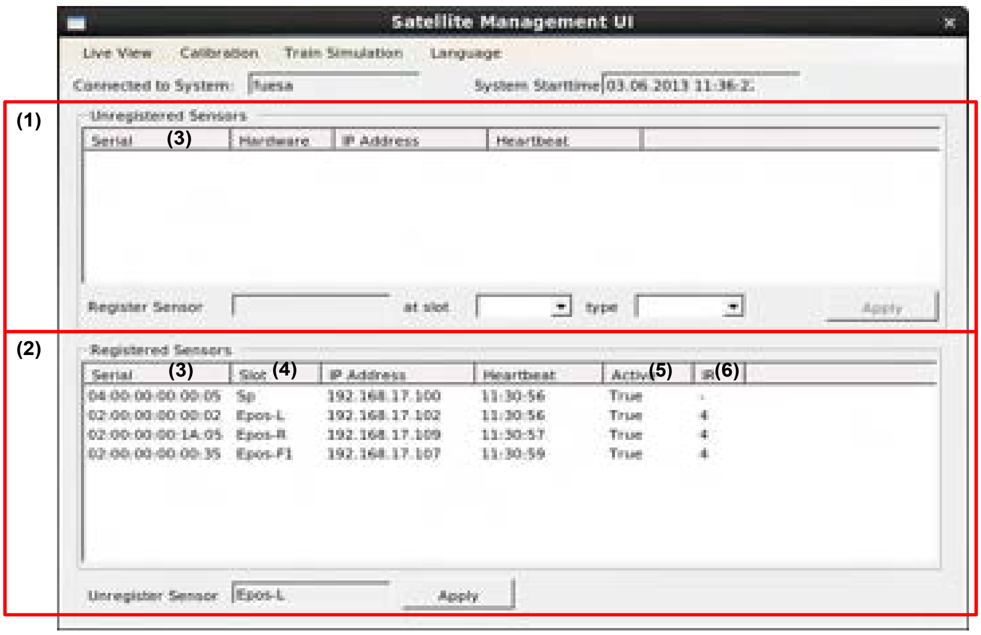

Figure 1 - "EPOS configuration" window

Number	Function Description
(1)	"Unregistered Sensors" area (SLSC modules as EPOS units, SP board).
(2)	"Registered Sensors" area (SLSC modules).
(3)	"Serial" column: Display of the MAC address.
(4)	"Slot" column: Display of the functional allocation (e.g., measurement position) of the sensors.
(5)	"Active" column: Display of the connection status.
(6)	Number of detector elements (for EPOS units).

Table 1 – Key to Figure 1

5.4 Unregister the defective EPOS-Unit:

a) Select the defective EPOS-Unit in the "registered sensors" at the bottom.

b) Click on the "Apply" button (item (1) in Figure 2).

The module that has been unregistered disappears in the "registered sensors" area at the bottom and now appears in the "unregistered sensors" area at the top.

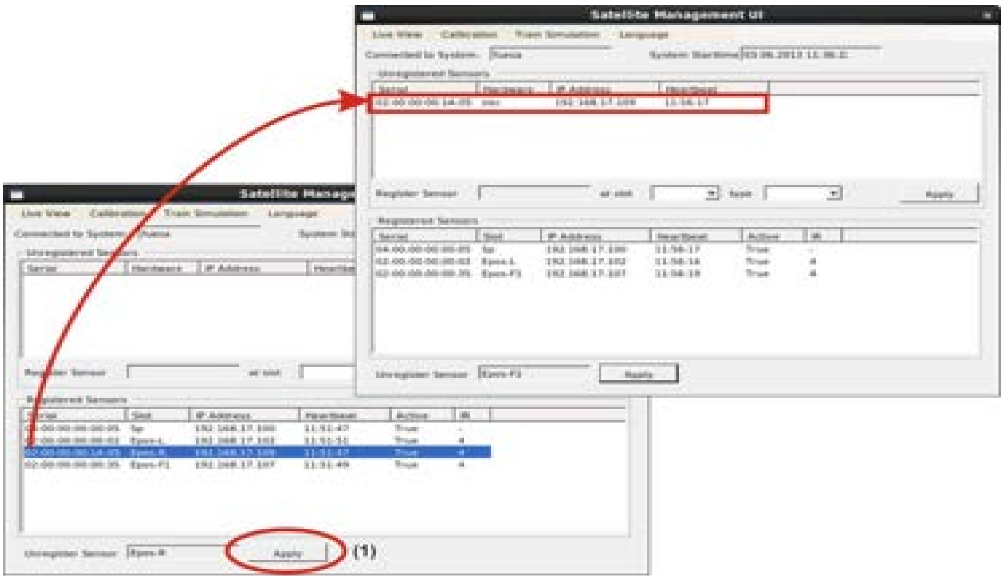

Figure 2 - Logging out the defective EPOS-Unit

Removing the HBD EPOS-Units

5.5 Loosen the two bolts of the inner cover plate (Figure 3, marked (1)) and slide the plate (Figure 3, marked (2)) away from the HBD, in the direction of the red arrow.

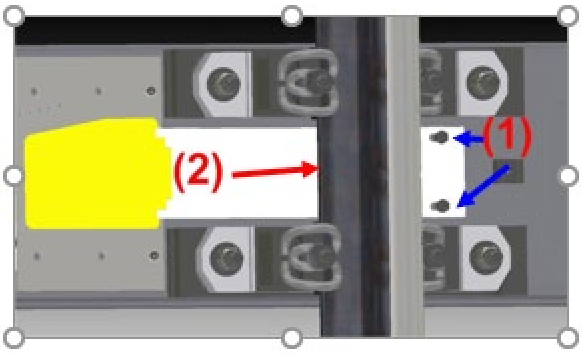

Figure 3 – Removal of the Inner Cover Plate

5.6 Loosen and remove the HBD-L and HBD-R EPOS-Unit fastening screws (each of four M12, SW19 screws, with washer and spring-lock washer) on the base plate and remove. See Figure 4.

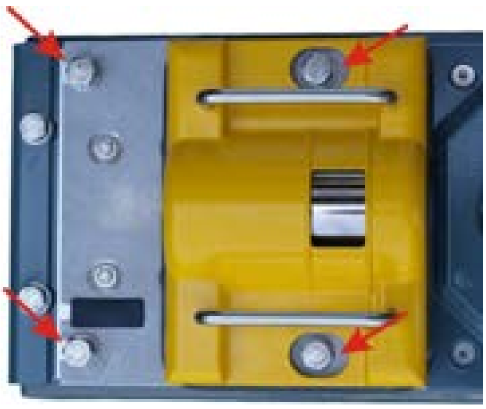

Figure 4 - HBD EPOS-Unit screw connections

5.7 Pull both HBD EPOS-Units out of the measuring sleeper and move them downwards using the shutter, putting them onto or next to the measuring sleeper (see Figure 5).

- Do not loosen the long cable.
- Do not unscrew the adjustment frame.

Figure 5 - HBD EPOS-Unit placed on the sleeper

5.8 If the EPOS Unit is being disconnected/removed from site or replaced, push the plug protection to one side and disconnect the plug connection.

The entry for the EPOS-Unit which has been disconnected shown in the "unregistered SLSC modules" area (seen in Figure 2) disappears.

5.9 Secure and protect the disconnected ends of the cable.

Re-assembly of the HBD EPOS-Units

5.10 If the EPOS Unit is being re-connected after being removed from site or replaced, reconnect the cable and replace the plug protection.

5.11 Re-insert the HBD EPOS units into the measuring sleeper.

5.12 Grease the screws before assembly to protect them from corrosion.

5.13 Reposition the inner cover plate so there is no gap at the HBD (Figure 6).

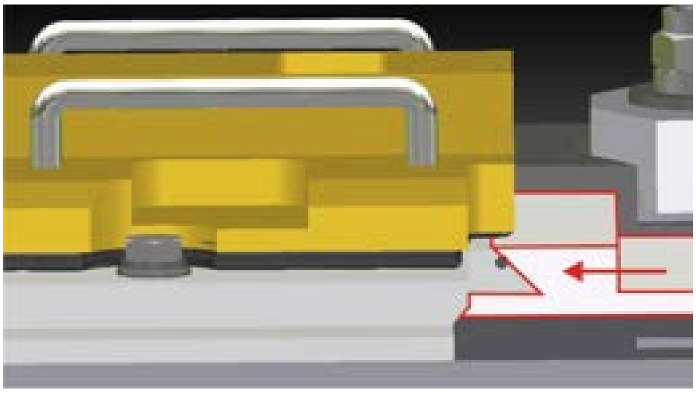

Figure 6 - Inner Cover Plate Replacement

5.14 Fasten the HBD EPOS unit with the M12 x 45 mm screws, including the washers and spring rings (tightening torque 70 Nm).

5.15 Confirm while doing so that the plug protection is not moved out of place.

(1) Position of the plug connection inside the plug protection
(2) Plug protection assembled in the correct position

Figure 7 - Plug protection

Removing the HWD EPOS-Unit

5.16 Loosen and remove the HWD EPOS-Unit fastening screws (each of four M12, SW19 screws, with washer and spring lock ring) on the base plate and remove. See Figure 8.

5.17 Pull the HWD EPOS-Unit out of the measuring sleeper carrier and move it downwards using the shutter, putting it onto or next to the measuring sleeper (see Figure 9).

Figure 8 - HWD EPOS-Unit screw connections

5.18 If the EPOS Unit is being disconnected/removed from site or replaced, push the plug protection to one side and disconnect the plug connection.

The entry for the EPOS-Unit which has been disconnected shown in the "unregistered SLSC modules" area (seen in Figure 2) disappears.

5.19 Secure and protect the disconnected ends of the cable.

Figure 9 - HWD EPOS-Unit placed on the sleeper

Re-assembly of the HWD EPOS-Units

5.20 If the EPOS Unit is being re-connected after being removed from site or replaced, reconnect the cable and replace the plug protection.

5.21 Insert the HWD EPOS unit into the measuring sleeper.

5.22 Grease the screws before assembly to protect them from corrosion.

5.23 Fasten the HWD EPOS unit with the M12 x 45 mm screws, including the washers and spring rings (tightening torque 70 Nm).

5.24 Confirm while doing so that the plug protection is not moved out of place.

Registering the EPOS unit

5.25 If you are not already logged into the "Satellite Management UI" system, open the EPOS configuration by double-clicking on the icon and logging in when the login window appears.

5.26 The new EPOS-Unit (SLSC module) appears automatically in the "unregistered sensors" area at the top as soon as it is plugged in.

5.27 Assign the new EPOS-Unit (SLSC module) to the previous function (measurement position) by following steps:

a) Open the “at slot” drop-down list as shown in Figure 10, and select the measurement position.

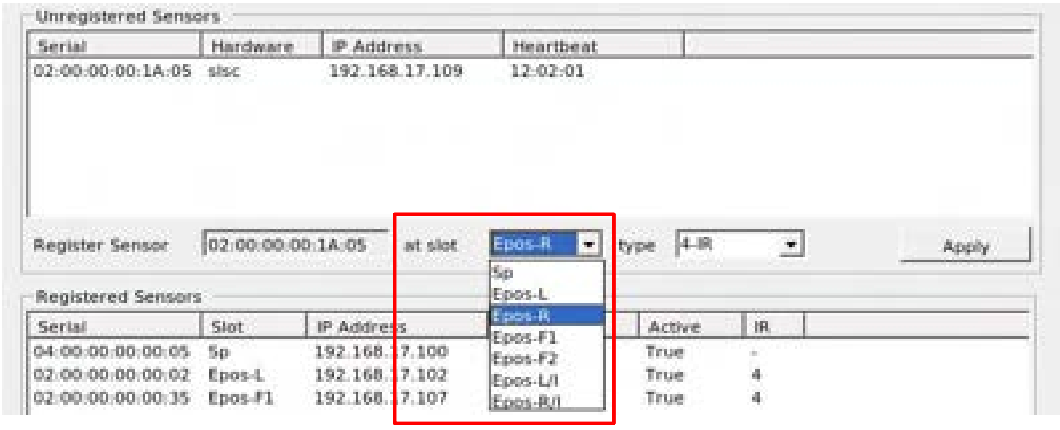

Figure 10 - Assigning the EPOS-Unit to a measurement position

b) If necessary, change the detector type (4 or 8 elements) using the "Type" drop-down list.

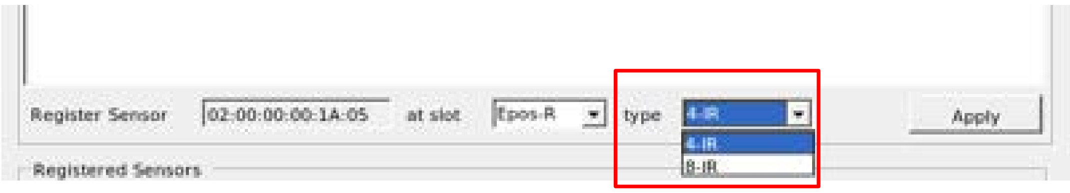

Figure 11 – Selecting the detector type

c) Mark the new EPOS-Unit (SLSC module).

d) Click on the "Apply" button (item (1) in Figure 12).

5.28 The new EPOS-Unit disappears from the "unregistered sensors" area at the top and now appears in the "registered sensors" area at the bottom.

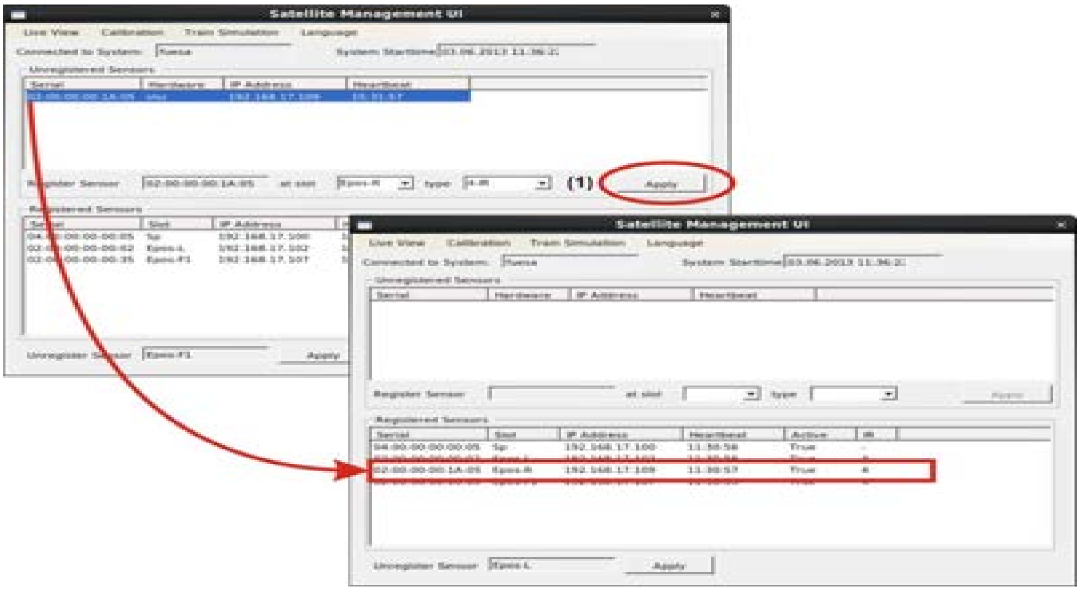

Figure 12 - Logging in the new EPOS-Unit

5.29 The new EPOS-Unit (SLSC module) is now registered in the FUES-EPOS system.

5.30 Check the connection status of the EPOS-Unit in the "Active" column. If "True" appears in this column, the connection is OK.

<u>Transferring calibration data of the new EPOS-Unit</u>

5.31 Open the EPOS configuration by double-clicking on the icon. The "EPOS configuration" window opens:

The following actions can be reproduced in the screen shown in Figure 13.

a) Click on the "Calibration" menu.

b) A pull-down menu opens.

c) Move the mouse pointer to the "Read Curve from Satellite" menu item.

d) A pull-down list for selecting an EPOS-Unit opens simultaneously.

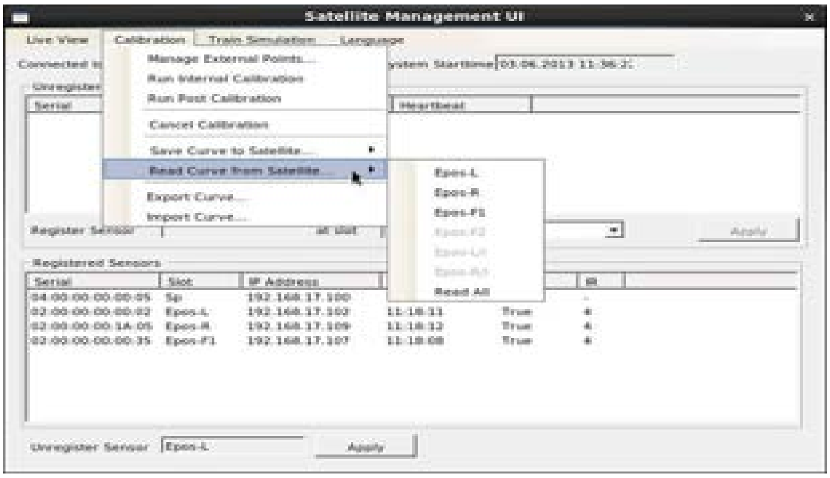

Figure 13 - "Internal Calibration" pull-down menu

5.32 Move the mouse pointer to the EPOS-Unit you want in the pull-down list and start the calibration data transfer with a mouse click.

The progress of data transfer is displayed.

Figure 14 - Data transmission progress display

All the calibration data of the new EPOS-Unit has now been transferred to the system database.

5.33 Carry out NR/SMS/PartB/Test/180 (EPOS - Manual Post Calibration Test).

6. Wheel sensor RSR123

6.1 Remove the wheel sensor in the following order:

a) Loosen connector flange and remove connection cable.

b) Mark the exact position of the rail clamp on the rail.

c) Dismantle the rail claw together with the wheel sensor from the rail.

d) Remove the fastening screws of the wheel sensor.

6.2 Re-installing the wheel sensor in the following order:

a) Attach the new wheel sensor to the rail claw.

b) Tighten the fastening screws according to the installation instructions for the wheel sensor manufacturer.

c) Screw the wheel sensor together with rail claw on the previously marked position on the rail.

d) Perform position control of the wheel sensor at the rail.

e) Re-mount the connection cable and the connector flange.

6.3 Carry out NR/SMS/PartB/Test/184 (EPOS – RSR123 Wheel Sensor Voltage Adjustment).

6.4 Carry out NR/SMS/PartB/Test/181 (EPOS - Wheel Sensor Occupancy Detection Capability Test).

END

1. Replacement Sequence

1. Before removal of the old circuit controller, check that the machine is placed into the approximate mid-stroke position.

2. Check that each wire is identifiable as it is removed. If this is not the case, check the installer correctly marks/identifies the unidentifiable wires as they are removed.

3. Check that the installer unlocks the two locking plates, removes the four bolts securing the machine and lifts the circuit controller clear of the machine.

4. Check that the installer removes the ballscrew cover and uses the datum marks on the machine driveslide, located under the ballscrew cover, to confirm that the machine is in mid-stroke (Figure 1).

5. Check that the installer identifies the space between teeth 16 and 17 of the toothed rack (counting from either end) and makes a mark from the rack to the edge of the case of the machine (which can be seen once the circuit controller is offered up).

6. Check that the installer inserts two new pushrods into the circuit controller with the step faces uppermost and the large washers outside the controller chassis.

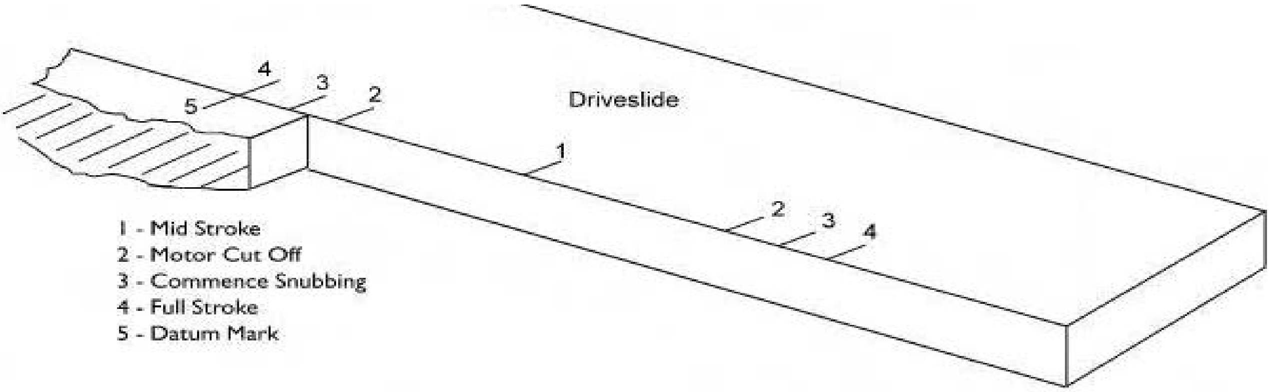

Figure 1 – Drive Slide Position Points

7. Check that the installer rotates the shaft on the controller.

   NOTE: *the moulded arrowhead mark on the rim of the nylon gear wheel is positioned at 6 o'clock with the gear wheel just clear of the toothed rack.*

8. Check that the installer inserts the two pushrod ends into their respective operating levers and moves the circuit controller sideways to compress the detector pushrod springs.

   NOTE: *The moulded arrowhead mark on the gear wheel is directly above the marked space between teeth 16 and 17 on the rack.*

9. Check that the installer lowers the controller onto its support pillars and replaces the four bolts using new locking plates.

10. Before the installer finally tightens the bolts, check that the moulded arrowhead mark on the gear wheel is aligned with the mark next to the rack.

    Check both the detector pushrods can be freely pushed into the circuit controller and that their return springs operate correctly.

    NOTE: *the pushrods sticking indicate improper alignment with the rotary lock detection segments. Remedy is by slacking off the four bolts and moving the circuit controller slightly sideways within the tolerance/clearance permitted between the four bolts and the holes in the circuit controller chassis through which they pass.)*

11. Check the installer tightens the bolts and turns up the locking plates.

12. Crank the machine to one end of its stroke and check that the pushrod roller is resting on the bottom of the detector blade notch, clear of the sloping cam face.

13. Insert 2mm gauge (Figure 2) between the roller and the bottom of the detector blade. Check the detection contacts just break. If necessary, adjust the nuts on the pushrod.

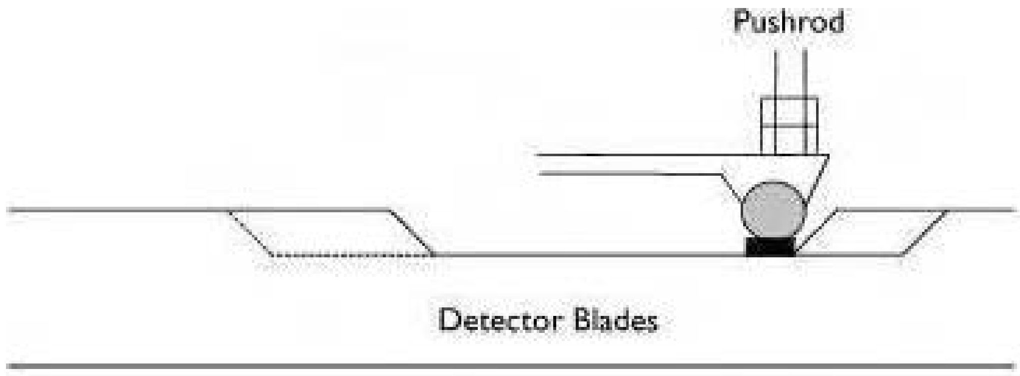

Figure 2 – Positioning of the 2mm Gauge

14. Crank the machine to the other end of its stroke and repeat steps 16 and 17.

15. Check that both nuts on each pushrod are fully tightened.

16. Crank the machine to mid-stroke.

17. Check the nominal 1mm gap on the quick acting motor cut-off contact (Figure 03).

18. If adjustment is required, loosen the 0BA nuts of the stud terminals and slide the moveable contacts as necessary.

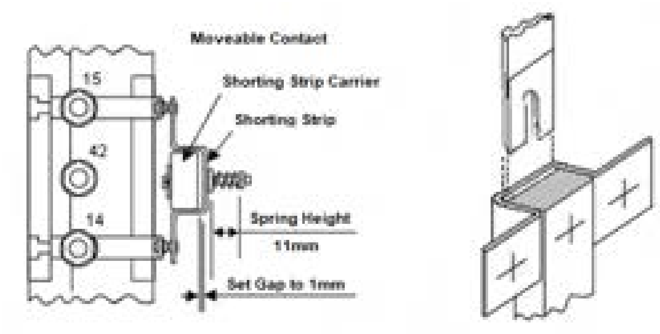

Figure 3 – Cut Off Motor Contact Details

19. Previous circuit controller changes have not always resulted in marks 2 and 3 on the driveslide of the machine being altered.

    However, the mid-stroke mark 1 is correct. The following process allows for the marks 2 and 3 not necessarily being in the correct place.

20. Check that mid stroke to motor cut-off (mark 1 to 2) is 93.5mm to 95mm and motor cut-off to snubbing (mark 2 to 3) is 1.5mm minimum to 3.0mm maximum.

    If the marks are incorrect, make your own marks with pencil or felt tip and use those marks in steps 21 to 24.

    Always crank the machine from mid-stroke towards the setting marks to eliminate gearing backlash.

21. Align mark 2 with mark 5. Check that the motor cut-off contact is just broken.

22. Align mark 3 with mark 5. Check that the snubbing control contact is just made.

    There should be a quarter to half a turn of the crank handle between the cut-off breaking and the snubbing contact making.

23. Check that the lock proving, and detection contacts do not make until 97mm from mid-stroke.

24. Check that the lock proving, and detection contacts are open at least 2mm throughout the whole travel.

25. Repeat steps 21 to 24 for the opposite lie of the machine.

    The detection on the machine is arranged so that the closed switch furthest from the machine is always detected by the roller/pushrod nearest the track, and vice versa

26. Crank the machine to the end of its stroke to close the switch furthest away from the machine. Check that the switch rails are fully closed.

27. Insert a 3.5mm gauge between the pushrod roller and the cam face of the detector blade notch (Figure 4). Adjust the ¾" nuts on the detector rod until the correct detector contacts are just broken.

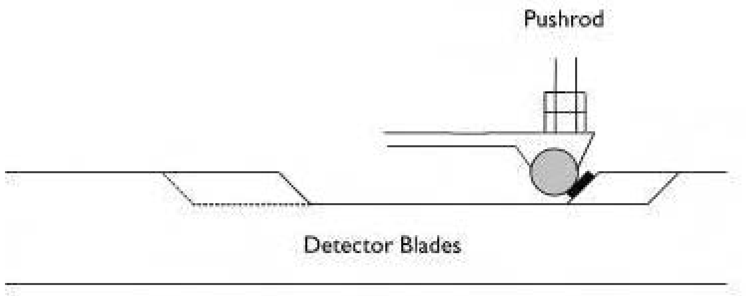

Figure 4 – Positioning of the 3.5mm Gauge

28. Substitute a 2mm gauge, and check that the correct detector contacts remain made.

29. Substitute a 5mm gauge and check that the detection contacts are open by at least 2mm.

    No adjustment of the detection contacts is possible. A new circuit controller shall be fitted.

30. Crank the machine to the opposite end of its stroke. Check the switch rails are fully closed. Repeat steps 27 to 29 for the other pushrod and detector contacts.

31. Check that all relevant nuts are tightened and ballscrew cover replaced.

END

Includes:	Siemens TRAINGUARD FUTUR 2500 Series E Radio Block Centre (RBC) Cubicle
Excludes:	All other type of RBC/RBC Cubicles

GENERAL

Before undertaking any work within an existing/operational RBC cubicle, the Signaller needs to be informed before doing so.

The ESD wrist strap should be worn while carrying out tasks within the RBC Cubicle.

The integrated RBC system is housed in a cubicle with all the associated equipment (Figure 1).

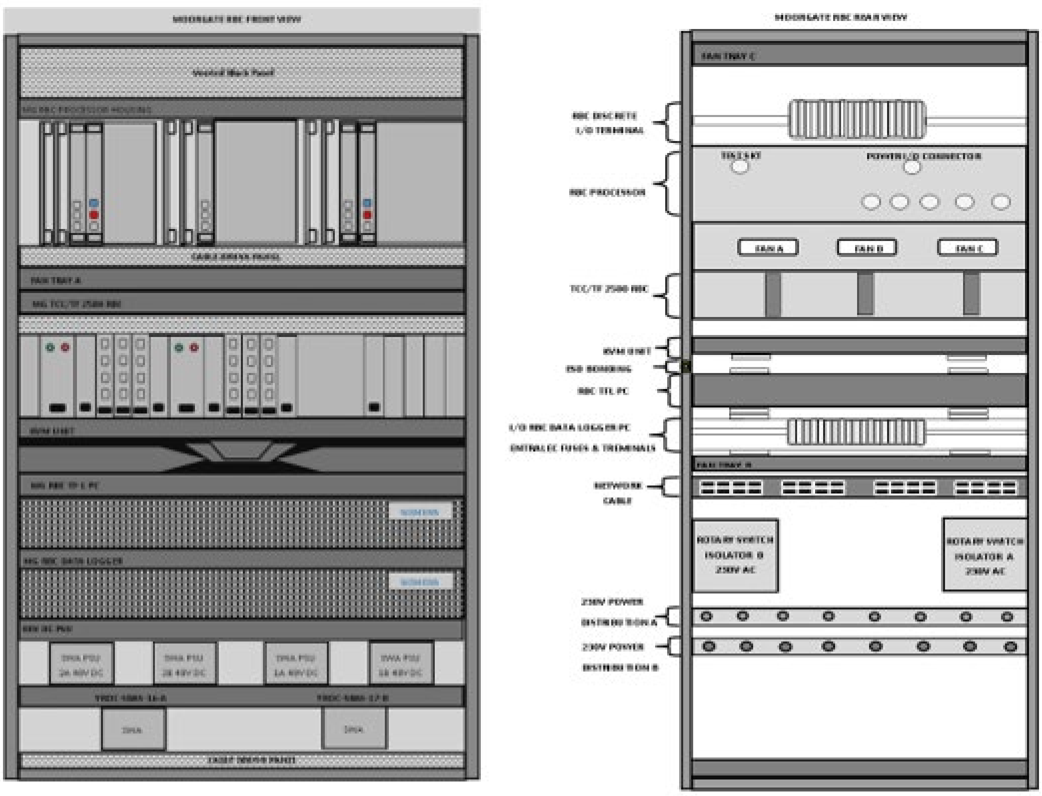

Figure 1 – RBC Cubicle Front and Rear

The TRAINGUARD FUTUR 2500 RBC cubicle is composed of the following elements:

Control Elements:

a) 1 RBC Processor MKII.

Cooling Elements:

a) 3 FAN Tray Modules (1 at the front; centre of the cubicle, 2 at the rear, one at the top, one at the bottom).

Maintenance Elements:

a) 1 KVM. The KVM is made up of:
   - 1 KVM Switch.
   - 1 KVM Rack Console

b) 1 Keyboard

c) 1 Patch Panel

d) Dual TCC Info - The TCC comprises two of each:
   - Power Supply Unit.
   - Processing Card.
   - Quad Fast Ethernet Interface.
   - Memory Card Carrier.
   - ISDN Board.

e) RBC Common Technicians Facility (CTF) – Blue Chip C110 PC.

f) Dual Power Supply Unit (PSU) 48V.

g) 2 Network Switches (SWITCH A and SWITCH B).

h) Dual Power strip 230V AC PSUs – A and B supply.

i) 3 Fan Modules.

j) Moorgate RBC Data Logger PC Blue Chip C110.

RBC RIF:

The RBC-RIF is part of the WESTCAD-E(SS) architecture and is co-located in the ECML South Cubicle and includes the Temporary Speed Restriction (TSR) functionality.

The RBC-RIF will also handle the RBC arming process by passing indications to the Control Centre operator.

RBC Processor:

The RBC Processor is built on Ethernet IP Network (LAN/WAN). This provides flexibility to the system and an easy way to connect the RBC to other vital modules

KVM Switch:

The 'KVM Switch' interconnects the TCC with the 'KVM Rack Console' and the 'Keyboard'.

TCC :

The TCC receives messages from the RBC Processor through the Ethernet interfaces and sends them to the train through the ISDN module.

In addition, it receives messages from the train through the ISDN modules and transmits these messages to the RBC Processor using the LAN network.

The TCC comprises two of each:

- Power Supply Unit
- Processing Card
- Quad Fast Ethernet Interface
- Memory Card Carrier
- ISDN Board

The Server is dual-redundant (CPU A and CPU B), and it is fault tolerant.

Each CPU has got an ISDN Board mounted. "ISDN A" is housed in "CPU A" and "ISDN B" is housed in CPU B.

Common Technicians Facility

This is a local Technician's workstation comprising of a Blue Chip C110 PC loaded with the CTF software. The local TF application is automatically executed when the PC is turned on. The CTF is a diagnostic tool that offers the user fault indications of the system and replay functionality.

Check the name, the software version, the version of the resources and the active username appear in the frame of the main window.

Check the data base has an MDB format and belongs to the installation in which the replay is to be carried out.

Check the main window is configured by, the installation bar, the status bar, the mode selection bar, the replay bar, the action bar and the buttons. These bars enable access to the application functionality.

Power Supplies:

A Dual Power supply Unit (48V) is provided as a back-up to the RBC and Network Switches.

The cubicle is supplied by two 230V AC supplies. Each 230V supply comes into the cubicle via a rotary isolator switch. From the rotary switch, each supply feeds a 230V AC IEC Power Strip (Power Distribution A and B).

The 230V AC Supplies the TF, TCC, Fan Units and the PSUs. The PSUs transform/rectify the 230V AC voltage to 48V DC that supplies the RBC Processors and the Cisco Network Switches. To isolate the 230V AC equipment, the IEC C14 plug should be disconnected from the power distribution units as per application design.

CISCO 16 Port Network Switches SWA and SWB:

This connects with the RBC Cubicle and provides remote communication from YROC

Datalogger (Test tool)

A data-logger will be attached to the RBC via the Network Switches in the same cubicle. This is a test tool and no maintenance is needed to be provided.

NOTE: *When the RBC or CIP is powered down, the ETCS Enable button will need to be pressed as part of the arming process.*

This will be done as per instruction from the Signaller Shift Manager as part of the NCL RBC Start up Process - 156905-SIR-NOT-ESG-000001

END

INDEX

END

General

This Handbook gives information needed to maintain signalling equipment to the necessary standard.

The manual is divided into separate parts as follows:

Part A:

Describes the general responsibilities and conditions for maintaining equipment.

Part B:

Contains the specified tests that are referred to in the signalling maintenance specifications. These are identified in sections A, C, E, & T of this document by means of a hyperlink.

For Example: NR/SMS/PartB/Test/001 (Facing Point Lock Tests (Machine))

Specified tests on assets not owned by signalling are in their designated sections along with the maintenance specification.

Part C:

Contains the approved maintenance specifications for signalling assets. These are packaged as units of work; each unit being designed around a physical asset. If a part or all of that asset is owned by different function (e.g. SPTs on signals) the maintenance specification for that asset is in the relevant section.

Part D:

Contains the indexes and references to the level crossing annual tests (details of how the obtain the annual test documents are detailed here).

Part E:

Contains the approved maintenance specifications and specified tests for assets owned by functions other than Signalling or Telecoms that are maintained by signalling (e.g. HABD systems).

Part R:

Contains the standard NR/SMS record cards associated with the tests and tasks in part B & C.

Part T:

Contains the approved maintenance specifications and specified tests for Telecom assets that are maintained by Signalling.

Part Z:

Contains listings of commonly used voltages and measurements on all assets as a ready reference guide.

Part Appendix:

Contains information on equipment that is not direct preventative or corrective maintenance but provides background information which will assist in carrying out these tasks but is too large or detailed to fit in the generic '00' series of NR/SMS parts C, E, or T.

Each maintenance specification is divided into services, tests, and tasks that relate to the frequency of the maintenance.

The frequency for each NR/SMS service is stated in NR/L2/SIG/10661.

DAILY SERVICES:

Services and/or tasks that are performed daily.

REGULAR SERVICES:

Services, tests or checks that are performed at a frequency greater than daily but can be equal to or less than Service A.

SERVICE A:

Relates to the routine inspection and testing of equipment (typically four times a year).

SERVICE B:

Relates to the heavy maintenance or testing (typically once a year).

SERVICE RA / RB / R1 / R2 / R/3 / R4 or RE:

These relate to the Reliability - Centred Maintenance Tasks, the intervals on these tasks are in excess of the standard frequencies.

PERIODIC TASKS:

Relates to tasks that are carried out periodically (usually between two and five years) as opposed to cyclic. (e.g. periodic tasks might include memory battery replacement on PC boards or returning an item for re-servicing at an approved service centre).

ROLE DESCRIPTIONS:

Role descriptions within NR/SMS refer to Network Rail post and titles. Companies other than Network Rail might use different posts and titles. It is the responsibility of the individual companies to map the Network Rail posts and titles within NR/SMS to the equivalent ones within their own company.

MANDATING OF TASKS AND TESTS:

Some tasks and tests within NR/SMS have the following comments as part of their description:

a) Local Policy Requirement:

b) If provided:

c) If fitted:

If the details of a task or test having this comment are applicable to you, it will be on your work order, or if not your SM(S) will tell you. If you are in any doubt, ask.

Any task that does not have these comments attached to them is mandatory.

IMPERIAL AND METRIC MEASUREMENTS:

Some older signalling equipment (especially mechanical) was designed, built, and installed to imperial measurements.

This also applies to new equipment built in the United States of America (USA).

These do not always easily convert or make sense in metric units. If a piece of equipment is from the ‘imperial’ era, or from the USA, the equivalent imperial measurement is used.

If it is a new piece of equipment metric measurements are used. If you are unsure about any imperial or metric measurements stated in NR/SMS, ask your SM(S).

END

The safe passage of trains is the top priority, if you find any item than can or will affect this, immediate action shall be taken up to and including blocking the line.

More details can be found in GE/RT8000 (rule book).

Preventative Maintenance

The scheduling of preventative maintenance is the responsibility of the maintenance function within Network Rail. This is performed by the Ellipse system which produces work orders.

For signalling, electronic handheld devices are used for scheduling and inputting in place of paper.

Completion or partial completion of any work should be recorded on the electronic "Work orders" or Work Arising Identification Forms (WAIFs) displayed on the handheld device.

Staff carrying out tests that have a related record card(s) should also check that card as all the appropriate details fully completed.

Any work undertaken other than that stated on your work order including any adjustments that have to be made as a result of carrying out a task/test shall be classed as corrective maintenance and dealt with as detailed in the next section.

Inform your SM(S) if you find any conflict between what is stated on your work order, such as:

- asset you have to maintain (e.g. work order states a WRSL 63 point machine but the asset is actually a HW point machine) or
- find an asset that should be maintained but is not on your work order (e.g. the point system has a supplementary drive but there is no job for it on the work order) or
- the work order states maintain an asset that has been removed or the work order states an incorrect job for the asset

If you have any problems or queries with the maintenance you are scheduled to undertake, inform your SM(S).

Corrective Maintenance

Some of the tasks/test within NR/SMS asks you to rectify any defects you find or undertake adjustments, tightening etc. This shall be classed as corrective maintenance.

All corrective maintenance items shall be recorded in Ellipse using the WAIF process. This shall apply to:

- Work identified and completed
- Work identified but not completed
- Work identified that is undertaken by other functions (e.g. Track, E&P etc).

Corrective maintenance items that are causing a failure that will have an impact on the running of trains, shall also be reported to the Integrated Control Centre or Infrastructure Fault Control (both covered by the generic acronym ICC) of the details.

This is so that it can be entered into the Fault Management System (acronym FMS) and appropriate action taken.

End

General

The following terms appear in this Handbook to describe particular actions that should be used when maintaining equipment.

Term	Definition
Brush	Brush all loose dirt from apparatus and foundations using a brush which has no exposed metallic surfaces
Check	Visually inspect for alignment, obstructions, breakages, decay, obvious damage, and/or operation within its defined tolerances, and/or fulfilment of purpose.
Clean	Remove moisture, dirt, corrosion, or roughness (e.g. from contact faces).
Dust	Dust lightly with a brush with no exposed metallic surfaces or duster
Examine	Closely inspect apparatus and connections for wear, security, corrosion, deterioration, decay, and damage.
Isolate	Electrically disconnect from working circuitry as detailed in NR/SMTH/Part-03/Check A05.
Lubricate	Oil or grease parts to reduce friction or provide protection and wipe off excess.
Measure	Apply an approved, calibrated measuring instrument/gauge, then read, and record the result.
Note	Make a physical record of the visible state, the position, or displayed indications of the equipment or item and its associated controls or operating system(s).
Observe	Look at the equipment in use to make sure it is working correctly and is not faulty.
Protect	Apply an approved protecting agent.
Rectify	Make good any faults discovered and/or adjustments required as a corrective maintenance item.
Record	Enter the obtained measurement readings or observations on a suitable record card or in a site log book.
Scrape	Scrape all dirt and surplus grease off apparatus and foundations.
Test or Gauge	Examine apparatus and run it (or use the appropriate tool, gauge or instrument) to make sure it is working correctly and is adjusted within the specification.
Wash	Remove contaminated oils, greases, and dirt by applying an approved cleaning agent, or by using a detergent and water and then drying.
Wipe	Rub apparatus with a cloth to remove dirt, grease etc.

END

General

This single generic method statement covers preventative and corrective maintenance activities and is based on best practice.

It does not supersede any mandated documents you may currently be using (this includes local method statements or risk control sheets) or any local policies.

Your SM(S) shall explain the documents applicable to you. The points to be considered are as follows:

1. Scope of work
2. Competence of staff
3. Safety of staff and briefing arrangements
4. Communications and emergency plans
5. Protection arrangements and equipment
6. Railway and public ‘interfaces’
7. Associated hazards and risks
8. Tools and plant
9. Personal protection equipment
10. Environmental issues
11. Working at height

The following sections explain these main points.

1. Scope of Work

Before starting any activity:

a) Consider all the work involved
b) Check that you are protected by a safe system of work
c) Select the correct maintenance specification
d) Obtain the signallers permission before starting any work that will interfere with signalling equipment.

When you communicate with the signaller, confirm that your and their messages are clearly understood. GE/RT8000 HB1 specifies the requirements for safe communication.

GE/RT8000 HB19 allows you to carry out certain maintenance activities without making an entry in the train register providing that:

a) The work does not affect the safety of train working
b) The work does not affect the normal passage of trains
c) The work can be carried out between trains
d) This generally equates to lubricating and cleaning equipment, taking non-intrusive meter readings.

NR/L3/SIG/10064 (General Instructions to Staff Working on S&T Equipment) section NR/GI/B002 clarifies the permissible work that can be carried out under these circumstances.

GE/RT8000 HB19 does not provide protection for staff. It is only concerned with the protection of trains

Consideration shall be given to systems affected by work on individual items of equipment. For instance, work on a piece of equipment that might affect an erroneous release on a system.

When resetting or restoring equipment back into service, consideration should be given to other systems that will be affected by this action.

2. Competence of Staff

Staff should be trained, and deemed competent work on the specific equipment that they will be undertaking preventative and corrective maintenance on, or have authorisation endorsed by their line manager. These will be recorded on your individual competency records.

Staff should have:

a) A current or be working towards an IRSE licence, where appropriate;
b) Certificates in safety activities, as appropriate (for example, PTS, SWL, COSS, Lookout, Working at Height etc);
c) Training in manual handling;
d) Knowledge of the Rule Book, particularly the Handbooks related to the Signalling activity they are undertaking.
e) Knowledge of HASAW, the Electricity at Work Regulations and COSHH.

3. Safety of Staff and Briefing Arrangements

Always carry out preventative/corrective maintenance using a safe system of work set up by the SWL (Safe Work Leader) or COSS (Controller of Site Safety).

Use a Safeguarded system whenever possible but other systems can be used as conditions permit.

Trackside briefing shall be given by the SWL/COSS before the work can start.

Site briefings, the nature of the work, any possible dangers, Rule Book protection etc. shall be recorded on a Company Site Assessment Briefing Sheet at the time of the briefing.

4. Communications and Emergency Plans

You should have a communication list for normal weekday working, weekend working, and on-call arrangements.

The list should include contacts for Network Rail, emergency services, hospitals and other contractors, as appropriate.

5. Protection Arrangements and Equipment

When working in a non-safeguarded area, as well as normal protection arrangements, for certain activities equipment will need to be disconnected or an alternative protective measure used. This is to prevent the signaller from accidentally using the equipment being worked on.

Points

When working on points, there are two risks that you need to protect against.

The signaller could accidentally set a route involving (calling) the points and so cause a risk of injury to the person working on the points.

The signaller may set a route with the points set in a particular position. If you then move the points to check or test them, you will disrupt the set route and this could cause a signal to revert to danger.

Before moving any points manually, request the Signaller to move them and then apply one of the protection options below and confirm the Signaller cannot obtain a proceed aspect over the affected points.

Protection options include the following:

a) Disable signal routes by dropping the track circuit that locks the points. Always confirm the effectiveness of this with the signaller by requesting them to attempt to move the points*

*The EP&RR function can allow signallers to move a set of points even when the track circuit locking the points is occupied, thereby rendering the protection afforded in a) ineffective.

Therefore the protection method defined in paragraph a) above is prohibited in Emergency Point and Route Release (EP&RR) areas. Technicians shall use an alternative method of protection as defined in b) to f) below.

b) For electronic interlockings, apply control(s) via the technicians' terminal to prevent the signaller from setting a route over the points. If the control(s) do not prevent the signaller from moving the points individually (e.g. SSI route bar) the points shall also additionally be switched to manual operation using the crank handle cut out or manual/auto switch.

c) Disconnect the point detection (KR lines) by consulting the wiring diagrams and slipping the appropriate links in the equipment room or apparatus case. The points shall also be switched to manual operation using the crank handle cut out or manual/auto switch.

d) Where all tail cables are connected to the point machine by plug coupler(s), disconnect all tail cable plug coupler(s) at the machine.

e) Place a competent person (as a reminder) with the signaller to oversee the Rule Book arrangements and remind the signaller of the work whenever necessary.

f) Apply a documented local operating arrangement that has been agreed with the Route Asset Manager (Signalling).

When working on points where bolt heads may need to be accessed or debris between the open switch rail and stock rail removed, it is good practice to scotch the open switch. This will prevent any unexpected movement that may be accidentally caused.

6. Railway and Public 'Interfaces'

Railway and public interfaces are areas where the public come into contact with signalling equipment

There are two main interfaces for preventative/corrective maintenance:

a) Level crossings
b) Equipment on platforms

No member of the public is to be put at risk.

7. Associated Hazards and Risks

These include:
a) The risk to staff from trains
b) Failure of signalling equipment.
c) Electrical injury
d) Accidents involving lifting, slipping, tripping, falling and trapping fingers.

Information is available in Hazard Directories, which will include red zone prohibited areas.

Information about dangers is also contained in local Health and Safety Policy Statements.

- Use official access points.

8. Tools and Plant

- See section NR/SMS/Part/A05 ‘Plant, tools and calibration’ for details.

9. Personal Protective Equipment

Personal Protective Equipment (PPE) shall be used at all times.

- Additional PPE may be required depending to the task to be carried out.
- Your SM(S) will supply the correct PPE for the situation and the circumstances that you will be working in.

10. Environmental Issues

- Follow the relevant company standards to dispose of waste material or scrap.

11. Working at Height

- Follow the relevant company standards when working at height.

End

General

Use the correct tools to carry out preventative and corrective maintenance.

When using a test or a measuring instrument (gauge, meter, insulation tester, and so on), it should be calibrated, within date and is fit for the purpose.

All calibrated instruments shall have a calibration label detailing the instruments unique ID and its next calibration date. If this label is not present, it is out of date, any seal is broken or the instrument is found to be faulty then the test will not be valid. You shall return faulty or un-calibrated equipment to your SM(S).

Details of test instruments and calibration requirements for S&T measuring equipment can be obtained via your SM(S).

If you are in any doubt about a gauge or test instrument, ask your SM(S) before use.

List of Approved Tools, Gauges and Test Instruments

The listing of these items is constantly changing with the removal of certain items and new items gaining product approval.

Any listing of these items in this section would be out of date in a short time and could lead to an incorrect item seemingly being approved.

Your SM(S) will be able to give you details of the currently available and approved items.

Plant

Typically includes:

- Bonding machine (powered)
- Drilling machine (powered)
- Disc cutters
- Angle grinders

This equipment shall be inspected and maintained and is identified by an inspection label.

Check before you use any the equipment that it is within the serviceable date.

End

1. General

1.1 Use the correct, approved materials when maintaining equipment.

1.2 Shelf life of materials should be considered, do not use items that are outside their service date or use before date. Inform your SM(S) if you come across any of these items.

1.3 If you are in any doubt about an item, ask your SM(S) before use.

2. Common Approved Materials

2.1 The listing of these items is constantly changing with the removal of certain items and new items gaining product approval.

2.2 Any listing of these items in this section would be out of date in a short time and could lead to an incorrect item seemingly being approved.

2.3 Your SM(S) will be able to give you details of the current available and approved items.

END

1. Security

1.1 Always check that access points to the railway are closed and secured at all times when they are not in use.

1.2 Equipment shall be secured against unauthorised access.

1.3 Refit and secure all locking devices, access doors, covers and plates before leaving the site.

1.4 Replace missing or ineffective locks.

2. Padlocks

2.1 Leave the padlock hanging vertically to reduce rain ingress to the key mechanism.

2.2 Do not put a padlock down on the ground when removed. Hang it on the lock staple or place it somewhere it will not get dirty.

3. Door Locks

3.1 If door locks are stiff or badly fitting, arrange for them to be repaired.

3.2 Do not remove or file out striker plates as this weakens the lock.

3.3 Lock mechanisms are not to be oiled as this attracts dirt. They should be lubricated with the correct type of graphite powder.

3.4 If keyhole cover plates are provided, confirm they drop when the key is removed. This keeps out dirt and insects.

4. Keys

4.1 Keys should be securely kept and not be labelled with their purpose; this greatly reduces the chances of misuse if they are lost.

4.2 After locking, check that the lock is effective by gently testing the door or tugging the padlock.

4.3 The following keys are in standard range:

a) JW 442 Grand Master for YS and YW locks for S&T personnel only.

b) JW 442 Sub-master YS for YW locks.

c) RKB 221 For S&T personnel only.

d) RKB 222 For Operating Dept. personnel only.

e) BR No.1 For Trainmen's access.

f) Triangular For wooden cupboards.

Many regional variations to the above list still exist. Special keys are required for some token and key release instruments and lifting barriers.

5. User Worked Crossings

5.1 Lower or close barriers or gates at user-worked crossings and report if you see any barriers or gates that have been left open or not lowered properly.

6. Lineside Fences

6.1 If you come across damaged or missing fencing, you should attempt to secure it if you can do this safely and report it to Control.

7. Extra Security

7.1 Your SM(S) will consider the need for extra security measures in the following circumstances:

a) Areas, which are being vandalised.

b) Places which the public use (such as stations, level crossings etc.).

7.2 Protection measures will be taken as appropriate. This could include:

a) Mesh cages.

b) Poly-carbonate signal lenses.

c) Anti-vandal guards.

d) Fencing.

e) Using lid fixing systems on cable troughs (bands, glue, channel rodding and so on).

f) Alarm systems.

g) Re-routing or burying cables.

h) Ladder Guards.

END

GENERAL

1. Renewals

1.1 Maintenance of Signalling equipment shall be planned at the required intervals using Ellipse. These intervals are set so equipment is maintained in a safe condition and remains fit for purpose.

1.2 Equipment may be maintained at different intervals depending on the regime being applied and this may alter from time to time with the application of the RBM initiative.

1.3 Give enough attention to equipment during each visit so it meets the required standard of maintenance.

1.4 As equipment ages, normal maintenance activities might not be able to maintain it to the necessary standard.

1.5 Similarly, equipment might be damaged or fail due to vandalism or interference by others.

1.6 When making repairs of a temporary or permanent nature, it is your responsibility to confirm that the equipment remains safe and reliable.

1.7 If it is not possible to maintain equipment to the necessary standard, or a temporary repair has been made, you shall report this on a WAIF to your SM(S). Identify the failed equipment and the reason for your request.

Your SM(S) is responsible for assessing each request, and prioritizing any action needed. Examples of problems are:

a) Wire Degradation.
b) Corroded Supports or Structures.
c) Rotten Bases or Boards.
d) Damaged Cable Routes.
e) Illegible or Missing Labels and Equipment Number Plates.
f) Equipment Seals or Gaskets.
g) Relay Bases.
h) Equipment Needing re-servicing.
i) Overgrowth or Infestation.
j) Worn Fittings.
k) Vandalism.
l) Silver migration.

END

GENERAL

1. Approved Lubricants

1.1 Only use approved lubricants on signalling equipment.

1.2 Dry film lubrication is the preferred lubricant type and should be considered for reduction of contamination and ease of inspection.

1.3 Dry film lubrication should also be supplemented at the maintenance frequency and the use of degreaser removed.

2. Teflon Dry Film Lubrication

2.1 Interflon Lube TF and Lube EP is a dry film lubricant that can be used to replace mineral oil, PTFE grease and Rocol.

2.2 Lube TF should be treated as a preparation light use lubricant including locks and hinges.

2.3 Lube EP should be the main maintenance lubricant for heavier use (standard for clamplocks).

2.4 Lubricant is suitable to replace grease in certain applications.

2.5 It is important to follow the manufacturer’s instructions, particularly those relating to preparing parts before applying the lubricant.

3. Mineral Oil

3.1 This is used for lubricating mechanical connections (unless grease points are provided) to reduce wear and make the connection work smoothly.

3.2 Apply oil sparingly and wipe away any excess or spillage.

3.3 Do not allow oil to come into contact with electrical equipment or wiring.

4. Lithium-Based Grease

4.1 This is generally used for greasing mechanical bearings (cranks, pivots, bushes, and so on) via grease nipples.

4.2 Remove excess grease to prevent the build-up of dirt. Teflon impregnated lithium grease (Grease MP1) is also available and is pumpable to very low temperature.

5. Adhesive-Type Grease

5.1 This is used to protect exposed mechanical parts (for example lock and detector slides) from the environment. Interflon Grease MP1 is suitable as adhesive grease.

6. PTFE Grease

6.1 Nulon QH90 grease contains Teflon and is suitable for use on clamp locks instead of Rocol. It is also suitable for use on other mechanical parts including cranks and slide chairs.

6.2 It is important to follow the manufacturer's instructions, particularly those relating to preparing parts before applying the grease.

7. Automatic Lubrication System

7.1 The Simalube (sliver/grey) automatic lubrication system can be used in various applications. Yellow end cap units are for use with Interflon liquid lubricants. Green end cap units are for use with Interflon grease.

7.2 Cartridges should be set to 12 months for standard application.

7.3 Reference should be made to the manufacturer's instructions relating to application and fitting.

8. Graphite Powder

8.1 Only to be used on locks and padlocks.

8.2 Avoid mineral oil, as it can allow dust/dirt to adhere inside the lock.

END

1. General

1.1 The painting of signalling equipment is part of maintenance but is usually managed outside of the normal maintenance scheduled tasks.

1.2 During each maintenance visit, make a note of any paintwork or surface treatments (for example galvanizing) that has deteriorated and report to the SM(S). The SM(S) will arrange for equipment to be repainted as necessary.

1.3 The following are examples of surface treatment faults that you should report:

a) Coatings that are cracked, peeling or flaking.

b) Rust, rust staining and blistering.

c) Vandalism and graffiti.

2. Points and Fittings

2.1 Cracks are often initiated from corrosion found around bolts holes and deterioration of galvanising is indicative of deterioration that might be worse on hidden surfaces.

2.2 During each maintenance visit, make a note of any galvanizing that has deteriorated and report to the SM(S). The SM(S) will arrange for equipment to be replaced.

2.3 Painting is not desirable as it can mask crack identification.

END

1. Technicians' Copies

1.1 Technicians' Copy diagrams are issued as an 'as installed' record of signalling systems and to support the testing and maintenance of the equipment.

1.2 It is essential that the diagrams are available, complete, accurate, and in a condition that is fit for use.

1.3 Store diagrams carefully, using the container provided. If any storage container is inadequate, inform your SM(S) so that they can arrange an alternative.

1.4 Diagrams are stamped, signed, and dated by the issuer. If this is not the case, assume the drawings are uncontrolled and ask for replacements.

2. Incorrect Drawings

2.1 Inform your SM(S) of any diagrams which are incorrect so that they can be updated, or replacement copies ordered.

3. Maintenance Work - Changes to Diagram

3.1 Maintenance work can result in a change to a diagram. Examples are:

a) Equipment replacement.

b) Cables renewals.

3.2 In such cases, you should inform your SM(S) so National Records Group can be informed for replacement diagrams.

3.3 Any temporary diversion of circuits is to be shown on the diagrams.

3.4 This is not a permanent change to the diagram and does not need reporting to Network Records Group.

3.5 Any necessary amendments shall be made in red ink and be signed and dated by the Technician.

END

1. GENERAL

1.1 The tasks and tests stated in this section are to be carried out on equipment after incidents of flooding.

1.2 Floodwater or rainwater ingress into equipment can cause tracking on electrical equipment, corrosion on mechanical equipment and contaminate hydraulic oils and lubricants. This can pose a risk to the safe and reliable operation of the equipment.

1.3 Flooding or moisture contamination does not have to be widespread or dramatic to cause serious problems.

1.4 Water is a very good conductor of electricity, therefore a small amount of moisture between terminals or on a printed circuit board can be sufficient to enable current to flow. This can result in a false feed, the shorting out of a vital circuit or provide an earth path.

1.5 Water on or inside metal equipment can lead to rust, lubricants becoming ineffective and equipment becoming seized.

1.6 Water and oil do not mix; any hydraulic oil affected can be made ineffective and lead to rusting inside the hydraulic system.

1.7 During each maintenance visit, check for signs of flooding or moisture contamination (rust streaks, ‘furring’ of terminals, silt deposits, ‘tide’ marks, etc).

1.8 Check gaskets, seals and glands are fitted correctly and show no signs of cracking, bulging or distortion.

1.9 Serious contamination shall require action and be reported to the Signaller and your SM(S).

1.10 If equipment is renewed, follow the SMTH.

1.11 Once debris (silt, twigs, rubbish etc.) has been removed from the equipment, you shall carry out the requirements in NR/SMS/PartB/Test 300 for each piece of affected equipment.

END

1. Waste Disposal

1.1 Waste is classed either as special waste or as non-special waste.

1.2 Keep special waste separate from non-special waste.

1.3 Some contractors will allow different types of special waste to be mixed if full COSHH details are sent.

1.4 You are only licensed to transfer waste from the worksite to your depots.

1.5 Your SM(S) shall provide waste disposal points and also arrange for a licensed contractor to take it away.

1.6 All waste shall be disposed of in accordance with current environmental policy. If in doubt, ask your SM(S).

1.7 Table 1 shows a typical arrangement of waste segregation.

Waste Type	Class	Disposal Point
Primary cells	Special	Depot battery box
Lead acid cells	Special	Depot battery box
Alkaline cells	Special	Depot battery box
Hydraulic fluid tins	Special	Special waste skip
Grease lubricant tins	Special	Special waste skip
Oil lubricant tins	Special	Special waste skip
Metal scrap	Non-special	Scrap metal skip
Plastic scrap	Non-special	Non-special skip
Cable and wire	Non-special	Designated area
Glass	Non-special	Non-special skip
Dirty cloth	Special	Special waste skip
Paper	Non-special	Recycling bin
Concrete	Non-special	Non-special skip
Asbestos cement	Special	Special waste skip
Treated wood	Special	Special waste skip
Wood	Non-special	Non-special skip
Paint tins	Special	Special waste skip
Cleaning agents	Special	Special waste skip
Herbicides and fungicides	Special	Special waste skip

Table 1 – Waste Disposal Classes

2. Recovered Signalling Equipment

2.1 Some signalling equipment can be repaired. Attach a non-conforming product label to it and take it to the depot quarantine area.

2.2 Signalling equipment that cannot be repaired is classed as scrap. You should put it in the appropriate skip.

3. Polychlorinated bi-phenols (PCB)

3.1 Some signalling equipment may contain PCBs. If it does, clearly labelled it.

3.2 If you have to replace the equipment, your SM(S) shall arrange for an approved disposal company to take it away from your depot.

3.3 Always check that you are putting the waste into the right skip.

END

1. General

1.1 Signalling assets can be taken out of use temporary (e.g., in conjunction with signalling or track renewal and enhancement work), permanently pending recovery, or 'moth balled' (e.g., closure of a branch line but assets left in situation with a possible re-instatement of the branch for a different purpose).

1.2 The time an asset can remain in this state can vary from a few days to years or possibly never.

1.3 Due to the asset being in this situation it is sometimes impossible to carry out the full NR/SMS tasks and tests in parts C and B.

1.4 This NR/SMS details the disconnection methods and the reduced tasks and tests.

1.5 In all cases it shall be checked by means of the diagrams and/or control tables that taking a signalling asset out of use does not affect any other signalling equipment that is to remain operational.

Out of Use Assets

1.6 All Out of Use Assets shall still be subject to Ellipse work orders which detail the maintenance requirement on the assets.

1.7 Your SM(S) will inform you of any additional signalling assets that require maintaining to this NR/SMS. If you are in any doubt if any asset is out of use or operational, ask your SM(S).

1.8 Signalling assets that are out of use shall be disconnected in such a way that it cannot be re-instated to service without a signalling Technician being involved in the process (e.g., physical disconnection of mechanical components or physical isolation of electrical circuits).

Assets controlled by electronic interlocking's such as SSI shall be disconnected at the Technicians terminal. Details of disconnections to assets can be found in section 1 to 10.

2. Form RT3187

A form RT3187 shall be issued for signalling assets that are taken out of use.

2.1 A copy of the form shall be kept in the controlling signal box of the asset. It shall be the responsibility of the signalling Technician to carry out the maintenance, to check that the RT3187 exists as authority to carry out this NR/SMS.

If the existence of the form cannot be verified, inform your SM(S).

3. Re-instatement

3.1 Signalling assets that are being maintained to this SMS, shall not be re-instated to full operational service without a method statement endorsed by the RAM(S).

3.2 The processes in SMTH shall be followed for the re-instatement of single or small numbers of simple assets.

For larger collections of assets where there is to be only a partial re-instated or there has been a change to the design of the layout, SWTH shall be followed.

If the asset has been out of use for more than three months, then a full annual service shall be carried out as part of the re-instatement process.

4. Maintenance

4.1 The reduced preventative maintenance for Out of Use Assets is detailed in sections 11 to 20. These tasks shall be carried out in place of the ones detailed in NR/SMS/Part/C.

DISCONNECTIONS REQUIRED TO RENDER AN ASSET OUT OF USE.

5. Points with No Trains Passing Over Them

Includes:	Points on lines that are completely out of use
Excludes:	Points that are used as trap points to a line that is in use or as flank protection for a line that is in use, use 'Points with Trains Passing Over Them'

If you are in any doubt about if the points fall into this category, ask your SM(S).

<u>Power Operated Points:</u>

5.1 Remove the motor and detection fuses; remove all links to the motor and detection circuits.

5.2 Check that reminder appliances are placed over the correct controls in the controlling signal box.

5.3 Power to any heaters can be maintained.

<u>Mechanically Operated Points:</u>

5.4 Remove (if provided) detection fuses and links to the detection circuit.

5.5 Remove the cotter pin to the catch handle on the point operating lever or (if provided) the FPL lever in the controlling signal box.

5.6 Check that reminder appliances are placed over the correct lever(s) in the controlling signal box.

6. Points with Trains Passing Over Them

6.1 The points shall be clamped, scotched and padlocked (or equivalent).

This is usually an operating responsibility to carry out but can be undertaken by signalling Technicians.

6.2 The points shall remain powered (power operated points) or connected (mechanically operated points) with working detection still proved in the interlocking.

More details on securing points out of use can be found in NR/GI/E054 (Securing Points Out of Use).

Power Operated Points:

Electronic Interlocking areas:

6.3 Apply the required controls via the Technicians' Terminal.

6.4 Check that reminder appliances are placed over the correct controls in the controlling signal box.

Relay Interlocking areas:

6.5 Remove the fuse/feed to the point NLR/RLR circuit (or point LR on E10k interlocking).

6.6 Check that reminder appliances are placed over the correct controls in the controlling signal box.

Mechanically Operated Points:

6.7 Place a reminder collar on the point lever and (if provided) the FPL lever.

7. Colour Light Signals which are Not Visible to Drivers

7.1 Where the loss of power to the signal does not affect the indications or aspects of any other signal that is visible to drivers, the signal and indications shall be totally powered down.

Where the loss of power to the signal does affect the indications or aspects of any other signal that might visible to drivers, remove the signal HR and DR links.

Check that reminder appliances are placed over the correct controls in the controlling signal box.

8. Colour Light Signals which are Visible to Drivers

8.1 Remove the signal HR and DR links.

Where it has been published in the weekly operating notice, a black cover with a white St. Andrews cross shall be placed over the signal aspects.

Check that reminder appliances are placed over the correct controls in the controlling signal box.

9. Semaphore Signals which are Not Visible to Drivers

9.1 Remove the signal arm and spectacle plate.

On electrically lit signals where the loss of power to signal does not affect any other signals that might be visible to drivers, the signal lamp, and indications shall be totally powered down.

On oil lit signals, remove the oil lamp. If the signal illumination is indicated in the controlling signal box, power down the indication.

Check that reminder appliances are placed over the correct controls in the controlling signal box.

10. Semaphore Signals which are Visible to Drivers

10.1 Where it has been published in the weekly operating notice, remove the signal arm and spectacle plate, if this is not practical a white St. Andrews cross shall be attached to the front of the arm.

On electrically lit signals where the loss of power to signal does not affect any other signals that might be visible to drivers, the signal lamp, and indications can be totally powered down.

On oil lit signals, remove the oil lamp. If the signal illumination is indicated in the controlling signal box, power down the indication.

Check that reminder appliances are placed over the correct controls in the controlling signal box.

Lamp proving of semaphore signals is often grouped, so that removing one lamp results in the group indicator showing lamp out.

10.2 The lamp proving for the removed lamp might need to be strapped out, this shall only be done once diagrams and method statements have been prepared and approved in accordance with the SMTH.

11. Track Circuits

11.1 Track circuits shall be powered down by removal of the supply fuses or disconnection of the primary cells, providing this does not affect any other signalling equipment that is still operational.

If requested by the Signaller, the indications on the panel might be extinguished along with a legend stating the track circuit is out of use.

12. Level Crossings

Level crossings with gates:

12.1 Gates shall be secured (by means of a chain and padlock or similar) in the closed to rail traffic position.

12.2 Electric gate lights shall be powered down and oil gate lights shall be removed. The road lights (wig-wags) if provided shall be powered down by removal of the supply fuses.

12.3 Check that reminder appliances are placed over the correct controls in the controlling signal box.

Level crossings with booms:

12.4 The road lights (wig-wags) and boom lights shall be powered down by removal of the supply fuses.

12.5 Booms shall be secured in the raised position.

If this is not practical or possible, the booms shall be removed, and the side arm assembles/counter weights secured or removed.

12.6 Check that reminder appliances are placed over the correct controls in the controlling signal box.

13. Ground Frames

Electrical Ground Frames:

13.1 The points shall be dealt with as detailed in the points section of this SMS.

13.2 The switch panel shall be powered down by removal of the supply fuses.

13.3 Check that reminder appliances are placed over the correct controls in the controlling signal box.

<u>Mechanical Ground Frames:</u>

13.4 The points shall be dealt with as detailed in the points section of this SMS.

13.5 The power supply to the release lever lock shall be isolated either at the ground frame or monitoring signal box.

13.6 Check that reminder appliances are placed over the correct controls in the controlling signal box.

14. Trackside Apparatus Cases (Location) and Equipment Rooms

14.1 Where the location or equipment room controls assets that are out of use, it can be powered down by removal of the incoming supply fuses.

14.2 The location or equipment room shall be suitably secured. In vandal prone areas the padlocks can be replaced with a bolt and self-locking nut.

PREVENTATIVE MAINTENANCE TO OUT OF USE ASSETS

15. Points with No Trains Passing Over Them

Includes:	Points on lines that are completely out of use.
Excludes:	Points that are used as trap points to a line that is in use or as flank protection for a line that is in use, use ‘Points with Trains Passing Over Them’

SERVICE A

15.1 Check or verify that a RT/3187 form is available.

15.2 Visually check the points for security of fittings and evidence of vandalism.

Report any degradation to your SM(S).

15.3 Check or verify that the correct reminder appliances are in place in the controlling signal box.

16. Points with Trains Passing Over Them

SERVICE A

16.1 Check or verify that a RT/3187 form is available.

16.2 Report any degradation or evidence of vandalism to your SM(S).

16.3 Check that the points are suitably clamped and scotched.

16.4 Visually check the points for security of the stretcher bars (including the lock stretcher where provided), and associated fittings.

16.5 Check that the FPL is still holding the lock blades or lock stretcher or that the drive lock slide on RCPLs is still fully through the Lock Body Unit. Rectify as necessary.

16.6 Check that the free wheel clearance and the residual switch opening are being correctly maintained. Details of values are in NR/SMS/PartZ/Z02 (Point Reference Values).

16.7 If provided, check that the point machine is secure, and the lid is correctly fitted and padlocked.

16.8 If provided, check that the point rodding and cranks are secure.

16.9 Check or verify that the correct reminder appliances are in place in the controlling signal box.

SERVICE B

These tests shall only be carried out if the points can be unclipped and un-scotched:

16.10 Identify and carry out the correct Facing Point Lock Test for the equipment being serviced NR/SMS/PartB/Test 011 to 013.

16.11 Identify and carry out the correct Detection Test for the equipment being serviced NR/SMS/PartB/Test 011 to 013).

.

Power Operated Points:

16.12 If 12.10 is not possible, remove the cover/lid and break each detection contact in turn.

16.13 Check that the relevant detection relay de-energizes with each break.

This check is not be possible on clamp lock and HPSS systems.

Mechanical Points with Electrical Detection:

16.14 If 12.10 is not possible, remove the cover/lid from the electrical detector and break the detection contact in turn.

16.15 Check that the relevant detection relay de-energises with each break.

This might not be possible on all types of electrical detector.

Mechanical Points with Mechanical Detection:

16.16 If 12.10 is not possible, check that the signal reading over the points (if still operational) is mechanically held at danger by the detector.

17. Colour Light Signals which are Not Visible to Drivers

SERVICE A

17.1 Check or verify that a RT/3187 form is available.

17.2 Visually check the signal for security and evidence of vandalism. Report any degradation to your SM(S).

17.3 Cables suspended from the structures above overhead line equipment that are out of use shall be inspected.

17.4 Check or verify that the correct reminder appliances are in place in the controlling signal box.

18. Colour Light Signals which are Visible to Drivers

SERVICE A

18.1 Check or verify that a RT/3187 form is available.

18.2 Visually check the signal for security and evidence of vandalism. Report any degradation to your SM(S).

18.3 If the signal has not been powered down check that it is displaying a red aspect, or if a cover has been fitted over the lenses, it is in place and secure.

18.4 Cables suspended from the structures above overhead line equipment that are out of use shall be inspected.

18.5 Check or verify that the correct reminder appliances are in place in the controlling signal box.

SERVICE B

18.6 If requested by your SM(S) replace the red aspect lamp.

18.7 Carry out NR/SMS/PartB/Test/021 (Filament Signal Lamp Tests) on the red aspect lamp.

19. Semaphore Signals which are Not Visible to Drivers

SERVICE A

19.1 Check or verify that a RT/3187 form is available.

19.2 Visually check the signal for security and evidence of vandalism. Report any degradation to your SM(S).

19.3 Cables suspended from the structures above overhead line equipment that are out of use shall be inspected.

19.4 Check or verify that the correct reminder appliances are in place in the controlling signal box.

20. Semaphore Signals which are Visible to Drivers

SERVICE A

20.1 Check or verify that a RT/3187 form is available.

20.2 Visually check the signal for security and evidence of vandalism. Report any degradation to your SM(S).

20.3 Cables suspended from the structures above overhead line equipment that are out of use shall be inspected.

20.4 If the lamp has not been powered down or the oil lamp has not been removed check that it illuminated. If a St. Andrews cross has been fitted over the arm, check that it is correctly in place and secure.

20.5 Check or verify that the correct reminder appliances are in place in the controlling signal box.

SERVICE B

20.6 If electrically lit and if requested to by your SM(S) replace the lamp.

20.7 If electrically lit, carry out NR/SMS/PartB/Test/021 (Filament Signal Lamp Tests).

21. Track Circuits

SERVICE A

21.1 Check or verify that a RT/3187 form is available.

22. Level Crossings

SERVICE A

Level crossings with gates

22.1 Check or verify that a RT/3187 form is available.

22.2 Visually check the gates and (if provided) road lights for security and evidence of vandalism. Report any degradation to your SM(S).

22.3 Check that the gates are securely locked closed to rail traffic.

22.4 Check or verify that the correct reminder appliances are in place in the controlling signal box.

Level crossings with booms

22.5 Check or verify that a RT/3187 form is available.

22.6 Visually check the crossing infrastructure for security and evidence of vandalism. Report any degradation to your SM(S).

22.7 If the booms are still fitted, check that they are secured in the raised position.

22.8 Check or verify that the correct reminder appliances are in place in the controlling signal box.

23. Ground Frames (Electrical and Mechanical)

SERVICE A

The points shall be dealt with as detailed in the points section of this SMS.

23.1 Check or verify that a RT/3187 form is available.

23.2 Visually check the ground frame infrastructure for security and evidence of vandalism. Report any degradation to your SM(S).

23.3 Check or verify that the correct reminder appliances are in place in the controlling signal box.

24. Trackside Apparatus Cases (Location) and Equipment Rooms

SERVICE A

24.1 Visually check the location or equipment room for security and evidence of vandalism. Report any degradation to your SM(S).

END

1. General

1.1 There are many signal engineering documents that contain detailed and useful information about specific assets. Some of these are listed at the beginning of the relevant NR/SMS tasks and tests. This section lists the documents that may be useful for reference purposes.

1.2 They are available on Connect via the 'NR Standards' link and using the search function to call up the document number. Externally they are available through uk.ihs.com.

1.3 Once a document is downloaded or printed from its electronic source, it is to be considered as uncontrolled.

1.4 The status of these documents can change during the life of this SMS; always check the status of the document on the NR Standards site or uk.ihs.com before use.

General

A glossary of general Signalling terms is given in GK/GN0802. Those terms are not repeated here except where they have been given a more technical definition for use within this document.

Any reference to source indicates that the definition has been taken from an external document.

Glossary of Signalling Terms

Term	Meaning
Adequate sighting	Check that the driver's view of a signal is not obstructed, e.g. by trees, bushes, buildings or other structures, and can be seen for the required reading time on approach (see NR/L2/SIG/10157). Alignment is detailed in NR/SMS/SG00.
Affected lever/locking	Any locking affected by the removal or potential release of any part which could alter the setting or integrity of the locking.
Alterations	Changes to existing installations (including the provision of new Signalling) which form part or all of a self-contained scheme. A single alteration is by definition one which is designed to be commissioned on a single occasion.
Apparatus	A product with an intrinsic function intended for the end-user and supplied or taken into service as a single commercial unit. [source: EMC Regs - modified]
Apparatus case	An apparatus housing which is intended for unprotected outdoor use, is smaller than a building or REB and is usually capable of being transported as a made-up unit. It is usually of metallic construction. The wooden equivalent is commonly known as an apparatus cupboard
Apparatus housing	This is provided to house relays and / or other equipment at lineside locations or interlocking's, and may consist of an apparatus case, apparatus cupboard disconnection box, equipment room, REB, signal box, control center, or other equipment building.
Application criteria	Document(s) specifying the constraints applied to the installation and maintenance of a system or an item of equipment in order that if can be guaranteed to deliver the performance attributes stated in the system or equipment specification.
Approval	The status given by the requisite authority when the product or works complies in all respects with the specification and addresses all identified risks.
Aspect test	See signal aspect test.
Assessment	The undertaking of an investigation in order to arrive at a judgement based on evidence, of the suitability of a product, competence of a person or acceptability of a risk. (source: BS EN 50126 expanded)
Authorisation	The formal permission to use a product within specified application constraints. (source: BS EN 50126)
Automatic function	A Signalling function that, under ordinary operation, is operated automatically by the passage of trains and is not interlocked with any other Signalling function. The function is generally associated with a particular signal box from which its operation is supervised, unless some form of local monitoring is provided. The state of the function when there are no trains present is designated normal.
Back (B) contact	A contact of a relay which is made when the relay is released and broken when it is operated.

Term	Meaning
Back feed	An inadvertent feed which has arisen at an intermediate point within a circuit due to the uncontrolled combination of positions of several piece s of control equipment.
Balise	A track mounted spot transmission unit that uses magnetic transponder technology. Its function is to transmit/receive messages to/from the train passing overhead. A TASS balise is passive with no interface to a Lineside Electronic Unit (LEU) and will therefore only transmit the fixed telegram stored in its memory. This data can only be changed by reconfiguration.
Balise Positioning Form (BPF)	Provides all the necessary information to the installer to allow the accurate trackside positioning and installation of the balise.
Balise Testing Form (BTF)	Provided to allow appropriate checks and tests associated with the balise to be recorded and a record retained.
Block tests (various)	A test to ensure correct operation of specified block equipment.
Bonding plan	A detailed plan of the track layout showing individual rails and position of IRJs, together with track circuit feed and relay connections with polarities, cross bonds, structure bonds, impedance bonds, etc., as applicable. This term may also include track plans and negative Bonding Plans in D.C. electrified areas.
Cable function test	A test to ensure that each circuit in a cable functions correctly after work on that cable.
Change-over contact	See dependent contact
Circuit diagrams	A collection of individual drawings showing the equipment layout and circuit arrangement associated with a location, an interlocking or signal box.
Circuit function test	A test of each individual circuit to verify the presence of the necessary controls.
Class I equipment	Electrical equipment that requires the connection of the exposed- conductive-parts to a protective conductor connected to earth, to ensure personal safety. See BS 2754.
Class II equipment	Electrical equipment with double or reinforced insulation, either to prevent contact with exposed-conductive-parts, or to ensure no contact between such parts and live parts. The insulation is not therefore to be pierced by screws. Such equipment is never connected to earth. See BS 2754.
Closure list	Final Index of design details issued to the tester in charge.
Common cause failure (CCF)	A failure which is the result of an event(s) which, because of dependencies, causes a coincidence of failure states of components in two or more separate channels of a redundancy system, leading to the defined system failing to perform its intended function. (source: BS EN 61508)
Competent person	A person who has the appropriate competence, authority to work, experience and ability to perform a particular task.
Concentrator	A facility to connect several telephone circuits to one terminal and thus avoid the need for a telephone instrument for each circuit.
Configuration control	A procedure to ensure that the functional and physical characteristics of a design or product are adequately identified and that changes to these characteristics are controlled and traceable throughout the life-cycle of the design or product, by recording its version or modification state. Also known as version control.

Term	Meaning
Configuration (system)	The structuring and interconnection of the hardware and software of a system.
Construction	The carrying out of any building, civil engineering or other engineering work, particularly that which falls within the scope of the Construction (Design and Management) Regulations 1994. Also known as installation.
Continuity test	A test to ensure the continuity and correspondence of each individual wire or cable core shown on the wiring diagrams.
Control point	A signal box (including control center), gate box or ground frame (including ground switch panel or shunting frame).
Control table test	A test to ensure that each Signalling function conforms to all the requirements specified in the approved Control Tables. This test applies to Signalling works testing.
Controlled function	A Signalling function that, under ordinary operation, is controlled from the signal box (or other control point) to which the function is allocated and may be interlocked with other Signalling functions.
Correlation	The comparison of the configuration and version status of a system with the design records to ensure that the two are in agreement.
Correspondence	Ensuring that the following all agree: 1 The controlling device, e.g. relay or SSI telegram, AND The operated function, AND 3 The associated signal box indication(s), e.g. repeat relay or SSI telegram.
Custodian (of records)	The organization appointed by the infrastructure owner to take care of master records. Also known as records custodian.
Cut-section (track circuit)	A method of reducing the continuous length of a track circuit by the use of individual track circuits, each one controlling a common final track repeat relay, or equivalent. These are indicated as one track circuit on the Signaller’s panel. This is also known as a multi-section track circuit.
Data (Signalling)	Site specific geographical and control information in an electronic form, which may be of a safety-critical nature or otherwise. In order to be used in an electronic system or sub-system, data from master data files is usually permanently stored in an EPROM (erasable programmable read only memory).
Data link	A serial data transmission system. In SSI systems, this refers to the link between the interlocking and the lineside location and may take the form of a baseband unmodulated trackside data link cable, or a long line link using standard telecommunications PCM equipment. Internal data link cables are also provided between the modules in an SSI cubicle and, where applicable, between modules in adjacent interlocking cubicles.
De-energised (relay)	See released.
Degraded conditions	The state of the part of the railway system when it continues to operate in a restricted manner due to the failure of one or more components.
Dependent contact	A contact set which consists of a front contact, a back contact and one arm shared between them, with not more than one contact path made at any one time. Also referred to as change-over contact.
Design	A wide term including specification and the production of drawings, design details and bills of quantity (including specification of systems or equipment). (source: CDM Regulations - modified)

Term	Meaning
Design authority	Network Rail or such other organization as is contracted by Network Rail to undertake specified design work on a system or on the infrastructure.
Design details (Signalling)	Any plans, control tables, engineering details and data, which are required to sufficiently define Signalling systems and equipment for production or record purposes.
Design records	Design details defining the current state of the infrastructure.
Destructive test	A test which may alter the electrical, mechanical or physical state of the equipment.
Difference list	A computer / data processor generated print out (produced by a validated software program) which details the data differences between two versions of a software program or data.
Disarrangement of interlocking	The interlocking can no longer be relied on to operate safely because of the removal or disturbance of component parts.
Disconnection box	An apparatus housing for unprotected outdoor use, which is intended to contain mainly terminations and is commonly smaller than an apparatus case.
Dog chart comparison test	A test to ensure that the mechanical locking agrees with the site drawings.
Double-cut (circuit)	The inclusion of controls in both feed and return legs in order to mitigate the risk associated with a false feed or earth fault.
Drop away (DA) voltage (relay)	The maximum voltage applied to an operated relay coil at which the last front contact breaks.
Drop shunt	The maximum value of non-inductive resistance which, when placed across the rails, causes the track relay to fully open its front contact.
Drop-away time (track circuit)	The time between the application of a shunt to the rails and the front contacts of track relay (TR) fully opening. The converse is pick-up time.
Earth fault	Unintentional contact between a circuit conductor and a conductive part at earth potential, by which an earth fault current may flow.
Earth fault detector	A permanent device, wired to the busbars, that will detect an earth fault on the power supply and give an alarm that will alert the maintainer. Also known as earth leakage detector.
Earth fault loop impedance	The impedance of the earth fault current loop starting and ending at the point of earth fault. (source: BS 7671 extract)
Earth leakage detector	See earth fault detector.
Earth test	A test to ensure that leakage current to earth is below specified limits.
Emergency situation	A current unforeseen or unplanned event which has life threatening or extreme loss implications and requires immediate attention (e.g. a fire).
Energised	See operated.
Engineering details (Signalling)	Design details from which a Signalling system is constructed.
Engineers Line Reference (ELR)	A unique alphanumeric code used by Network Rail to define each route segment of the network.
Equipotential bonding	Electrical connection maintaining various exposed-conductive-parts and extraneous-conductive-parts at substantially the same potential. It need not include a direct connection to earth. (source: BS 7671 augmented)

Term	Meaning
External (circuit or power supply)	Failing to wholly meet the internal criteria.
Extraneous lighting	An external light source affecting a signal aspect, e.g. from an open signal head door or nearby streetlamps.
Fail-safe	A concept which is incorporated into the design of a product such that in the event of failure, it enters or remains in a safe state. (source: BS EN 50129)
Final functional test	A test carried out immediately prior to "signing-in" for operational use to ensure all equipment is fully connected and operates correctly.
FREDDY	Flange Reading Electronic Detector Designed at York. FREDDY treadles are not approved for use on Network Rail Infrastructure and will be removed in due course.
Free-wired interlocking	A relay interlocking that comprises individually wired relays rather than pre-wired sets of relays.
Frequency division multiplex (FDM)	A data transmission system that uses unique frequencies to separate channels over a single pair of conductors. See NR/SMS/SB00
Front (F) contact	A contact which is made when the relay is operated and broken when it is released.
Functional earthing	The connection to earth necessary for the proper functioning of electrical equipment, i.e. an earth return. This may be used for telecommunications purposes but is no longer permitted for new Signalling circuits. Conductors for functional earthing are identified by the colour cream. (source: BS 7671 augmented)
Global Positioning System (GPS)	A non-railway system used to determine geographical vicinity.
Graceful degradation	A means by which a more complex control sub-system has the facility to switch into some other (more restricted) mode of operation if a particular input fails, or if availability is otherwise reduced by some means.
Guaranteed power supply	See secure power supply.
Independent checking	Independent checking means that one person undertakes the work and another person checks it. In some cases, testing may be started before the work is completed. In other cases, the work may allow two staff to work on two tasks and then change over to test each other's work (as long as both are Maintenance Testers). Maintenance Testing may often be quite interactive within the guidelines of independence.
Inspection	A visual check to ensure that the specified equipment has been installed securely, undamaged and in accordance with the design details.
Installation (infrastructure)	That part of the Signalling system associated with the infrastructure at a particular place.
Insulated rail joint (IRJ)	A method of joining rail ends together whilst maintaining electrical insulation between them. An alternative non-preferred term is insulated block joint (IBJ).
Insulation test	A test to ensure that a cable, wire, spare core or other equipment meets the required insulation criteria.
Interlocking (building)	The (generally dedicated) building housing the interlocking system, where separate from the signal box (or other control point).

Term	Meaning
Interlocking (equipment)	The equipment that performs the role required of the interlocking system.
Interlocking (system)	The safety-critical locking provided between Signalling functions in accordance with control tables.
Interlocking area	The area of railway controlled by a particular interlocking, extended up to a boundary with each other adjacent interlocking controlled by the same or another signal box.
Internal (circuit)	A circuit that does not leave the apparatus housing in which it originates, and which is fed from a busbar which feeds only internal circuits. This includes the feed to an isolated transformer supplying an external circuit. Circuits that extend between adjacent apparatus housings may be considered to be internal if they are run in a protective non-conducting duct and are judged to be away from any environment that might be susceptible to earth faults.
Internal (power supply)	A power supply feeding only internal circuits. Also known as local power supply
Joint hopping	Where fast moving short vehicles pass from one track circuit to the next, the difference between the pick-up and drop-away times can cause the vehicle to momentarily be undetected.
Jumper	An interconnecting cable (commonly single core) between two termination points within an apparatus housing.
Jumper cable (track circuit / traction)	An interconnecting cable (commonly single core) between two pieces of rail that are not adjacent, for track circuit or traction purposes. This includes midpoint connections to impedance bonds.
Lamp proving relay	A neutral DC. relay designed to operate from the current supplied to signal lamps and to release when lamp or lamps burn out. Some relays incorporate a bridge rectifier to operate from a.c. lamp currents.
Left hand relay	The left-hand half of a twin relay as viewed from the front. In a 930 series twin relay this controls the contacts in banks C and D.
Like-for-like replacement	The removal and restoration of an item of equipment, including a cable, in a previously working and commissioned system where the work does not change the design. This may involve restoring the original item of equipment or replacing it with an operationally equivalent new item.
Line circuit	An external relay circuit, which is not a trackside circuit.
Local panel	A panel (sometimes simplified) provided at the interlocking and capable of being used to take over control from the main panel at the signal box. It may also be used as a maintainer's monitoring panel, when the operating function is not in use.
Local power supply	See internal power supply.
Main cable	A twin or multicore lineside cable carrying Signalling functions or power supplies between apparatus housings.
Main earthing terminal (MET)	The terminal or bar provided for the connection of protective conductors, including equipotential bonding conductors, and conductors for functional earthing if any, to the means of earthing. (source: BS 7671)
Maintainer's monitoring panel	An indication panel situated at the interlocking that repeats the indications sent to the Signaller and allows the maintainer to observe the state of the interlocking. It also indicates various fault conditions. This may be combined with a test panel.

Term	**Meaning**
Maintainer's terminal	This consists of a VDU, keyboard and printer connected to a solid state interlocking, or an IECC system monitor sub-system. It is used to obtain essential fault diagnostic information and also acts as an interface with the system to enable restrictive controls on the equipment to be set. Also known as a Technician's Terminal.
Maintenance	The combination of all technical and administrative actions, including supervision actions, intended to retain a product in, or restore it to, a state in which it can perform a required function. (source: BS EN 50126)
Maintenance records	Design records kept on site for maintenance purposes.
Maintenance tester	A person certificated as competent in the application of Maintenance Testing.
Master record	The certified Signalling design record from which duplicates are obtained for issue. See also source record.
Mechanical locking function test	A test to ensure that each mechanical lever is locked in its correct position.
Mentor	A person appointed as guide and council to a Trainee in a specific competence. The Mentor retains responsibility for the Trainee's actions in the Mentored Competence, but the Trainee is able to gain the necessary experience under field conditions. The Mentor ensures the safety and integrity of the Signalling system.
Meshed circuit	Complex circuitry feeding more than one relay, where the same could be achieved by independent circuits, thereby requiring duplication of contacts. Not all paths in a meshed circuit are applicable to all relays.
Method statement	A comprehensive step-by-step plan of how the work is to be safely carried out in order to ensure that all hazards are considered and risks minimised.
Missing equipment	Equipment which was previously working, and which is physically missing or separated from its normal position.
Mod state	See modification status.
Modification status	The detail that defines the particular version of the design or specification, appropriate to the functional and physical characteristics of an item of equipment or system, and is recorded under configuration control procedures. Colloquially known as mod state.
Modifications	Changes to the design details which are required to be carried out after they have been officially issued, usually as a result of installation, testing and commissioning activities.
Monitored (level crossing)	Checked by the observation of indications which provide the Signaller with the status of equipment.
Non-conceptual work	Work which is based directly on an applicable existing proven design and does not introduce new design features to a system. This includes work items that facilitate maintenance, or performance improvements, whilst maintaining similar functionality. Testing of this shall be undertaken to NR/L2/SIG/30014/G110
Non-destructive test	A test which may involve: visually examining Signalling equipment, taking measurements or readings without disconnecting the equipment or disturbing the electrical characteristics of the system.

Term	Meaning
Non-safety- contact	A relay contact that is not a safety contact. This includes metal to metal contacts for medium duty use, where both elements are made of silver, silver cadmium oxide, or 60/40 silver palladium.
Non-safety- related	A Signalling function or sub-system where operational safety and the integrity of the interlocking are not directly affected. Manual intervention, where a failure would be noticed, may be part of the process. Formerly known also as non-vital.
Non-vital	See non-safety-related.
Normal (function)	Position of a lever when it is fully back in the lever frame (away from the operator). The non-operated or quiescent state of a two-state system. The converse is reverse.
Note (failure investigation records)	Clearly record the facts when they are reported or discovered. Notes shall be readable and retained for future reference.
Operate time (relay)	The time interval between the energisation of the relay coil and the first front contact making. The converse is release time.
Operate voltage (relay)	The minimum voltage applied to a released relay coil at which the last front contact makes. Also known as pick-up (pu) voltage.
Operated (relay)	The state of a relay when the armature is energised, picked up (PU), or latched, all front contacts are made, and all back contacts are broken. Also known as energised, and colloquially as ‘picked’ or ‘up’. The converse is Released.
Operationally equivalent	The replacement item of equipment is functionally identical to the item it replaces.
Out of use	Non-operational equipment that is still connected to the infrastructure. See also spare.
Output	This includes all relevant indications, displays, communications links, power drives, etc.
Pick-up (PU) shunt	The minimum value of resistance between the two running rails at which the track relay just closes its front contacts.
Pick-up (PU) voltage (relay)	See operate voltage.
Pick-up time (track circuit)	The time between the removal of a shunt to the rails and the first front contact of the track relay (TR) making. The converse is drop-away time.
Pin-code	See registration pin-code.
Plugboard	The permanent mounting block and termination for external wiring, for use with plug-in equipment.
Plug-in	The attribute of an item of electrical equipment which can be replaced without disconnecting any wiring.
Point detection & correspondence test	A test to ensure the required correspondence between points and their controls and indications is achieved and ensure detection contacts are effective.
Polarised circuit	A circuit where the resulting operation is dependent on the polarity or phase angle of the feed.
Primary function relay	The relay by which the logic required to control a Signalling function is brought together. It is the first relay in a chain that directly controls all safety critical Signalling functions. it is the only function relay which has back contacts valid for use in safety-critical functions.

Term	Meaning
Principles test	A test to ensure that the Signalling system provided conforms to Railway Group Standards and Statutory Requirements and is fit for purpose. This test applies to Signalling works testing.
Product acceptance	Authorisation for the use of a product type. undertaken by the product acceptance team
Public emergency telephone system (PETS)	A special telephone system for use at level crossings, which includes provision for proving that handset connections are intact and also for the transmission of level crossing status indications. The speech path has priority over other facilities.
Pulse code modulation (PCM)	A serial data transmission system by which many channels of information are passed over a data link, by use of a multiplexer.
Random hardware failure	Failures occurring at random times, which result from a variety of degraded mechanism in the hardware. Note 1) There are many degradation mechanisms occurring at different rates in different components and since manufacturing tolerances cause components to fail due to these mechanisms after different times in operation, failures of a total equipment comprising many components occur at predictable rates but at unpredictable (i.e. random) times. Note 2) A major distinguishing feature between random hardware failures and systematic failures is that system failure rates (or other appropriate measure), arising from random hardware failures, can be predicted with reasonable accuracy but systematic failures, by their very nature cannot be accurately predicted. That is, system failure rates arising from random hardware failures can be quantified with reasonable accuracy but those arising from systematic failures cannot be accurately quantified. (source: BS EN 61508)
Record	Information bearing media, irrespective of date or physical format, created or received in the course of carrying out the duties and functions of an undertaking, and subsequently retained by the undertaking or its successors as evidence, as a reference source, or to meet legal or regulatory obligations.
Records custodian	See custodian (of records).
Registration pin-code	A series of locating pins assembled in a unique pattern to prevent equipment being incorrectly used. The unique pattern also acts as a means of identification for a specific style and variant of a relay. The term registration pin-code is commonly abbreviated to pin-code.
Release time (relay)	The time interval between the removal of the supply (at rated voltage) to the relay coil and the last front contact breaking. The converse is operate time.
Released (relay)	The state of a relay when the armature is de-energised, dropped away (DA), or unlatched, all back contacts are made and all front contacts are broken. Also known as de-energised and colloquially as ‘dropped’ or ‘down’. The converse is operated.
Relocatable equipment building (REB)	Apparatus housing to specification BR 1615 or equivalent. Also known as PER (portable equipment room)

Term	Meaning
Reset	Placing a system into a state which corresponds with the actual state of the railway prior to restoration into service, fault finding or testing. For an axle counter, this is the action of setting the number of axles registered in a track section to zero.
Residual voltage	The voltage remaining across the rails or relay of a track circuit after the feed has been disconnected. It may be caused by mutual interference between adjacent single rail track circuits, the battery effect of the track formation, cathodic protection measures, or d.c. traction return or other stray currents.
Restoration	Accepting reset systems back into service by the Signaller after maintenance, failure or (for axle counters) miscount.
Reverse (function)	Position of a lever when it is fully out of the lever frame (towards the operator). The operated state of a two-state system. The converse is normal.
Right hand relay	The right-hand half of a twin relay as viewed from the front. In a 930 series twin relay this controls the contacts in banks A and B.
Risk Based maintenance	A maintenance system developed failure mode studies, deterioration analysis, and consequence assessments, to allow differing maintenance intervals depending on the risk classification of the asset. This maintenance system shall **not** now be used on Network Rail
Reliability Centered Maintenance	Also known as RoSE (Reliability Centered Maintenance on Signalling Equipment). A maintenance system using an analysis of the equipment location, use, and failure modes to provide a full maintenance regime Shall only be used when authorized
Safe state	Any one of the following: the state of the last valid request at the interlocking; or correspondence with the state of the trackside equipment; or the most restrictive state.
Safety contact	A relay contact that is specified for safety purposes in the 930 series specifications. These are non-weld contacts, generally silver to carbon for ordinary use. For medium duty use, the contact elements may be of silver impregnated graphite (SIG) and silver.
Safety-critical	Carries direct responsibility for safety. (source: BS EN 50129)
Safety-related	Carries responsibility for safety (direct or indirect). (source: BS EN 50129)
Secure power supply	A power supply system that can be relied upon to keep certain safety- critical Signalling functions operating for a predetermined minimum time, in the event of a total failure of the main incoming supply. Also known as guaranteed power supply.
Signal aspect test	A test to ensure that only the correct aspects and indications as specified in the approved control tables and signal aspect sequence charts are displayed to the driver.
Signal sighting form	A form that depicts the profile, location and other details of each signal as agreed by the signal sighting committee.

Term	Meaning
Signalling function	Final discrete component of a Signalling system listed on control tables with a unique identity (such as signals, points, train detection devices, releases and level crossing barriers) and the circuitry or logic by which it is controlled an/or proved. Signalling functions are allocated (as defined by the control tables) to a specific interlocking controlled by a particular signal box (or other control point) and are given a unique identity within a particular Signaller's area.
Signalling system	Equipment, circuitry and software associated with: Lineside signals; Point operation; Level crossings; Train detection; Trainborne equipment conveying information about the state of the line; operational telecommunications (excluding electrification control systems and electrification telephones); and fixed trackside safety systems.
Single cut (circuit)	The inclusion of controls in either the feed or return leg, but not both. (See double cut.)
Slow acting relay	A relay in which both operation and release are intentionally delayed.
Slow to operate relay	A relay in which the operation is intentionally delayed and the operate time is significantly longer than the release time.
Slow to release relay	A relay in which the release is intentionally delayed, and the release time is significantly longer than the operate time.
Software controlled system (SCS)	Any item of electronic equipment which is controlled by software to enable it to perform the required activities. Examples include general purpose microprocessor systems (e.g. proprietary Personal Computers), dedicated systems using microprocessors or Digital Signal Processors. Note that a SCS may be composed of separate items, which are referred to in this document as "the parts of the SCS". Note: Application Specific Integrated Circuits (ASICs) have similar characteristics to software; for example, they are not readily visible to the tester, they may be created by software-controlled machines, and they may themselves require configuration by data. Therefore, the term SCS shall be taken to include ASICs, and consideration shall be given to applying these requirements to machines which contain no software but do contain ASICs.
SPAD	Signal Passed at Danger. The term used to describe an incident when a train has passed a stop signal at danger without authority. SPADs are categorised are detailed in GO/RT3119
Spare	Equipment not connected to any part of the infrastructure. See also out of use.
Specialist investigation	Examination or monitoring by a competent, independent Signalling and telecommunications specialist capable of undertaking comprehensive technical investigation of equipment and systems, where necessary using complex instrumentation.
Stagger (electrical)	The phase or polarity difference between one track circuit and the next, or between the rails on either side of an IRJ within one track circuit.
Stagger (physical)	Occurs where two IRJs in a pair of rails are not exactly opposite each other, thus creating a dead section between track circuits or within a track circuit.

Term	Meaning
State (of a function)	Position or action of the equipment. Examples of complementary states are: operated / released, normal / reverse, on / off, raised / lowered, locked / free, enabled / inhibited, energised / de-energised. In data driven systems this is stored as variable data.
State (of the infrastructure)	Configuration of an installation defined by the current design records.
State (of the railway)	The functional position of trackside equipment which should correspond to the state of the controlling device and the signal box indication.
Strap and function test	A circuit function test where the presence and operation of each individual contact is verified by the application of a test strap. This test applies to Signalling works testing.
Stub Ends	A parallel spur in track circuit configuration.
Supervised (level crossing)	Checked by visual observation, either directly or by use of CCTV.
Supervisory (circuit)	Control or indication circuit, particularly in respect of electric traction power supplies.
Systematic failures	Failures due to errors (including mistakes or acts of omission) in any safety life-cycle activity which cause it to fail under some particular combination of inputs or under some particular environmental condition. Systematic failures could arise in any safety life-cycle phase. Examples of systematic failure include: Systematic failures due to errors in the safety requirements specification; Systematic failures due to errors in the design, manufacture, installation, operation of the hardware; Systematic failures due to errors in the design, implementation etc. of the software. (source: BS EN 61508)
Tail cable	A cable between trackside or on-track Signalling equipment and other such equipment or a lineside apparatus housing. For track circuits, see also track cable.
Technician's Terminal	See maintainer's terminal.
Temporary diversion of circuits	The short-term reallocation of cores/contacts or emergency repositioning of an item of equipment which has been operating correctly.
Temporary work	Alterations which remain in use for a limited period of time.
Terminated	A wire that is finally connected in its allotted position. See also top-nutting.
Test	See NR/SMS/Part/A03
Test panel	A control panel provided at the interlocking for testing or maintenance purposes. It may be provided temporarily for a commissioning or the function may be performed by the local panel.
Through circuit	An external circuit drawn in entirety from supply to destination.
Through test	A test to ensure that each individual circuit between the supply source and the final control function operates and is installed throughout as shown in the approved design details. This test applies to Signalling works testing.

Term	Meaning
Tilt Activation and Speed Supervision System (TASS)	The TASS trackside sub system uses a Eurobalise Balise to store infrastructure data that describes the route ahead and transmit this data to a passing TASS capable train. This data is in turn used by the trainborne equipment to supervise the speed and give authority to the trains tilt system to allow tilting where permitted.
Time division multiplex (TDM)	A non-safety-critical serial data transmission system that addresses each channel in turn and converts it into a unique digital code. It is generally used to transmit operating controls and indications between a signal box and interlocking's. See NR/SMS/SB00
Top-nutting	Top-nutting is the connection of temporary or stage work cables or wires to the top of one side of a terminal strip with the links between the terminal columns removed, so as to interlink with existing circuitry beneath.
Train operations processing system (TOPS)	The national computer data system for management of train operations. This is a real-time network that tracks train movements and formations, vehicle identities and goods commodities. It provides input to the national train running system operating on TOPS (TRUST). Also known as total operating and processing system.
Track cable	A track circuit tail cable which connects directly to the rails.
Track jumping	Occurs when a fast moving vehicle passes over a very short track circuit (or a short arm of a longer track circuit) and fails to de-energise the track relay.
Trackside circuit	An external circuit. Run to, or via, an item of trackside or on-track Signalling equipment in a tail cable.
Trackside Apparatus Case	A single or group of apparatus housings at a particular site and the equipment contained therein. (This excludes apparatus housings that perform a main interlocking function, although some interlocking local to ground frames or level crossings may be included.) Alternatively known as lineside locations or colloquial as 'locs'.
Type approval	Approval granted to an individual product.
Uninterruptible power supply (UPS)	A power supply with a secondary source which is capable of providing an uninterrupted changeover in the event of a failure of the incoming supply. It generally consists of low maintenance cells, a charger, voltage regulator, and monitoring, changeover and bypass devices.
Verification	Confirmation by examination and provision of objective evidence that the specified requirements have been fulfilled. (source: BS EN 61508)
Wire count	A visual examination to ensure that the specified number of conductors is securely connected to each terminating point as shown on the wiring diagram and contact analysis, and that the conductors are correctly labelled.
Wrong side failure	A failure which reduces the protection normally provided by the Signalling system and increases the risk of an incident. Also known as safety-critical failure.

END

Includes:	Powered Point Operating Equipment
Excludes:	Rail Clamp Point Lock (RCPL), In-Bearer Clamp Lock (IBCL), HPSS, T72 and Mechanical points

GENERAL

Before the Facing Point Lock (FPL) test is carried out, a safe system of work shall be established so that a Signaller cannot set a route over, or control the points being tested (See NR/SMS/PartA/A04 (Method Statement Summary).

Record Keeping, FPL records shall be kept on the Points System Record Card.

1. Test

NOTE: *This test requires the 3.5mm/5mm point checking gauge and a 1.5mm gauge.*

1.1 For each closed switch position, place the 3.5mm end of the FPL gauge between the switch and stock rail at a point in line with the bolt securing the stock rail to the first slide chair.

1.2 Manually operate the points and check that the lock does not enter the notch in the lock slide.

a) If the lock fails to enter the lock notch, then this is a pass and you shall proceed to step 1.3. This result shall be recorded.

b) If the lock enters the lock notch, then this is a failure and shall be recorded, reported to ICC and investigated.

c) The 3.5mm test shall then be repeated using the 5mm gauge.

d) If the lock fails to enter the lock notch, then this shall be recorded. The gauge of the points shall now be adjusted to bring them back to a position where they fail the 3.5mm test.

e) If the lock enters the lock notch, the test (5mm) is a failure and shall be recorded, reported to ICC and investigated.

f) Additional gauges shall be added until the lock fails to enter the lock notch, this shall be recorded, reported to ICC and the level three on-call engineer advised.

NOTE: *If the lock blades or lock dogs are worn the level three on-call engineer can defer the renewal for a maximum of 48 hours, only if the points can be adjusted to fail when the 5mm gauge when it is inserted as described in 1.1.*

NOTE: *The recording of the extent of the gauge failure is required to allow hazard rating to be calculated.*

g) After 48 hours the facing point route shall be signed out of use (unless it is mechanically secured) until the renewal has been completed.

1.3 Place the 1.5mm FPL gauge between the switch and stock rail at a point in line with the bolt securing the stock rail to the first slide chair.

1.4 Manually operate the points and check that the lock enters the notch in the lock slide.

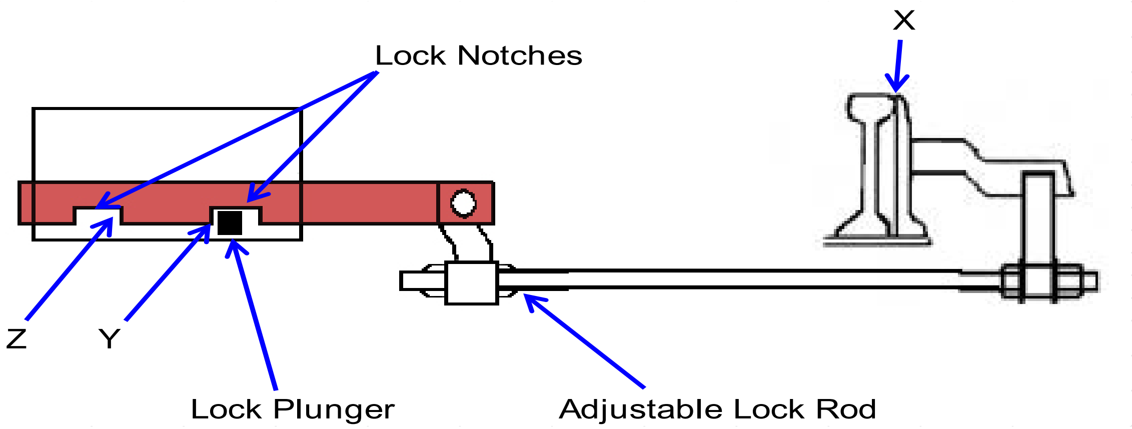

Figure 1 – FPL Blade Connections

1.5 With point switch fully closed (X), confirm there is a 1.5mm clearance on each lock face (Y & Z) see Figure 1.

1.6 Adjust and retest as necessary.

1.7 Record the results and details of any adjustments made on the record card.

1.8 Restore the points.

1.9 The final check before completion of the work is to ask the Signaller to operate the points to normal and reverse positions (twice if possible). Observe correct operation.

END

Includes:	All Mechanical Point
Excludes:	All other points

GENERAL

Before the Facing Point Lock (FPL) test is carried out, a safe system of work shall be established so that a Signaller cannot set a route over or control the points being tested, see NR/SMS/PartA/A04 (Method Statement summary).

1. Test

NOTE: *This test requires the 3.5mm/5mm point checking gauge and a 1.5mm gauge.*

1.1 Check that the travel of the lock plunger is approximately 215mm (8.5 inches).

1.2 Check that, in the unlocked position, the clearance between the lock stretcher and the end of the lock plunger is 19mm ±6.5mm (0.75 inches ±0.25 inches) adjust as necessary.

1.3 For each closed switch position, place the 3.5mm end of the FPL gauge between the switch and stock rail, at a point in line with the bolt securing the stock rail to the first slide chair.

1.4 Manually operate the points and check that the lock does not enter the notch in the lock slide.

a) If the lock plunger fails to enter the lock notch, then this is a pass and you shall proceed to step 1.5. This result shall be recorded.

b) If the lock plunger enters the lock notch, then this is a failure and shall be recorded, reported to ICC and investigated.

c) The 3.5mm test shall then be repeated using the 5mm gauge.

d) If the lock plunger fails to enter the lock notch, then this shall be recorded. The gauge of the points shall now be adjusted the points to bring them back to a position where the they fail the 3.5mm test.

e) If the lock plunger enters the lock notch, the test (5mm) is a failure and shall be recorded, reported to ICC and investigated.

f) Additional gauges shall be added until the lock plunger fails to enter the lock notch, this shall be recorded, reported to ICC and the level three on-call engineer advised.

NOTE: *If the lock plunger or lock notch is worn, the level three on-call engineer can defer the renewal for a maximum of 48 hours, only if the points can be adjusted to fail when the 5mm gauge when it is inserted as described in 1.3.*

NOTE: *The recording of the extent of the gauge failure is required to allow hazard rating to be calculated.*

g) After 48 hours the facing point route shall be signed out of use (unless it is mechanically secured) until the renewal has been completed.

1.5 Place the 1.5mm FPL gauge between the switch and stock rail at a point in line with the bolt securing the stock rail to the first slide chair.

1.6 Manually operate the points and check that the lock plunger enters the notch in the lock slide.

1.7 Adjust and retest as necessary.

1.8 Record the results and any adjustments made on the record card.

1.9 Request the Signaller to operate the points to normal and reverse positions (twice if possible). Observe correct operation.

END

Includes:	Rail Clamp Point Lock (RCPL), In-Bearer Clamp Lock (IBCL)
Excludes:	All Powered Point Machines and Mechanical points

GENERAL

Before the FPL test is carried out, a safe system of work shall be established so that a Signaller cannot set a route over or control the points being tested. See NR/SMS/PartA/A04 (Method Statement Summary).

Do not put any part of your hand between the stock and switch rail.

Record Keeping, FPL records shall be kept on the Points System Record Card.

All adjustments shall be classed as corrective maintenance.

Check detection by either connecting a meter to the outgoing KR circuit or in liaison with the Signaller.

1. FPL Safety Test

These steps shall be undertaken for both normal and reverse positions of the points.

This test requires the 3.5mm/5mm point checking gauge and a 1.5mm gauge.

1.1 Place the points on manual.

1.2 Check the correct voltage is present on the outgoing KR circuit for the mechanism being tested.

For each Lock Body mechanism:

RCPL Only

1.3 Place the 3.5mm end of the FPL gauge between the switch and stock rail at a point in line with the bolt securing the stock to the first slide chair.

1.4 Manually operate the points and check that the lock slide does not complete its travel, and the lock arm does not rise up and engage behind the locking piece.

a) Check that detection is broken.

b) If the lock slide fails to complete its travel, then this is a pass, proceed to step 1.5. This result shall be recorded.

c) If the lock slide completes its travel, then this is a failure and shall be recorded, reported to ICC and investigated.

d) The 3.5mm test shall then be repeated using the 5mm gauge.

e) If the lock slide fails complete its travel, this shall be recorded.

The packing of the points shall now be adjusted to bring them back to a position where they fail the 3.5mm test (See Appendix A).

When the points are returned to gauge you can proceed to step 1.5.

f) If the lock slide completes it travel, the test (5mm) is a failure and shall be recorded, reported to ICC and investigated.

g) Additional gauges or packing shall be added until the lock slide fails to complete its travel, this shall be recorded, reported to ICC and the level three on-call engineer advised.

If the fixed or adjustable cams are worn the level three on-call engineer can defer the renewal for a maximum of 48 hours, only if the points can be adjusted to fail when the 5mm gauge when it is inserted as described in 1.3.

The recording of the extent of the gauge failure is required to allow hazard rating to be calculated.

h) After 48 hours the facing point route shall be signed out of use (unless it is mechanically secured) until the renewal has been completed.

1.5 Place the 1.5mm gauge between the switch and stock rail in line with the lock arm.

a) Manually operate the points and check that the lock arm fully engages, and the drive lock slide fully completes its stroke.

b) Check that detection is made.

<u>IBCL Only</u>

1.6 Place the 3.5mm end of the FPL gauge between the switch and stock rail at a point in line with the lock arm.

1.7 Manually operate the points and check that the lock slide does not complete its travel, and the lock arm does not rise up and engage behind the locking piece (See Table 1 for dimensions).

Condition	**Mk 2**	**Mk 3**
Locked	> 25mm protrusion beyond lock body	> 71mm protrusion beyond lock body

Table 1 – Drive Lock Slide Protrusions when locked

1.8 Check that detection is broken.

a) Check that detection is broken.

b) If the lock slide fails to complete its travel, then this is a pass, proceed to step 1.9. This result shall be recorded.

c) If the lock slide completes its travel, then this is a failure and shall be recorded and investigated.

d) The 3.5mm test shall then be repeated using the 5mm gauge.

e) If the lock slide fails complete its travel, then this shall be recorded, reported to ICC and investigated.

The packing of the points shall now be adjusted to bring them back to a position where they fail the 3.5mm test (See Appendix A).

When the points are returned to gauge you can proceed to step 1.9.

f) If the lock arm completes it travel, the test (5mm) is a failure and shall be recorded, reported to ICC and investigated.

g) Additional gauges or packing shall be added until the lock slide fails to complete its travel, this shall be recorded, reported to ICC and the level three on-call engineer advised.

If the fixed or adjustable cams are worn the level three on-call engineer can defer the renewal for a maximum of 48 hours, only if the points can be adjusted to fail when the 5mm gauge when it is inserted as described in 1.6.

The recording of the extent of the gauge failure is required to allow hazard rating to be calculated.

h) After 48 hours the facing point route shall be signed out of use (unless it is mechanically secured) until the renewal has been completed.

1.9 Place the 1.5mm gauge between the switch and stock rail in line with the lock arm.

a) Manually operate the points and check that the lock arm fully engages, and the drive lock slide fully completes its stroke. Refer to Table 1 for dimensions.

b) Check that detection is made.

1.10 Restore the points to power.

1.11 Record the results of the FPL test on the record card.

1.12 The final check before completion of the work is to ask the Signaller to operate the points to normal and reverse (twice if possible). Observe correct operation.

APPENDIX A - Adjustment (Packing)

If either lock fails the FPL test, the lock shall be adjusted as follows:

If more than a 0.6mm shim is required, check for signs of a run-through by examining the switch rail and stretcher bars for damage.

Check for wear / damage on the locking piece, locating studs (**Mk1 only**), lock arm and inner edges of the switch and stock rails.

2. Fine Adjustment

2.1 Inset shim plates (0.3mm, 0.6mm & 1.6mm) behind the locking piece of the lock body mechanism in the smallest possible incremental steps as listed within the table, up to a maximum total of 4mm to a point at which the lock fails during the 3.5mm gauge test. For details see Table 2.

2.2 Renew tab washers.

2.3 Repeat NR/SMS/PartB/003 (Facing Point Lock Tests (Clamp Lock)).

Incremental Thickness	Packing Arrangement	Incremental Thickness	Packing Arrangement
0.3mm	**(1 x 0.3)**	2.8mm	(1 x 1.6 & 1 x 0.6 & 2 x 0.3)
0.6mm	(1 x 0.6)	**3.0mm**	**(5 x 0.6)**
0.9mm	**(1 x 0.6 & 1 x 0.3)**	3.1mm	1 x 1.6 & 2 x 0.6 & 1 x 0.3)
1.2mm	(2 x 0.6)	**3.2mm**	**(2 x 1.6)**
1.5mm	**(2 x 0.6 & 1 x 0.3)**	3.3mm	(5 x 0.6 & 1 x 0.3)
1.6mm	(1 x 1.6)	**3.4mm**	**(1 x 1.6 & 3 x 0.6)**
1.8mm	**(3 x 0.6)**	3.5mm	(2 x 1.6 & 1 x 0.3)
1.9mm	(1 x 1.6 & 1 x 0.3)	**3.6mm**	**(6 x 0.6)**
2.1mm	**(3 x 0.6 & 1 x 0.3)**	3.7mm	(1 x 1.6 & 3 x 0.6 & 1 x 0.3)
2.2mm	(1 x 1.6 & 1 x 0.6)	**3.8mm**	**(2 x 1.6 & 1 x 0.6)**
2.4mm	**(4 x 0.6)**	3.9mm	(6 x 0.6 & 1 x 0.3)
2.5mm	(1 x 1.6 & 1 x 0.6 & 1 x 0.3)	**4.0mm**	**(1 x 1.6 & 4 x 0.6)**
2.7mm	**(4 x 0.6 &1 x 0.3)**		

Table 2 – Fine Adjustment

3. Coarse Adjustment

3.1 If greater than 4mm of fine packing is required, insert packing plates (3mm &1.6mm) between the switch rail bracket and the switch rail web.

3.2 Adjust / renew stretcher bar and tie bar.

3.3 Reset actuator packing to maintain the 3mm clearance between the lock arm and the drive lock slide.

3.4 Repeat NR/SMS/PartB/003 (Facing Point Lock Tests (Clamp Lock)).

3.5 Carry out NR/SMS/PartB/014 (Lock and Detector Full Test (Clamp Lock)).

END

Includes:	HPSS
Excludes:	All other Powered Point Machines and Mechanical points

GENERAL

Ask the Signaller to operate the points to identify the correct points are being tested.

Before the Facing Point Lock (FPL) test is carried out, a safe system of work shall be established so that a Signaller cannot set a route over or control the points being tested, See NR/SMS/PartA/A04 (Method Statement Summary).

This FPL test is carried out with the machine under power, controlled by the Signaller.

To avoid injury whilst placing and removing gauges, it is recommended that you use the Hands-Free gauges (ask your SM(S) or hold the gauges with a pair of pliers or mole-grips.

Detection is confirmed by referring to the meter connected to the KR circuit at the location/disconnection box.

The HPSA Handset shall not be used to confirm detection as it is powered from a port on the ECU separate to the outgoing detection circuitry.

It is essential to confirm that detection is made and broken by referring to the meter only.

The secondary (supplementary) detection tests confirm the Rail Position Sensors shall not give detection when an obstruction is placed between the stock and switch rail, even though the rail bends around the obstruction.

This test requires:

a) Voltmeter, HPSA Handset (and passwords for old variants of Psion Handset).

b) Two 3.5mm point checking gauges. (Hands-free FPL Gauge recommended).

c) Two 8 mm (CEN 54) or two 10mm (NR60 / RT60).

Before carrying out the test, connect the HPSA Handset and check that each closed switch position is showing 0mm.

If the value is outside the limits -0.1mm to +0.5mm (primary / toe sensors) and/or –1mm to +2mm (secondary / supplementary sensors), this could indicate that the system is not securely fixed and it could impact performance.

Before and after values shall be recorded onto the record card so that any movement between maintenance visits is recorded.

If any excess movement is recorded, it shall be investigated and be reported.

1. Test

1.1 Connect the meter to the outgoing KR circuit at the location/disconnection box.

1.2 Perform a Datum Reset as detailed in NR/SMS/PartC/PC51 (High Performance Switch System (HPSS)) - Appendix A.

1.3 Check that the correct voltage is present on the outgoing KR circuit for the points being tested.

1.4 Place the 3.5mm gauge between the open switch and stock rails at a point in line with the centreline of the switch rail drive bracket. Hands-Free FPL Gauge recommended.

The gauge shall be inserted to prevent the switch rail from bending under the gauge and making detection.

1.5 Ask the Signaller to operate the points and ask what detection, if any, is given.

1.6 Check that no voltage is present on the outgoing KR circuit, by referring to the meter.

1.7 Place another 3.5mm gauge between the open switch and stock rails at a point in line with the centreline of the switch rail drive bracket. Hands-Free FPL Gauge recommended.

1.8 Ask the Signaller to operate the points and ask what detection, if any, is given.

1.9 Check that no voltage is present on the outgoing KR circuit, by referring to the meter.

1.10 Remove both gauges (operation of points is required).

1.11 Operate points under power and using the HPSA Handset, check that each supplementary position shows 0+/- 0.5mm at the closed position.

Check that any residual switch opening at the closed side is less than 2mm at the supplementary detection positions.

1.12 At the rear most pair of supplementary detection sensors place an 8 mm (CEN 54) or 10mm (NR60 / RT60) gauge between the open switch and stock rail at a point in line with the centre line of the switch rail drive bracket, power operate the points to close the open switch rail.

NOTE: *The purpose of this test is to confirm that the correct number of supplementary sensors have been selected during the datum reset procedure. Therefore, the testing of the supplementary detection sensor is only required to be completed with the points in either the normal or reverse position.*

1.13 Check that no voltage is present on the outgoing KR circuit, by referring to the meter. If voltage is present on the outgoing KR circuit:

a) Check that any residual switch opening at the closed side is less than 2mm at the supplementary detection positions.

b) Check on the HPSA Handset that the correct number of supplementary sensors have been commissioned during the datum reset procedure.

1.14 Remove all gauges (requires operation of Points).

1.15 Observe correct operation of the points to the normal and reverse position. The time taken is normally 4 seconds. If the time taken is greater than 5 seconds, make arrangements to carry out further investigation.

1.16 Record all sensor readings (open and closed positions) from the HPSA Handset, and any adjustments that have been carried out, on the record card.

END

Includes:	T72 Point machine
Excludes:	All other Powered Point Machines and Mechanical points

GENERAL

Before the Facing Point Lock (FPL) test is carried out, a safe system of work shall be established to prevent a Signaller setting a route over or operating the points being tested, see NR/SMS/PartA/A04 (Method Statement Summary).

Isolate the T72 point machine by moving the selector lever to the 'Hand' position.

When performing this test, check that when the clutch slips, the switch rail is tight against the inserted gauge.

1. Facing Point Lock Test

1.1 Disconnect the detection at the junction box by removing links T1 number 1 and T1 number 3.

1.2 Remove the VCC cover and the internal detector cover.

1.3 Connect a meter, set to the ohms range, to the terminals on the left hand VCC unit according to lie of points.

a) If the left-hand switch is closed and locked, use terminals 1 and 5.

b) If the right-hand switch is closed and locked, use terminals 4 and 8.

1.4 Measure the resistance (approximately 33k ohms).

1.5 Gently break each contact in turn and confirm that the reading is lost.

<u>If left hand switch is closed and locked:</u>

The contacts are the lock proving contacts on the left hand VCC and the open switch proving contacts on the right hand VCC.

<u>If right hand switch is closed and locked:</u>

The contacts are the open switch proving contacts on the left hand VCC and the lock proving contacts on the right hand VCC.

1.6 Place a 3.5 mm thick gauge between the switch blade and stock rail at a point in line with the hollow bolt securing the VCC body to the stock rail.

1.7 Manually operate the points, check that the cranked ‘C’ head does not engage the locking piece and observe that the detection is broken.

1.8 Replace the 3.5 mm gauge with the 1.5 mm gauge.

1.9 Manually operate the points. Check that the cranked ‘C’ head fully engages the locking piece and observe that detection is made.

1.10 Remove the gauge. If the lock has failed the test, perform steps 1.11 and 1.12. If the lock passes the test, continue from 1.13.

1.11 Adjust the shims under the ‘C’ heel and repeat clauses 1.6 to 1.10.

1.12 Carry out NR/SMS/PartB/Test/007 (Detection Test (VCC Detector)).

1.13 Remove the meter and replace the internal detector cover and replace and secure the VCC cover.

1.14 Repeat 1.2 to 1.13 for the other lock.

1.15 Replace links T1 number 1 and T1 number 3.

1.16 Record the results and details of any adjustments on the record card.

1.17 Restore the points to service operation.

1.18 Ask the Signaller to operate the points to Normal and Reverse positions (twice if possible). Observe correct operation.

END

Before the detection test is carried out, a safe system of work shall be established so that a signaller cannot set a route over, or control the wheelstop being tested (See NR/SMS/ Part/A04).

The detection test shall only be carried out using Manual operation only.

Standard gauges are required, but are used in non-standard ways.

DETECTION TEST

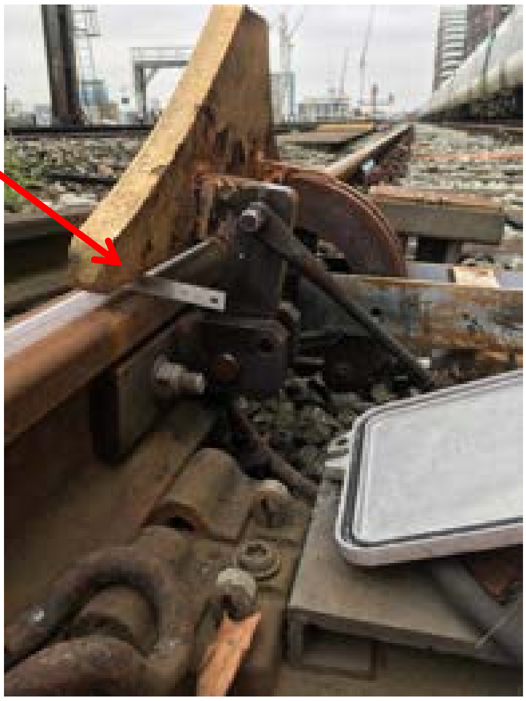
1. Detection Test – Normal Position

This test requires a meter and a 1.5mm or 2mm point checking gauge.

1.5mm or 2mm gauges are 15mm wide, as shown in diagram 1 below

Diagram 1 – 15mm gauge

1.1 With the 15mm point checking gauge place between the top of the rail head and wheel stop whilst slowly operating the wheel stop to the normal position.



1.2 Electrically prove that, with the gauge in place, normal detection is not achieved.

1.3 If normal detection is achieved the wheel stop circuit controller shall be adjusted/reset and the test restarted from clause 1.1

2. Detection Test – Reverse Position

- This test requires a meter and a 3.5mm/5mm point checking gauge.
- 3.5mm - 5mm gauges are 80mm tall, as shown in diagram 2.

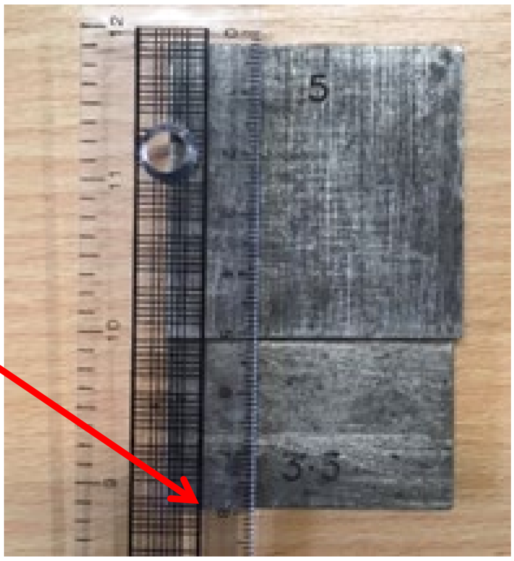


Diagram 2 – 80mm Gauge

2.1 With the 80mm length of the 3.5mm/5mm gauge placed between the top edge of the wheel stop casting and the wheel stop in line with the first horizontal plate. Slowly operate the wheel stop to the reverse position

2.2 Electrically prove that, with the gauge in place, reverse detection is not achieved.

2.3 If reverse detection is achieved the wheel stop circuit controller shall be adjusted/reset and the test restarted from clause 2.1

3. Final Check

3.1 Ask the Signaller to operate the points to normal and reverse positions (twice if possible). Observe correct operation.

END

GENERAL

Isolate the supply to the point machine and operate the points manually. Disconnect the point control links in the junction box or apply an alternative safe system of work, See NR/SMS/PartA/A04 (Method Statement Summary).

More information on performing this test can be found in NR/SMS/Appendix/02 (General Information on Ansaldo Signalling Equipment).

1. Detection Test

This test requires the 6 mm 'U' shaped gauge, 13/26 mm gauge, rule, small inside callipers (for measuring tappet screw / locknut assembly), and a meter.

1.1 Check that the closed switch rail is fully up against the stock rail and is locked and also that there are no obstructions between the open switch rail and stock rail.

1.2 Disconnect the detection at the junction box by removing links T1 number 1 and T1 number 3.

1.3 Remove the VCC cover and the internal detector cover.

1.4 Connect a meter, set to the ohms range, to the terminals on the left hand VCC unit according to lie of points.

If the left-hand switch rail is closed and locked: use terminals 1 and 5.

If the right-hand switch rail is closed and locked: use terminals 4 and 8.

1.5 Measure the resistance (approximately 33 k ohms).

1.6 Manually operate the switch blade to the opposite lie of points.

1.7 While manually closing the switch rail, gauge the amount the crank head engages the locking piece, when the lock contacts are just made.

Check that the side of the gauge is fully against the face of the crank head, as detailed in NR/SMS/Appendix/02 (General Information on Ansaldo Signalling Equipment).

Switch Closed and Locked

1.8 Manually operate the points and check that the switch rail is closed and locked on the side to be tested.

1.9 Check that the crank head fully engages the locking piece, see NR/SMS/Appendix/02 (General Information on Ansaldo Signalling Equipment).

1.10 Gauge the stroke of the detector cam shaft.

Insert the 6 mm 'U' shaped gauge between the hexagonal nut and the rear of the detector frame at approximately 45° to straddle one of the hexagonal fixing screws.

The gauge shall be a sliding fit (6 mm + 1 mm). If the gap is incorrect adjust the stroke, see NR/SMS/Appendix/02 (General Information on Ansaldo Signalling Equipment).

1.11 Check that the open switch detection contacts are broken and that the closed switch and lock proving contacts are made (i.e. not in contact with the cam plastic cover).

1.12 Remove the gauge and open the switch blade.

1.13 Measure the overall length of the tappet screw and lock nut assembly (maximum 17mm).

Details and action to take if over 17mm are in NR/SMS/Appendix/02 (General Information on Ansaldo Signalling Equipment).

If any adjustment has been made, the test shall be repeated

1.14 Remove the meter, replace the internal detector cover, and replace and secure the VCC cover.

1.15 Repeat tests 1.4. to 1.14 on the right hand VCC.

1.16 Replace links T1 number 1 and T1 number 3.

1.17 Ask the Signaller to operate the points to Normal and Reverse positions (twice if possible). Observe correct operation.

END

GENERAL

Ask the Signaller to operate the points to identify that the correct points are being tested.

Before the test is carried out, a safe system of work shall be established so that a Signaller cannot set a route over, or control, the points being tested (See NR/SMS/Part/A04).

These tests shall be carried out under powered operation in liaison with the Signaller.

To avoid injury whilst placing and removing gauges, it is recommended that you use the Hands-Free gauges (ask your SM(S)) or hold the gauges with a pair of pliers or mole-grips.

Due to the possibility of a small gap between the closed switch and stock rails, the Handset reading is unlikely to show the exact value (thickness) of the test gauge. If a residual gap was present without the gauge inserted, then the Handset values can be expected to under- read by an amount equivalent to the residual gap.

1. Brake Torque Test

1.1 Disconnect the brake power cable, ECU connector J3.

1.2 Ask the Signaller to operate the points to the opposite position and carry out the following during the movement:

a) Manually release both brakes by compressing both brake handles to allow the points to drive.

b) Once the points have started to move, apply one of the brakes by releasing one of the brake handles and confirm the points cease to move.

c) Manually release by compressing both brake handles together and confirm the points complete their movement to the opposite position under powered operation within 6 seconds.

d) Repeat 1.2 for the other brake handle.

1.3 Reconnect the brake power cable (J3) and ask the Signaller to operate the points to confirm satisfactory operation.

2. Toe Sensor Integrity Test

2.1 Using the HPSA Handset, carry out the ECU Datum Reset procedure as detailed in NR/SMS/PartC/PC51 (High Performance Switch System (HPSS)) Appendix A.

2.2 Place a 3.5mm gauge between the open switch and stock rails at a point in line with the centre line of the switch rail drive bracket. Power-operate the points to the normal position. Hands-Free FPL Gauge recommended.

2.3 Using the HPSA Handset, check that the measured position at the closed switch rail is 3.5mm +/- 0.5mm. Check that the open rail position has also decreased by 3.5mm +/- 0.5mm.

2.4 Place a 3.5mm gauge between the open switch and stock rails at a point in line with the centre line of the switch rail drive bracket. Power-operate the points to the reverse position. Hands-Free FPL Gauge recommended.

2.5 Using the HPSA Handset, check that the measured position at the closed switch rail is 3.5mm +/- 0.5mm. Check that the open rail position has also decreased by 3.5mm +/- 0.5mm.

2.6 Remove both gauges (operation of points is required).

NOTE: *This test confirms the integrity of the Toe Sensor LVDTs and is not an alternative to the FPL test.*

3. Supplementary Sensor Integrity and Detection Test

3.1 Connect the meter to the outgoing KR lines at the location/disconnection box.

3.2 Operate points under power and using the HPSA Handset, check that each supplementary position shows 0+/- 0.5mm at the closed position, and that any residual switch opening at the closed side is less than 2mm at the supplementary detection positions.

3.3 Carry out the same tests as described in Section 2 at each supplementary detection position, using 8mm (CEN54) or 10mm (NR60/RT60) gauges.

It is strongly recommended that the Hands-Free Detection Gauge (PADS No. 086/035401) is used (placed on the stock rail), to avoid injury.

3.4 Using the HPSA handset, check that the relevant sensor shows the measured position at the closed switch rail is equal to the thickness of the gauge, minus the residual switch opening (thickness of the gauge +/- 0.5mm).

Check that the open rail position has also decreased by the same amount (thickness of the gauge +/- 0.5mm).

3.5 Check that no voltage is present on the outgoing KR circuit.

3.6 Repeat 3.1 to 3.4 for all other Supplementary Sensors.

3.7 Remove all gauges (requires operation of points).

END

GENERAL

Isolate the mechanism by turning to the "Manual" position on the hydraulic pack. Disconnect the point detection from the KR lines or apply an alternative safe system of work, see NR/SMS/PartA/A04 (Method Statement Summary).

Gauges: 2mm and 4mm detection gauge.

1. Switch Closed and Locked

1.1 Check the correct voltage is present on the outgoing KR circuit in the associated disconnection box for the SO Supplementary Drive Unit being tested.

1.2 Insert the 4mm gauge between the switch and stock rail at a point in line with the drive rod.

1.3 Manually operate the points and test that detection is broken.

1.4 Where adjustment is required, remove the horizontal drive pin, loosen the gauge adjusting lug locking screws, and wind the gauge adjusting lug out (away from the SO unit) to adjust.

Replace the horizontal drive pin. Repeat from 1.2 as necessary.

Check that the drive shuttle does not drop out of the gauge adjusting lug during adjustment.

Check that the gauge adjusting lug locking screws are re-secured once adjustments are complete.

1.5 Repeat using the 2mm gauge and test that detection is made, and the correct voltage is present on the KR circuit.

1.6 Where adjustment is required, remove the horizontal drive pin, loosen the gauge adjusting lug locking screws, and wind the gauge adjusting lug in (towards the SO unit) to adjust.

Replace the horizontal drive pin. Repeat from 1.2 as necessary.

Check that the drive shuttle does not drop out of the gauge adjusting lug during adjustment.

Check that the gauge adjusting lug locking screws are re-secured once adjustments are complete.

1.7 Repeat tests 1.1 to 1.6 for each drive.

1.8 Restore the points to power.

1.9 The final check before completion of the work is to ask the Signaller to operate the points to normal and reverse positions (twice if possible). Observe correct operation.

END

Excludes:	Detectors are excluded from this test if one of the following conditions is met: • The detector is part of a detection circuit wired directly to a SSI points module without any intermediate relays • The detector forms part of a circuit which feeds polar or phase sensitive detection relays (e.g., BR 961, VL1) over a two-wire circuit indicating both normal and reverse detection • There is another detector, clamp lock or point machine in the circuit between the BR998 detector and the detection relay(s) • The detector is part of a detection circuit wired directly to a Westrace Mk2 SOM24 without any intermediate relays

GENERAL

If applicable, isolate the supply to the point machine and operate points manually.

Disconnect the point detection from the KR lines or apply an alternative safe system of work, see NR/SMS/PartA/A04 (Method Statement Summary).

When taking measurements with respect to the chassis, check a good electrical connection to the chassis is obtained, otherwise false readings might be obtained.

1. Electrical Test

1.1 Using the maintenance diagrams identify the terminals which carry the outgoing feed to the detection relay(s) for each lie of the points.

For points with electrical detection made for one position only (e.g., train operated) arrange for the points to be in the detection made position.

<u>Tasks 1.2 to 1.10 Apply to DC Detection Circuits Only</u>

1.2 With the detection made, measure using a DVM with a 150kΩ shunt the outgoing detection voltage for the current position of the points.

Check that this voltage is correct to diagram and note this.

1.3 Transfer the DVM to the terminals for the outgoing detection for the opposite detection and measure the voltage. If a voltage greater than 5% of the voltage measured in 1.2 is obtained, your SM(S) shall be informed immediately.

1.4 Leave the DVM connected and have the points moved to the opposite position.

1.5 Measure the voltage. Check this voltage is the same as obtained in 1.2.

NOTE: *This might not apply where electrical detection is proved for one position of the points only.*

1.6 Transfer the DVM to the terminals used in 1.2 and measure the voltage. If a voltage greater than 5% of the voltage measured in 1.5 is obtained, your SM(S) shall be informed immediately.

1.7 Have the points moved to their original position and move the DVM to terminals 2 and 5 of the detector. Measure the voltage and check it is the same as measured in 1.2 (ignore the polarity).

1.8 Connect the DVM between terminal 2 and the metal detection chassis. Measure the voltage and note it as V1.

1.9 Connect the DVM between terminal 5 and the metal detection chassis. Measure the voltage and note it as V2.

1.10 Report immediately to your SM(S) if:

a) V1 or V2 is more than 60% of that measured in 1.2.

b) V1 + V2 is more than 80% of that measured in 1.2.

<u>Tasks 1.11 to 1.19 Apply to AC Detection Circuits Only</u>

1.11 Using a DVM (with a input impedance of least 1Mohm) set the range to DC volts and connect the red and one of the black terminals of an AC busbar earth test adaptor.

Connect the green and other black terminal of the adaptor together and check that the obtained reading is at least +8V.

Note this voltage as Vb.

If the voltage is <+8V, change the battery in the adaptor and carry out step 1.11 again.

1.12 Disconnect the green and black terminals of the adaptor from each other and connect them to the outgoing terminals of the detector corresponding to the current position of the points. Measure the voltage and note this voltage.

1.13 Transfer the green and black terminals of the adaptor to the outgoing terminals for the Normal BX and Reverse BX detection lines. Measure any voltage present. If a voltage greater than 5% of that recorded in 1.12 is found, inform your SM(S) immediately.

1.14 Transfer the green and black terminals of the adaptor to the outgoing terminals for the Normal NX and Reverse NX detection lines. Measure any voltage present. If a voltage greater than 5% of that recorded in 1.12 is found, inform your SM(S) immediately.

1.15 Arrange to have the points moved to the opposite position and repeat steps 1.12 to 1.14.

1.16 Arrange to have the points moved to their original position and transfer the green and black terminals of the adaptor to terminals 2 and 5 of the detector. Measure the voltage and check it is the same as measured in 1.12 (ignore the polarity).

1.17 Connect the black terminal of the adaptor to terminal 2 of the detector and the green terminal of the adaptor to the metal chassis of the detector. Measure the voltage and note it as V1.

1.18 Connect the black terminal of the adaptor to terminal 5 of the detector and the green terminal of the adaptor to the metal chassis of the detector. Measure the voltage and note it as V2.

1.19 Report immediately to your SM(S) if:

a) V1 + V2 is more than 90% of Vb.

b) V1 - V2 is more than 11% of Vb.

2. Microswitch Tests

2.1 With point switch fully closed, insert a 2mm gauge between limit switch tappet screw and plunger button. Observe that detection is lost.

2.2 Repeat using a 1.5mm gauge. Observe that detection remains made.

2.3 Repeat 2.1 and 2.2 for the opposite lie of the points.

3. Train Operated and Yard Points fitted with August 2000 Wiring Modifications Tests

The modified circuit is designed to make sure that the detection fuse will blow through the reverse limit switch contact if a normal contact welds up. This test makes sure that the reverse contact on each limit switch is not high resistance.

3.1 Manually operate the points to the reverse position.

3.2 Disconnect ONE end of ONE short-circuit strap.

3.3 Measure the loop resistance of the micro-switch circuit. Use a multi-meter set to ohms. Place the prods across the end of the disconnected short circuit strap and its associated terminal. The resistance shall be less than 2Ω. If the resistance is more than 2Ω, investigate the cause and take corrective action.

3.4 Remove the meter and reconnect the short-circuit strap.

3.5 Manually operate the points to the normal position.

3.6 Reconnect the detection links.

3.7 Observe that the point indicator only lights up when the points are detected fully in the normal position.

3.8 Observe that the point indicator does not light up after the points have been moved from the normal position until the restoration process is fully complete.

END

Includes:	Point machine internal detectors and external detectors used for main point detection
Excludes:	Supplementary detectors (see NR/SMS/PartB/Test/016) Clamp lock point detectors (see NR/SMS/PartB/Test/013)

GENERAL

Isolate the supply to the point machine and operate points manually.

Disconnect the point detection from the KR lines or apply an alternative safe system of work, see NR/SMS/PartA/A04 (Method Statement Summary).

On WRSL Style 63 Point machines, only section 3 shall be undertaken for the detection test.

Gauges : This test requires the 3.5mm/5mm point checking gauge (slotted gauges).

1. Adjusting Nuts Adjacent to Detection Mechanism

1.1 Check that the points are fully over, locked and in correspondence.

1.2 Check the short detector rod is connected to the closed switch (Figure 1).

1.3 Check the correct voltage is present on the outgoing KR circuit.

1.4 Slacken the red nut to allow a 5mm gauge to be placed between the detector blade and blue nut. DO NOT move the blue nut.

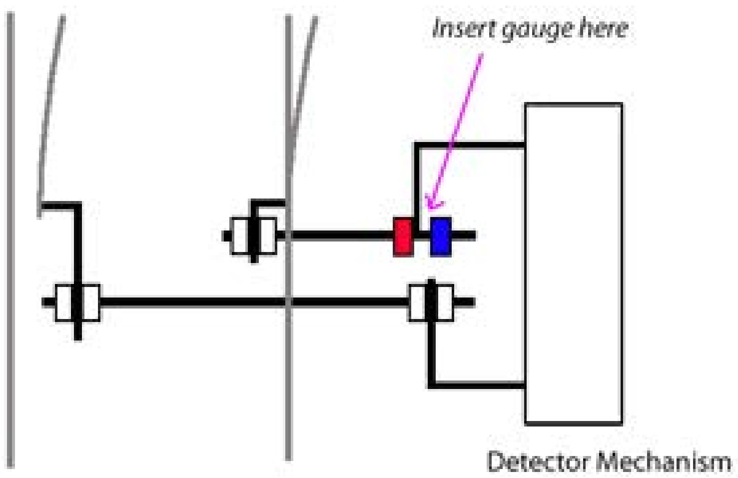

Figure 1 – Detector Mechanism (1)

1.5 Insert the 5mm gauge between the detector blade and the blue nut, re-tighten the red nut.

1.6 Check the detection voltage is lost.

1.7 Replace the 5mm gauge with a 3.5mm gauge and check the detection voltage is present.

1.8 Remove the gauge and re-tighten the red nut, check that the blue has not moved.

1.9 Check the correct voltage is present on the KR circuit.

1.10 Operate the points to the opposite position, lock and check they are in correspondence.

1.11 Check the long detector rod is attached to the closed switch (Figure 2).

1.12 Check the correct voltage is present on the outgoing KR circuit.

1.13 Slacken the pink nut enough to allow a 5mm gauge to be placed between the detector blade and green nut. DO NOT move the green nut.

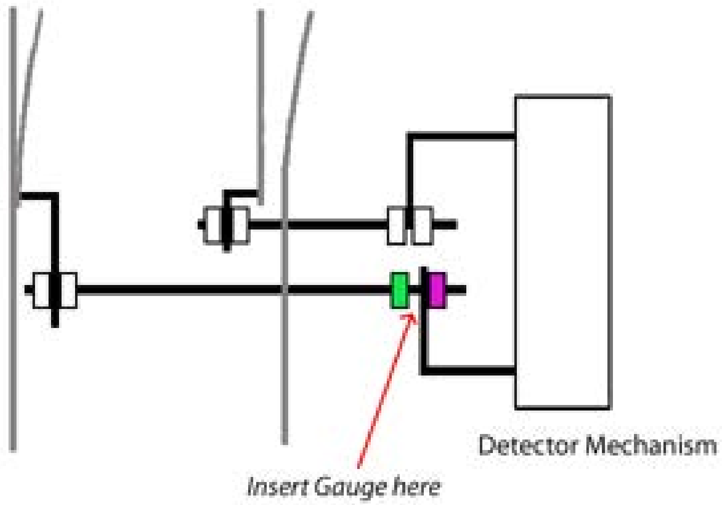

Figure 2 – Detector Mechanism (2)

1.14 Insert the 5mm gauge between the detector blade and the green nut and re-tighten the pink nut.

1.15 Check the detection voltage is lost.

1.16 Replace the 5mm gauge with a 3.5mm gauge and check the detection voltage is present.

1.17 Remove the gauge and re-tighten the pink nut, check that the green nut has not moved.

Any adjustments shall be verified by repeating the test.

1.18 Check the correct voltage is present on the KR circuit.

1.19 Carry out NR/SMS/PartB/Test/001 (Facing Point Lock Tests (Machine)).

The final check before completion of the work is to ask the Signaller to operate the points to normal and reverse positions (twice if possible). Observe correct operation.

2. Adjusting Nuts Fitted on the Switch Rail Extension Ends in the Four Foot

2.1 Check that the points are fully over, locked and in correspondence.

2.2 Check the short detector rod is connected to the closed switch (Figure 3).

2.3 Check the correct voltage is present on the outgoing KR circuit.

2.4 Slacken the red nut to allow a 5mm gauge to be placed between the detector blade and blue nut. Do not move the blue nut.

2.5 Insert the 5mm gauge between the extension piece and the blue nut and re-tighten the red nut.

2.6 Check the detection voltage is lost.

2.7 Replace the 5mm gauge with a 3.5mm gauge and check the detection voltage is present.

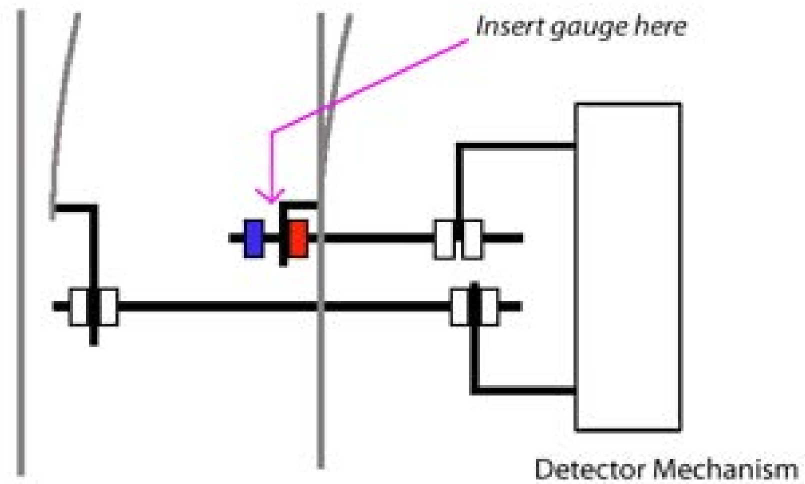

Figure 3 – Detector Mechanism (3)

2.8 Remove the gauge and re-tighten the red nut, check that the blue nut has not moved.

2.9 Check the correct voltage is present on the KR circuit.

2.10 Operate the points to the opposite position, lock and check they are in correspondence.

2.11 Check the long detector rod is attached to the closed switch (Fig 4).

2.12 Check the correct voltage is present on the outgoing KR circuit.

2.13 Slacken the pink nut enough to allow a 5mm gauge to be placed between the extension piece and green nut. Check the green nut does not move.

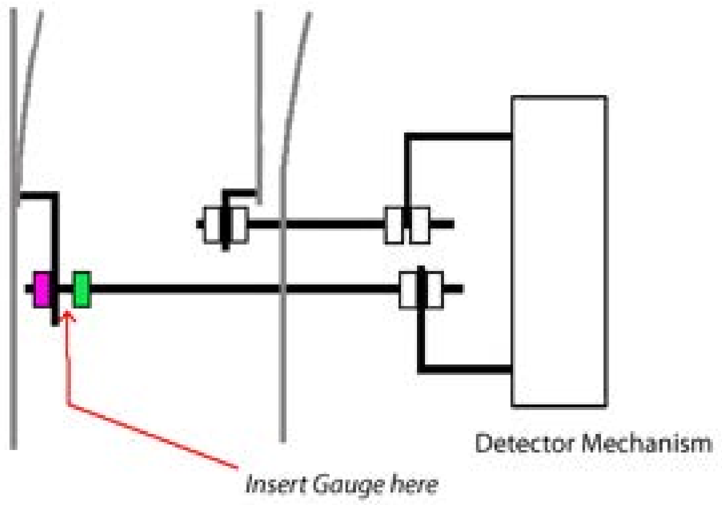

Figure 4 – Detector Mechanism (4)

2.14 Insert the 5mm gauge between the extension piece and the green nut and re-tighten the pink nut.

2.15 Check the detection voltage is lost.

2.16 Replace the 5mm gauge with a 3.5mm gauge and check the detection voltage is present.

2.17 Remove the gauge and re-tighten the pink nut, check that the green nut has not moved.

Any adjustments shall be verified by repeating the test.

2.18 Check the correct voltage is present on the KR circuit.

2.19 Carry out NR/SMS/PartB/Test/001 (Facing Point Lock Tests (Machine)).

2.20 The final check before completion of the work is to ask the Signaller to operate the points to normal and reverse positions (twice if possible). Observe correct operation.

3. WRSL Style 63 Point Machine

Unless this detection test is being done in conjunction with NR/SMS/PartC/PC41 (Point Machine WRSL Style 63) the machine shall be isolated by removal of the motor and detection fuses, or apply an alternative safe system of work (See NR/SMS/Part/A04).

Contact Setting

3.1 Close and lock the points reverse.

3.2 Unlock the points without opening the switch rails.

3.3 Gauge the 2mm gap of both reverse detection contacts (insert and remove 2mm insulated gauge). If the gap is less than 2mm, the points shall be booked out of use.

3.4 Repeat 3.2 and 3.3 for the point's normal position.

Normal Detection

3.5 Lock the points normal.

3.6 Examine the normal detection roller.

NOTE: *It should be free from wear, rotate freely, and drop correctly into the detector blade notch.*

3.7 Check detection is made by connecting a meter across the normal detection terminals on the ohms range.

3.8 Using the 2mm gauge (Position 1 – in Figure 5), check that detection is broken by reference to the meter.

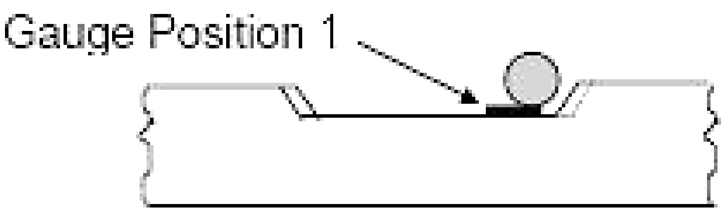

Figure 5 – Gauge Position 1

Any adjustment shall be followed by a repeat of steps 3.7 and 3.8.

3.9 Using the 2mm gauge (Position 2 – Figure 6), check that detection remains made by reference to the meter.

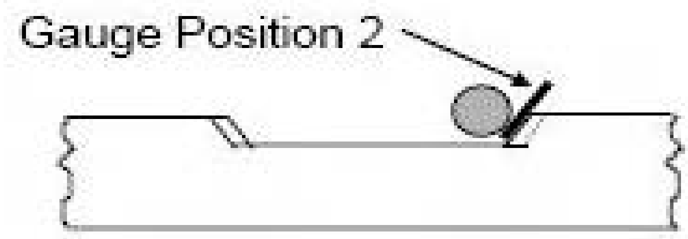

Figure 6 - Gauge Position 2

3.10 Using the 3.5mm gauge (Position 2), check detection is broken.

3.11 Using the 5mm gauge (Position 2), check the normal detection contact gap using the 2mm insulated gauge.

If the gap is less than 2mm, the points shall be booked out of use.

<u>Reverse Detection</u>

3.12 Repeat steps 3.5 - 3.11 for the points in the reverse position (Figure 7).

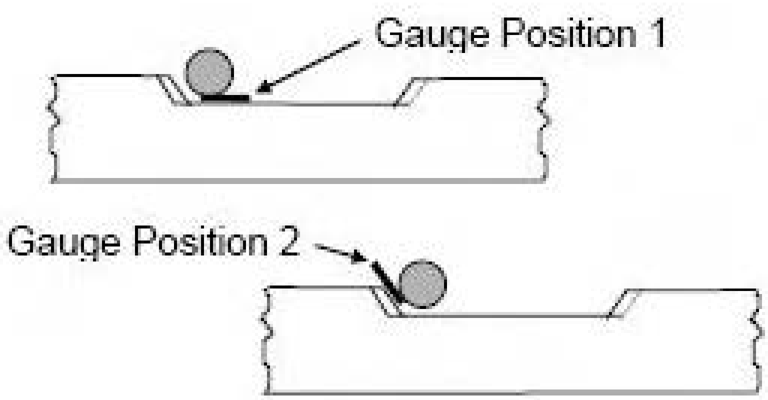

Figure 7 - Gauge Position – Reverse Position

3.13 When work is complete, reset the isolating contacts and restore the motor and detection fuses.

3.14 The final check before completion of the work is to ask the Signaller to operate the points to normal and reverse positions (twice if possible). Observe correct operation.

END

GENERAL

Before this test is carried out, a safe system of work shall be established so that a Signaller cannot clear a protecting signal, or move the points being tested (NR/SMS/Part/A04).

Gauges : This test requires the 3.5mm/5mm point checking gauge and a 2mm gauge.

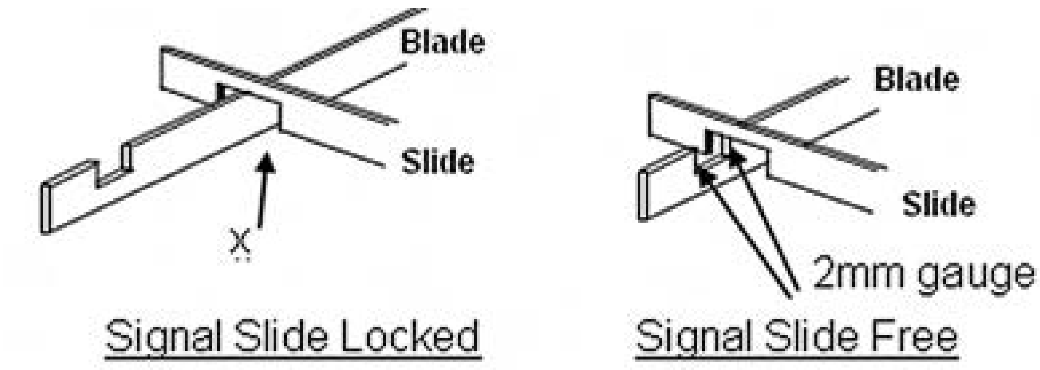

Figure 1 – Signal Slides

1. Detection Test

FOR NORMAL AND REVERSE POSITIONS:

1.1 Each detector blade should have a 2mm clearance to each notch face on each side of the signal slides. Fouling blades can cause a signal to stick off.

1.2 Check clearance ‘x’ between each signal slide notch face and the nearest blade.

Maximum 0.5 inch (13mm) for signals within 25yds (23m) of the signal, this dimension may be increased for distances over 25yds (23m) to cater for the effect of temperature changes.

Where two or more detectors control the same signal, the detector nearest the signal should have the normal clearance. Other detectors should have a progressively increased clearance up to a maximum of 2 inches (51mm) at the last detector if it is more than 200yds (183m) from the signal.

The increase of signal slide clearance should not exceed 1 inch per 100 yds (or 10mm per 36m) of wire run.

1.3 Insert a 5mm gauge between the point switch and stock rail at a position in line with the bolt securing the stock rail to the first slide chair.

1.4 Observe that the signal slides are held by the detector blade. Adjust as necessary and then retest.

1.5 Ask the Signaller to operate the points to normal and reverse positions (twice if possible). Observe correct operation.

END

Includes:	Rail Clamp Point lock (RCPL) & In-Bearer Clamp Lock (IBCL)
Excludes:	All other types of POE

GENERAL

Isolate the mechanism by turning to the 'Manual' position on the hydraulic pack. Disconnect the point detection from the KR lines or apply an alternative safe system of work, see NR/SMS/PartA/A04 (Method Statement Summary).

If any of the following tests fail, carry out NR/SMS/PartB/014 (Lock and Detector full Test (Clamp Lock).

Gauges

a) 2.5mm & 4mm detection gauge (RCPL).

b) 3.5mm & 5mm detection gauge (IBCL).

c) 1.5mm & 2mm micro-switch gauges.

1. Switch Open

1.1 Check the correct voltage is present on the outgoing KR circuit for the mechanism being tested.

1.2 Check the right-hand micro-switch plunger is clear of its cam follower tappet screw.

1.3 Operate the right-hand micro-switch and observe that detection is broken.

2. Switch Closed and Locked

2.1 Check the correct voltage is present on the outgoing KR circuit for the mechanism being tested.

2.2 RCPL Only

Insert the 4mm gauge between the point detector blade lug and the shoulder of the connecting eye; tighten nut and observe that the detection is broken.

IBCL Only

Insert the 5mm gauge between the point detector blade lug and the shoulder of the connecting eye; tighten nut and observe that the detection is broken.

2.3 RCPL Only

Repeat using the 2.5mm gauge and observe the detection is made and the correct voltage is present on the KR circuit.

IBCL Only

Repeat using the 3.5mm gauge and observe the detection is made and the correct voltage is present on the KR circuit.

2.4 Remove the gauge, tighten the nut and check that detection is made.

2.5 Insert the 1.5mm gauge between the left-hand micro-switch plunger and the cam follower tappet screw. Observe the detection is made and the correct voltage is present on the KR circuit.

2.6 Repeat 2.5 using the 2mm gauge and observe that detection is broken.

2.7 Repeat tests 1.1 to 1.3 for the other mechanism.

2.8 Repeat tests 2.1 to 2.6 for the other mechanism.

2.9 The final check before completion of the work is to ask the Signaller to operate the points to normal and reverse positions (twice if possible). Observe correct operation.

END

Clamp Includes:	Rail Clamp Point lock (RCPL) & In-Bearer Clamp Lock (IBCL)
Excludes:	

Isolate the mechanism by turning to the 'Manual' position on the hydraulic pack. Disconnect the point detection from the KR lines or apply an alternative safe system of work (See NR/SMS/Part/A04).

Detection shall always be checked by reference to a meter connected to the outgoing KR circuit.

Gauges: 2.5mm & 4mm detection gauge (RCPL) 3.5mm & 5mm detection gauge (IBCL) 1.5mm & 2mm micro-switch gauges.

1. Lock & Detection Setting

1.1 Close & lock the switch rail.

1.2 **Mk 2 Only:** Slacken the detector locking nut by 1/16th turn and turn the adjusting screw clockwise until the adjustable cam has reached the head of the adjusting screw.

1.3 **Mk 3 Only:** Slacken the detector locking nut by 1/16th turn. There is an additional inner lock nut on the adjusting screw (plain half nut). The inner nut (plain half-nut) shall be slackened sufficiently to allow the adjuster screw to move. Turn the adjusting screw clockwise until the adjuster screw head meets the detector blade lug.

Figure 1 - RCPL and IBCL (with Mk 2 clamp lock) Adjusting Screw field side

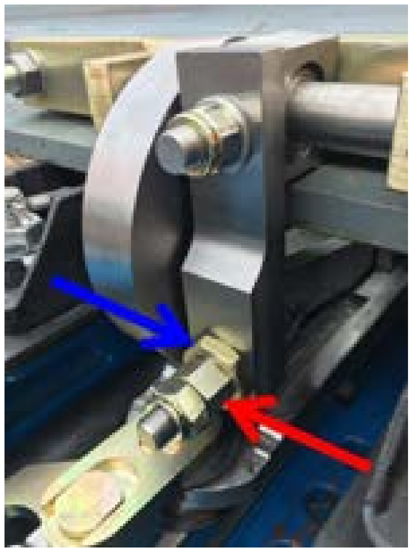

Figure 2 - IBCL Mk 3 Adjusting Screw (red). Inner lock-nut (blue). Adjustment made from 4' side

NOTE: *RCPL and IBCL (with Mk2 Clamp Lock) adjusting screws are found on the field side of the lock body. IBCL Mk3 adjusting screws are found on the 4ft side of the lock body. See Figure 1 and Figure 2 for details.*

1.4 Check the correct voltage is present on the outgoing KR circuit for the mechanism being tested.

1.5 Insert the 2mm gauge between the micro-switch plunger and the cam follower tappet screw.

1.6 Adjust the left-hand tappet screw until detection is broken; tighten the lock nut.

1.7 Retest the detection using the 1.5mm gauge. If necessary, adjust the left-hand tappet screw until detection is made. Tighten the lock nut.

Where adjustments are made to the left-hand tappet screw, repeat 1.1 to 1.7.

RCPL Only

1.8 Insert the 4mm gauge between the point detector blade lug and the shoulder of the connecting eye. Whilst observing the meter, turn the adjusting screw anticlockwise until the detection is just broken.

1.9 Tighten the nut and observe that the detection is broken. If detection is made, return to step 1.1.

Repeat using the 2.5mm gauge and observe the detection is made and the correct voltage is present on the KR circuit. If the detection is broken, remove the gauge and return to step 1.1.

IBCL Only

1.10 Insert the 5mm gauge between the point detector blade lug and the shoulder of the connecting eye.

NOTE: *On IBCL Mk 3, pull the bottom of the detector blade lug toward the 4' to open a gap for the 5mm gauge. When loosening or tightening the connecting eye nut retain the connecting eye with a spanner to prevent rotation of the spherical bearing.*

1.11 Whilst observing the meter, turn the adjusting screw anticlockwise until the detection is just broken.

1.12 Tighten nut and observe that the detection is broken. If detection is made, return to step 1.1.

1.13 Repeat using the 3.5mm gauge and observe the detection is made and the correct voltage is present on the KR circuit. If the detection is broken, remove the gauge and return to step 1.1.

1.14 Remove the gauge, tighten the nut and check that detection is made.

All Types

1.15 Insert the 1.5mm gauge between the left hand micro-switch plunger and the cam follower tappet screw. Observe the detection is made and the correct voltage is present on the KR circuit.

1.16 Repeat using the 2mm gauge and observe that detection is broken.

1.17 Remove gauge and open the closed switch rail to approximately 25mm (1”).

1.18 Observe that the right-hand tappet screw is level with the left-hand tappet screw. Adjust the right-hand tappet screw as necessary and tighten the lock nut.

1.19 Check, with the switch rail fully open, that there is a gap between the right-hand micro-switch plunger and its tappet screw.

1.20 Once adjustments have been correctly set, tighten lock nuts to specification.

NOTE: *On IBCL Mk 3 are two lock nuts to tighten, one on the end of the adjuster screw and another against the detector blade lug.*

1.21 Repeat steps 1.1 to 1.20 for the opposite switch position.

1.22 Carry out Facing Point Lock Test (Clamp Lock) – NR/SMS/PARTB/003

1.23 Request the Signaller to operate the points to normal and reverse positions (twice if possible). Observe correct operation.

END

Includes:	Rail Clamp Point lock (RCPL) & In-Bearer Clamp Lock (IBCL)
Excludes:	All other "Tests for Air" in Hydraulic Systems

1. Check a System for Air

1.1 Check the following:

a) The hydraulic fluid level in the reservoir.

b) The power pack is reasonably level.

c) The hose run does not have any major humps that can trap air.

NOTE: *Ideally, the hoses should rise slightly towards the power pack.*

1.2 Switch the Power Pack to 'Manual'.

1.3 Observe the lie of the points and move the direction control lever to the opposite lie.

1.4 Using the hand pump, gently pump until the drive mechanism just starts to move.

(In POCV fitted packs, a sudden release of pressure may be noticed).

1.5 Allow the direction control lever to return to the central position.

1.6 Using a crow bar:

RCPL & IBCL Mk 2:	Against the tie bar lugs, attempt to bar the points open.
IBCL Mk 3:	Against the open rail barring lug, attempt to bar the drive lock slide closed. It should not be possible to move the mechanism any measurable distance. Do not bar the switch rail itself.

1.7 The actuator piston should not move. If movement does occur, note how much and whether it springs back once released and refer to Table 1 regarding the action to be taken.

Movement	Likely Cause	Action
No measurable movement	Points free from trapped air.	No action required.
Some movement, spongy, mechanism springs back when released:	Some trapped air. (Expansion of long non-conductive hoses may result in some movement.)	Bleed the system and retest.
Movement with little resistance, mechanism does not spring back:	Internal leakage likely, possibly an over length POCV piston or piston head seal failure	Arrange to replace the power pack or ram as necessary. (This is not mandatory at a supplementary drive driven by a four-port power pack).

Table 1 – Results

1.8 Hand pump the points to the opposite position and repeat 1.6.

1.9 For installations fitted with traditional hydraulic supplementary drives (back drives) fed by four port packs, the tests shall be repeated at each drive point. Barring should be carried out at the closed switch rail.

1.10 When testing is completed, restore power operation.

2. Bleeding the System

2.1 Starting at the actuator, for each joint in turn, loosen the joint and hand pump fluid into the joint. When fluid flows without frothing, tighten that joint. Fit the locking wires.

2.2 Hand pump the points over and back again.

2.3 Operate the points, on power, normal and reverse for at least 6 complete cycles.

2.4 Test the system for air.

3. Installing a New Actuator

3.1 Refer to the relevant sections in the Clamp Lock Installation Manual suite for instructions, See table 2.

Clamp Lock Variant	S&C Design	Switch Opening	Supplementary Drive	Document Number
RCPL	CEN56 Full-Depth / UIC54 Shallow Depth	110	Mechanical	SRB0201ra
IBCL Mk 2	NR60 Mk 1	110	Mechanical / Hy-Drive	SRA0101ra
	NR56v	110	Mechanical / Hy-Drive	SRC0301ra
IBCL Mk 3	NR60 Mk 2	130	Mechanical	E05-01RA-1
		110	Hy-Drive	F06-01RA-1
	NR56v	110	Hy-Drive	G06-01RA-1
		110	Mechanical	H06-1RA-1

Table 2 – Document References

END

Isolate the supply to the point machine and operate points manually. Disconnect the point detection from the KR lines or apply an alternative safe system of work See NR/SMS/PartA/A04 (Method Statement Summary).

The positions and number of supplementary detectors can vary on switches of the same type from different manufacturers; in addition, the length of the turn out and the rail profile will affect the pass/fail criteria of the detector.

This means that with the position of the detector(s) and rail profile on certain combinations of switch layout, they will not always gauge to that stated in the test. An obstruction fail gauge lower than that stated is on the safe side.

In all circumstances, the obstruction pass/fail gauge shall NOT exceed the limits stated. If in doubt, ask your SM(S).

Tools and Gauges

- Detection Gauges (various depending on layout).
- Digital Volt Meter (DVM).
- Tape measure or rule.

1. Gauge Test (All detectors except those fitted to T72 style point machines)

1.1 Check that the points are locked REVERSE.

1.2 Disconnect the point detection from the KR lines or apply an alternative safe system of work. On Invensys Rail Westrace modular plug coupled points, the point detection shall be disconnected by uncoupling the 4c detection cable in the OC(P).

1.3 Check using the DVM that the correct voltage is present on the outgoing detection circuit (reverse detection).

On Invensys Rail Westrace modular plug coupled points, the correct voltage is a pulsing pseudo random voltage. This shall be checked for its presence at the first set of incoming terminals on which the detection supply cable is connected. Refer to site installation drawings.

1.4 Insert an 8mm gauge between the switch rail and stock rail at a point in line with the stretcher at the supplementary detector.

1.5 Manually operate and lock the points NORMAL.

1.6 Check normal detection is broken.

1.7 Repeat 1.3 to 1.6 using an 6mm gauge and Check that detection remains made.

1.8 Repeat 1.3 to 1.7 for the opposite lie of the points (reverse detection).

If any adjustments are made, the test shall be repeated.

1.9 Hand operate and lock the points REVERSE. Check reverse detection is made.

1.10 Repeat 1.1 to 1.9 for any other supplementary detectors in the layout.

1.11 Reconnect the points and Observe correct operation from the controlling point.

2. Gauge Test (Detectors fitted to T72 style point machines only)

2.1 Disconnect the detection at the junction box by removing links T1 number 1 and T1 number 3.

2.2 Remove the lineside detection disconnection box cover.

2.3 Connect a suitable meter, set to the ohms range, to the appropriate detection circuit terminals.

- If the left-hand switch blade is closed and locked: use T3 Link number 1 'B' side (LHS) and test point on T2 Link 4.
- If the right-hand switch blade is closed and locked: use T1 Link number 1 'B' side (LHS) and test point on T2 Link 4.

2.4 Measure the resistance (approximately 33kΩ).

2.5 Manually operate the switch blade to enable a 6mm gauge to be inserted between the switch rail and stock rail at a point in line with the stretcher at the supplementary detector.

2.6 Manually operate the switch blade onto the gauge.

2.7 Measure the resistance (approximately 33kΩ).

2.8 Manually operate the switch blade to enable an 8mm gauge to be inserted between the switch rail and stock rail at a point in line with the stretcher at the supplementary detector.

2.9 Manually operate the switch blade onto the gauge and Measure the resistance. This should be infinity.

2.10 Move the points to the opposite lie and repeat steps 2.3 to 2.10.

2.11 When the test has been completed for the lie of the point's normal and reverse, replace the lineside detection disconnection box cover.

2.12 Replace links T1 number 1 and T1 number 3 and Observe correct operation from the controlling point.

END

Includes:	Mk.1 Rail Clamp Point Locks
Excludes:	All other types of Clamplock

Where gas type point heaters are fitted, the gas supply shall be turned off.

Allow heated points to cool before the test is carried out.

1. Dye Penetrate Test

1.1 Clean the lock body and allow to dry.

1.2 Spray the “dye penetrate” in an even film over the area to be tested from a distance of 300mm.

1.3 Wait for 10 minutes to enable complete penetration of any cracks.

1.4 Wipe all excess dye from the surface using paper tissue moistened with cleaner until all red coloration has been removed from the surface.

1.5 Spray the developer in an even film over the area to be tested.

1.6 Wait 10 minutes for the developer to react with any remaining dye.

1.7 Report any signs of cracking (red lines) to your SM(S) immediately.

2. Eddy Current Test

2.1 Use the eddy current detector meter in accordance with the instruction manual.

2.2 Report any signs of cracking to your SM(S) immediately.

End

Gauges: 3.5mm/5mm point checking gauge
1.5mm gauge.

1. Detection Test

For each position of the points:

1.1 Place a 3.5mm point checking gauge between the switch and stock rails at a point in line with first slide chair bolt. Observe that the detection is broken.

1.2 Repeat the test using a 1.5mm gauge. Observe that detection is made.

1.3 Record the results on the test record card.

End

Voltage Test (Excluding Reed, SSI and Invensys Rail Westrace SOM24 fed points)

With 4 ends of points and supplementary detection, you should expect a volt drop under 2.0V. If you find a volt drop greater than expected, you should isolate the cause with the resistance test.

1.1 Check all point ends are in correspondence.

1.2 Compare the voltage at the detection circuit fuse with the voltage at the incoming detection circuit links or at the relay coil.

1.3 Repeat the test for the opposite lie.

1.4 Record the results on the record card.

2. Resistance Test

50/0.25mm cable has a typical al resistance of approximately 8 Ω/km, therefore a typical 200m tail cable circuit (out & back) should give a resistance of approximately 1.6Ω. This should be added to the resistance of circuit components and judgment applied.

Investigate the cause of any high resistance and action as a corrective maintenance item (e.g. high resistance contacts, poor termination, and cable core resistance).

Any value above 10Ω indicates a potential failure.

2.1 Check all point ends are in correspondence.

2.2 Disconnect the detection circuit at the links adjacent to the detection relay.

On Invensys Rail Westrace modular plug coupled points, the point detection shall be disconnected by uncoupling the 4c detection cable in the OC(P)

2.3 Connect a multi-meter and Measure the resistance through each leg of the point detection circuit from the fuse/ terminal to the relay link. Tap the micro-switches and look for any light contacts.

2.4 Repeat the test for the opposite lie of points.

2.5 Reconnect the detection circuit and Observe correct operation of the points.

End

Includes:	Hydraulic Derailers (Type BRB 817) powered by SPX Hydraulic Pumps and Actuators.
Excludes:	All other types of Derailer.

The equipment shall not be operated on power until the unit has been proven to work correctly by hand pump operation.

Hydraulic Derailers use a standard Clamplock pump unit and a pair of Clamplock rams to drive a Derailer mechanism. Detection is accomplished using a standard circuit Controller or a 998 unit

Tests

1. Mechanical Set-up and Test

1.1 With the Derailer in its normal position (on rail) Check that the sleeper to sleeper dimension (Inside edge to inside edge) is 575mm

1.2 Check that the Derailer Rail Unit flange cut out aligns with the running edge of the rail.

1.3 Check that the Derailer Rail Unit is in contact with the rail when in the ‘Normal’ position.

1.4 Check that the Derailer Rail Unit is in contact with the Derailer stop when in the ‘Reverse’ position. In accordance with Drawing SE-SK-0415

1.5 Check the torque settings of the nuts for the bolts holding the Derailer mechanism to the rail at 80Nm.

1.6 Check the Derailer Drive Rod Alignment to the Driving Crank is parallel and in line to adjacent sleepers leading to the de-railer connection pin.

1.7 Check that when operated that the driving crank between the Hydraulic Pump Unit connecting rod, operates smoothly and that the driving angle does not become chocked or interferes with the Detector Box, and that the crank is greased and is fitted with respective grease nipples in the crank stud and joint pins.

2. Test Normal Detection

2.1 With the points on manual and with a meter connected to the detection lines check, that normal detection is made when the Derailer is in the 'Normal' position (in contact with the rail).

2.2 Move Derailer to off-rail position and check that 'Normal' detection is broken when the Derailer Rail Unit has moved by no greater than 2mm from the 'Normal' position i.e. no greater than 2mm between the rail surface and bottom of Derailer Rail Unit.

2.3 Move Derailer towards on-rail position and Check detection does not make until the Derailer is 2mm from the 'Normal' position i.e. no greater than 2mm between the rail surface and bottom of Derailer Rail Unit.

3. Motor Cut Out Test

3.1 Disconnect detection lines; Select 'Power' and ask the signaller to operate the Derailer. Check the overload cut-out operates (6-9 seconds) Reconnect detection after successful test.

4. Local Correspondence Test

4.1 Check that the KR Lines are disconnected before carrying out this test and that the signaller has been informed that indications for the De-railer will be lost.

4.2 Remove the pump unit cover and turn to "Power" before carrying out the following tests.

4.3 TEST the correspondence of all detection positions by the breaking of the Normal / Reverse detection contacts and observing the correct indication relays are operated. 50V shall be present on the NKR and 0V on the RKR for 'Normal' position. 50V shall be present on the RKR and 0V on the NKR for 'Reverse' position.

4.4 TEST the correspondence of all detection positions by the breaking of the Normal / Reverse detection contacts and observing that the correct detection at the signal box is lost.

5. Signal Box Correspondence Test

5.1 TEST that the signal box point switch, and any indication corresponds with the Derailer position for both 'Normal' and 'Reverse' positions.

5.2 TEST that a correct out of correspondence indication is present at the controlling signal box; with the Derailer in the 'Normal' position, key the points reverse and observe no movement of the Derailer. Confirm the out of correspondence indication with the signal box.

5.3 Using pump handle pump the Derailer into the 'Reverse' position and confirm correct indication in signal box.

5.4 TEST with the Derailer in the 'Reverse' position key the points 'Normal' and observe no movement of the Derailer. Confirm the out of correspondence indication with the signal box.

5.5 Using pump handle pump the Derailer into the 'Normal' position and confirm correct indication in signal box.

5.6 The final check before completion of the work is to ask the signaller to operate the Derailer to 'Normal' and 'Reverse' positions (3 times each way), while observing the movement of the Derailer is correct.

Specific Definitions

Term	Definition
Derailer Stop	Metal plate that protects rodding when Derailer Rail Unit is in reverse position.
Derailer Rail Unit	Derailing block that sits on top of rail.
BR817 Power Pack	Electro Hydraulic Power Pack that provided power to actuator.

End

General

Lamp voltage and current ranges are listed in NR/SMS/Part/Z01

A voltage below the specified range can result in insufficient light output conversely too high a voltage may affect the life of the lamp.

The notes following the types of lamp give more details. Where practicable every aspect should be tested once per year.

Lamps fed directly from 110V bus bars in most cases will not be able to be adjusted. Inform your SM(S) if a lamp fed directly in this way is out of the stated limits.

Quartz Halogen Lamps

Signals using these have separate lamps for the main and auxiliary.

Check these lamps are set to run as close as possible to their rated voltage. If this is not possible, report it to your SM(S) immediately.

Running a Quartz Halogen lamp at a voltage lower than its rated voltage will cause the glass envelope to blacken and consequently the light output will be reduced.

These lamps become very hot "do not" touch the glass with your bare hands.

If this occurs the glass should be cleaned with methylated spirits.

Automatic Signals

Aspects are tested using one of the following methods:

- Disconnection of the circuits to the controlling relay
- Following passage of a train.

Ansaldo SD321 Signals

The lamp / lamp holder metal components can be very hot.

Before refitting the lamp / lamp holder assembly, the red notches on the lamp holder and optical unit shall be aligned to confirm polarisation.

Because of the configuration of these signals, the lamp voltage and lamp proving tests are combined in this test. This does not apply to Position Light Junction Indicator (PLJI) and Ground Position Light (GPL) lamp proving which are contained in NR/SMS/Test/022.

The signal lamp voltage and proving tests requires the use of the Ansaldo Maintenance Terminal and shall only be performed with the agreement of the signaller.

These tests shall not be performed if a train is approaching as this may cause the signal to display a red aspect.

Every aspect shall be tested once per year as a minimum. Each lamp shall be illuminated and tested in turn.

Signal lamp voltages are recorded at the maintenance desk and on the signal head record card kept in the signal head.

If the voltage cannot be maintained within the voltage range detailed in NR/SMS/Part/Z01, report the problem to your SM(S) immediately.

If the voltage on an unlit lamp is found to be ≥0.8V, the actions detailed in NR/SMS/Appendix/02 shall be followed and your SM(S) informed immediately.

1. Voltage Test (Not Quartz Halogen Lamps)

1.1 Measure the main filament voltage for each signal aspect and Check (where provided) for 0V on the auxiliary filament. Voltages are listed in NR/SMS/Part/Z01

A standing voltage on the auxiliary filament terminals indicates a problem with the filament proving circuitry.

On SIMIS-W schemes, measure the main filament voltage for each signal aspect across the appropriate Wago terminals.

1.2 Disconnect the main filament and Measure the auxiliary filament voltage (where provided) for each aspect.

On SIMIS-W schemes, disconnection of the main filament is achieved at the Wago terminals for the appropriate aspect under test.

After the test, check that the Wago terminal is fully inserted in to its original position.

1.3 Record the results on the signal lamp record card. Where illumination of a lamp is refused by the signaller, endorse the record card ‘REFUSED’.

2. Voltage Test (Quartz Halogen Lamps Only)

Some banner repeater signals have two main lamps illuminated simultaneously; therefore the tests applicable to auxiliary lamps do not apply. If you are in doubt, ask your SM(S).

2.1 Measure the main lamp voltage and Check for 0V on the auxiliary lamp.

A standing voltage on the auxiliary lamp terminals indicates a problem with the filament proving circuitry.

2.2 Disconnect the main lamp and Measure the voltage on the auxiliary lamp.

2.3 Record the results on the signal lamp record card. Where illumination of a lamp is refused by the signaller, endorse the record card 'REFUSED'

3. Current Test (SIMIS-W Interlocking Areas Only)

3.1 Measure, using a suitable current clamp meter, the current on the primary side of the transformer. Currents are listed in NR/SMS/Part/Z01

4. Voltage Test & Proving Test (Ansaldo SD321 Signal)

For the lower optical unit:

4.1 Arrange for a red aspect to be displayed.

This should be displayed in the lower aperture.

4.2 Measure the voltage of the illuminated lamp.

4.3 Measure the voltage of the unlit lamps. See the notes in the general section

4.4 Remove the illuminated lamp/lamp holder assembly and Check that the filament failure alarm has operated. Use the Ansaldo Maintenance Terminal.

4.5 Check that the corresponding auxiliary aspect lamp illuminates in the upper optical unit.

4.6 Measure the voltage of the unlit lamps in the upper optical unit.

See the notes in the general section

4.7 Replace the lamp/lamp holder assembly.

4.8 Re-instate the lamp as the operative lamp. This is a Signaller action.

4.9 Check that the operative lamp is illuminated and that the corresponding auxiliary aspect lamp is extinguished.

4.10 Repeat 4.2 to 4.9 for the yellow aspect.

For the upper optical unit:

4.11 Arrange for a green aspect to be displayed.

This should be displayed in the upper aperture.

4.12 Measure the voltage of the illuminated lamp.

4.13 Measure the voltage of the unlit lamps. See the notes in the general section.

4.14 Remove the illuminated lamp/lamp holder assembly and Check the filament failure alarm has operated. Use the Ansaldo Maintenance Terminal.

4.15 Check that the corresponding auxiliary aspect lamp illuminates in the lower optical unit.

4.16 Measure the voltage of the unlit lamps in the lower optical unit.

4.17 Replace the lamp/lamp holder assembly.

4.18 Re-instate the lamp as the operative lamp (this is a Signaller action).

4.19 Check that the lamp is illuminated and that the auxiliary lamp is extinguished.

4.20 Repeat 4.12 to 4.19 for the yellow aspect.

End

GENERAL

There are no record cards for these tests, however where a route cannot be set to prove an aspect, junction indication or route indication, report this on your work order.

Computer Based Interlocking (CBI) Areas

In CBI areas the lamp proving function can be checked by use of the data link interrogator, the Technician's terminal or by asking the Signaller to observe their panel indications.

SIMIS-W Areas

In SIMIS-W areas, the S&D terminal is used to check the operation of the failure alarm. The S&D terminal and the Vicos terminals are used to check that the operation of the lamp proving function.

1. Multi Aspect Signals on CBI Areas (Filament Lamps)

1.1 Remove the lamp from lamp holder.

1.2 Check the lamp proving function has operated.

1.3 Replace the lamp.

1.4 Disable the main filament.

1.5 Check that the main filament is extinguished and the auxiliary filament illuminates.

1.6 Check the filament failure alarm has operated.

1.7 Reconnect the main filament.

1.8 Check that the auxiliary filament extinguishes and the main filament illuminates.

2. FOCL Signals on CBI Areas

2.1 Remove the flying leads of the main and auxiliary QH lamps.

2.2 Check that an alarm has been raised.

2.3 Connect the flying leads of the main and auxiliary QH lamps and check the main QH lamp is illuminated only.

2.4 Remove the flying lead to the main QH lamp and check the auxiliary QH lamp illuminates.

2.5 Check that an alarm has been raised.

2.6 Connect the flying lead to the main QH lamp and check that the main QH lamp illuminates and the auxiliary lamp extinguishes.

3. Multi Aspect Signals on Non-CBI Areas (Filament Lamps)

3.1 Remove the lamp from lamp holder.

3.2 Check the lamp-proving relay de-energises.

3.3 Replace the lamp.

3.4 Check the lamp-proving relay re-energises.

3.5 Disable the main filament.

3.6 Check that the main filament is extinguished and the auxiliary filament illuminates.

3.7 Check the filament failure alarm has operated.

3.8 Reconnect the main filament.

3.9 Check that the auxiliary filament extinguishes and the main filament illuminates.

4. Multi Aspect Signals on SIMS-W Areas (Filament Lamps)

4.1 Using the disconnection links in the signal head disable the main filament.

4.2 Check that the main filament is extinguished and the auxiliary filament illuminates.

4.3 Check the filament failure alarm has operated.

4.4 Using the disconnection links in the signal head disable the auxiliary filament.

4.5 Check the lamp proving function has operated.

4.6 Reconnect the auxiliary filament.

4.7 Check that the main filament is extinguished and the auxiliary filament illuminates.

4.8 Check the lamp proving function has operated.

4.9 Reconnect the main filament.

4.10 Check that the auxiliary filament extinguishes and the main filament illuminates.

4.11 Check the filament failure alarm shows rectified.

5. FOCL Signals on SIMIS-W Areas

5.1 Carry out these steps for each lamp in turn:

a) Using the disconnection links in the signal head disconnect the QH lamp.

b) Check that an alarm has been raised.

c) Reconnect the QH lamp.

d) Check the lamp failure alarm shows rectified.

6. LED Multi Aspect, Position Light, and Route Indicators (Dorman Light Modules Only)

NOTE: *Excluding areas fed by the Invensys Rail Westrace SOM24. See Section 15.*

6.1 Check drawings as some LED PLS are not lamp proved.

6.2 Disconnect the link to the light module under test. Liaise with the Signaller to obtain the required aspect/indication.

6.3 Check that the lamp-proving relay de-energises. On CBI areas check that an alarm is raised.

6.4 Reconnect the link to the module and check that the lamp-proving relay re-energises.

6.5 Check that the correct aspect/indication is displayed.

7. Fibre Optic Position Light Signals

7.1 Disconnect the link feeding the main QH lamp.

7.2 Check that the auxiliary QH lamp illuminates.

7.3 If lamp-proving indication is provided in the controlling signal box, check that the correct indications are given.

7.4 Reconnect the link feeding the main QH lamp. Check it illuminates and the auxiliary QH lamp extinguishes.

8. Mechanical Signals using a Paraffin Lamp and Pyrometer

8.1 Open the outer lamp case and allow the pyrometer to cool.

8.2 Check the Signaller receives a “lamp out” warning/indication. Check when the audible is cancelled the indication remains.

8.3 Close the cover and check that once the pyrometer has heated up, the audible sounds. Check when cancelled, the audible ceases and the indication restores.

9. Mechanical Signals using Electric Lamps

9.1 Disconnect the link feeding the lamp.

9.2 Check the lamp-proving relay de-energises and the correct indication is given in the controlling signal box.

9.3 Reconnect the link feed the lamp. Check it illuminates and the lamp-proving relay re-energises.

10. Junction Indicators with Five Lamps (Filament Lamps, not SIMIS-W Interlockings)

10.1 Arrange with the Signaller to display an agreed route indication. Check the indication is displayed and the main signal shows a proceed aspect.

10.2 Remove lamps until only two are illuminated.

10.3 Check the lamp-proving relay de-energises and the main signal shows a red aspect. On CBI areas check that an alarm has been raised.

If these checks fail, with only two lamps remaining fitted, have the Junction Indicator extinguished and re-illuminated. Repeat the checks.

10.4 Replace one lamp.

10.5 Check the lamp-proving relay re-energises and the main signal shows a proceed aspect.

10.6 It might be necessary to extinguish and re-illuminate the indicator.

10.7 Replace the remaining lamps.

10.8 Check that all lamps are illuminated.

10.9 Repeat steps 10.1 to 10.7 for each available route indication at the signal.

11. Junction Indicators with Five Lamps (Filament Lamps, SIMIS-W Interlockings Only)

11.1 Arrange with the Signaller to display an agreed route indication. Check the indication is displayed and the main signal shows a proceed aspect.

11.2 Remove each lamp in turn.

11.3 Check the relevant alarm message has been received on the diagnostic terminal.

11.4 Replace the lamp.

11.5 Repeat 11.2 to 11.4 for all remaining lamps.

11.6 Check all lamps are illuminating.

11.7 Repeat 11.2 to 11.4 for each route indication at the signal.

12. Junction Indicators fitted with Five Dorman LED Light Modules

NOTE: *This task might not be possible in Plug and Plug Area.*

12.1 Arrange with the Signaller to display an agreed route indication. Check the indication is displayed and the main signal shows a proceed aspect.

12.2 Disconnect the links to the modules until only two are illuminated.

12.3 Check the lamp-proving relay de-energises and the main signal shows a red aspect.

On CBI areas check that an alarm is raised.

12.4 Reconnect the link to one module.

12.5 Check the lamp-proving relay re-energises and the main signal shows a proceed aspect.

12.6 Reconnect the remaining links.

12.7 Check that all the light modules are illuminated.

12.8 Repeat items 12.1 to 12.7 for each available route indication at the signal.

13. Ansaldo Five Lamp Position Light Junction Indicators

> ***NOTE:*** *The lamps are paired: 3 and 5, 2 and 4 and each pair is driven by a single POT. The pivot lamp (lamp 1) has its own POT, see NR/SMS/Appendix/02 (General Information on Ansaldo Signalling Equipment).*

13.1 Liaise with the Signaller before carrying out these tasks.

13.2 Arrange with the Signaller to display a proceed aspect with an agreed route indication.

13.3 Remove the pivot lamp and check that the signal is still showing a proceed aspect .

13.4 Remove one other lamp and check that the corresponding lamp in the pair extinguishes. The associated POT has shut down.

13.5 Check that the signal has reverted to RED.

13.6 Replace the lamps and request the Signaller to reset the signal and display the previously agreed proceed aspect with an agreed route indication.

13.7 Check that all the lamps are illuminated. The associated POTs have powered-up.

13.8 Remove one non-pivot lamp and check that the corresponding lamp in the pair extinguishes. The associated POT has shut down.

13.9 Remove one lamp from the other pair and check that the corresponding lamp extinguishes. The associated POT has shut down leaving only the pivot illuminated.

13.10 Check that the signal has reverted to a RED aspect.

13.11 Replace the lamps and request the Signaller to reset the signal and display the previously agreed precede aspect with an agreed route indication.

13.12 Check that all the lamps are illuminated, and the associated POTs have powered-up.

13.13 Repeat items 13.1 to 13.11 for each available route indication at the signal.

14. Ansaldo Ground Position Light Signal

14.1 Arrange with the Signaller to display an ON indication.

14.2 Check that the Main ON lamp is illuminated.

14.3 Remove the Main ON lamp and check that the Auxiliary ON lamp illuminates.

14.4 Replace the Main ON lamp and request the Signaller to re-set the signal.

14.5 Check that the Main ON lamp illuminates and that the Auxiliary ON lamp extinguishes.

14.6 Arrange with the Signaller to display an OFF indication.

14.7 Remove the OFF lamp and check that the signal is ‘black’, no aspect is displayed.

14.8 Check that the alarm is activated.

14.9 Replace the OFF lamp and request the Signaller to re-set the signal.

14.10 Check that the OFF lamp illuminates and that the alarm is silenced.

15. LED Multi Aspect, Position Light, and Route Indicators Invensys Rail Westrace SOM24 fed.

15.1 Check drawings as some LED PLS are not lamp proved.

15.2 Check that the relevant input LED on the SOM24 is illuminated indicating voltage free contact proving.

15.3 Disconnect the plug coupler in the OC or MEH to the signal or route indicator under test.

15.4 Liaise with the Signaller to obtain the required aspect/indication.

15.5 Check that the relevant input LED on the SOM24 extinguishes indicating no voltage free contact proving.

15.6 Reconnect the plug coupler in the OC or MEH to the signal or route indicator under test and check that the relevant input LED on the SOM24 illuminates indicating voltage free contact proving.

15.7 Check that the correct aspect/indication is displayed.

15.8 Check that the plug coupler is securely fitted, and its retaining clip is engaged fully.

END

1. Signal Post Replacement Switch (SPRS) Test

1.1 Check that the signal is displaying a proceed aspect.

1.2 Request permission from the Signaller to operate the signal post replacement switch.

1.3 Check, with the switch turned to ‘RED’, the signal returns to a red aspect.

1.4 Check, with the switch turned to ‘AUTO’, the signal displays a proceed aspect.

2. Signal Box ERS Test (Automatic Signals)

2.1 Check that the signal is displaying a proceed aspect.

2.2 Request the Signaller to operate the emergency replacement switch.

2.3 Check the signal returns to a red aspect.

2.4 Confirm the ‘signal at red’ indication is illuminated at the signal box.

2.5 Request the Signaller to restore the switch to the ‘AUTO’ position.

2.6 Check the signal displays a proceed aspect.

2.7 Confirm the ‘signal at red’ indication is extinguished at the signal box.

3. SPAD Indicator Test

3.1 Test the SPAD function by slipping the test link.

a) Observe the SPAD indicator illuminates.

b) Observe the Technicians test lamp is lit.

3.2 Check the following:

a) The flasher is operating.

b) The treadle is operating correctly.

c) The over-ride plunger has not stuck up.

d) The timer (SPAD GR) is correctly set.

3.3 Check that an alarm entry with a RED symbol is displayed in the relevant trackside object alarm window.

3.4 Acknowledge or remove the alarm condition and check that the audible alarm is silenced and that the symbol changes to YELLOW.

3.5 Check that the alarm and symbol display is cleared when the alarm has been resolved (when the track circuit in advance of the signal has cleared).

3.6 Return the signal (SPAD alarm) to service operation.

4. SPAD Alarm on Ansaldo Signals (Test 2)

4.1 Agree with the Signaller, the particular signal (SPAD alarm) to be tested and simulate a SPAD situation.

NOTE: *This can be achieved by operating the relevant track circuits on the maintainers' desk.*

4.2 Check the associated audible alarm activates immediately and an alarm entry with a RED symbol is displayed in the relevant trackside object alarm window.

4.3 Resolve the alarm (without acknowledgement). Clear the track circuit in advance of the signal.

4.4 Check the alarm has self-restored and that the symbol has changed to GREEN.

4.5 Return the signal (SPAD alarm) to service operation.

5. SPAD Alarm on Ansaldo Signals (Test 3)

5.1 Agree with the Signaller, the particular signal (SPAD alarm) to be tested and simulate a multiple SPAD situation.

NOTE: *This can be achieved by operating the relevant track circuits on the maintainers' desk.*

5.2 Check that the associated audible alarms activate immediately and that the volume and/or tone of the audible alarm is distinctive, dissimilar, and acceptable to the Signaller. Arrange adjustment with your SM(S).

5.3 Check an alarm entry with a RED symbol is displayed in each relevant trackside object alarm window.

5.4 Check that acknowledgement silences all the audible alarms and that each symbol only changes to YELLOW when its associated alarm entry is acknowledged.

5.5 Check that each alarm and symbol display is only cleared when its associated alarm has been resolved (when the track circuit in advance of the particular signal has cleared).

5.6 Return the signals (SPAD alarms) to service operation.

6. Flasher Unit Test (Flashing Aspects)

6.1 To avoid interference with signal aspect sequences and relay stick circuits, the TEST and RESET buttons shall only be operated under the following conditions:

a) Check the four flasher unit indication lamps are extinguished.

b) Check the flasher unit proving relay (FECR) is de- energised.

SIGNALS CAPABLE OF DISPLAYING A FLASHING DOUBLE YELLOW ASPECT:

6.2 With the signal at danger and the first track circuit ahead of the signal occupied:

a) Press the TEST button, check the four indication lamps are lit and the FECR is de-energised.

b) Press the RESET button, check the four indication lamps extinguish and the FECR re-energises.

SIGNALS CAPABLE OF DISPLAYING A FLASHING SINGLE YELLOW ASPECT:

6.3 With the signal not displaying a flashing aspect:

a) Press the TEST button, check the four indication lamps are lit and the FECR is de-energised.

b) Press the RESET button, check the four indication lamps extinguish and the FECR re-energises.

END

General

Standard strength inductors are coloured yellow and can operate at 12VDC, 24VDC and 110VAC.

On lines employing third or fourth rail DC traction, extra strength inductors are used, which are coloured green these can also operate at 12VDC, 24VDC, 60VDC, 100/110VDC or 110VAC.

Corresponding yellow and green S&P meters are available for testing each type.

When testing yellow magnets, the yellow S&P meter shall be placed upright in the centre of the top surface of the magnet. When testing green magnets, the green S&P meter shall be stood on a 46mm wooden plinth upright in the centre of the top surface of the magnet. This applies to both permanent magnets and electro-magnets.

Some AWS Inductors can be wired for parallel or series operation check the local diagrams for details.

Inductors can be fitted with plug couplers and if they are provided, voltage and current measurements shall be taken at the inductor by the use of an approved “breakout” connector.

If a Vortok Electro-Magnet or Suppressor Magnet is being tested, there is not a controlling relay to check, depending on the type of interlocking/trackside equipment in use. Contact the Signaller and arrange for the routes to be set to energise/de-energise the magnets during the tests.

NOTE: *The Vortok AWS magnets are designed with spark quench diodes as part of the internal circuitry and there is no requirement to perform this test.*

1. Permanent Magnet

1.1 Test permanent magnet flux strength using the S&P meter.

The pointer should move to the green position, with the letter ‘P’ displayed.

If the pointer only moves to the yellow position with a letter ‘P’, the magnet shall be replaced as soon as possible.

If the pointer remains in the red position, the magnet shall be reported as a failure to the Signaller as this can lead to a wrong side failure.

2. Electro-Magnet

2.1 Test electro-inductor flux strength using the S&P meter for caution and proceed signal aspects or positions.

Check that the inductor remains de-energised for R, Y & YY signal aspects (and distant arm ON). The pointer should remain in the red position.

For a green aspect (or distant arm OFF), the pointer should move to the green position, with the letter ‘E’ displayed.

If the pointer only moves to the yellow position with a letter ‘E’, the magnet shall be replaced as soon as possible.

If the pointer remains in the red position, the magnet shall be reported as a failure to the Signaller and as a corrective maintenance item.

2.2 At the electro-inductor terminals Measure the electro-inductor voltage for both caution and proceed signal aspects. A “breakout box” shall be used if required.

Check that 0v is present for R, Y & YY aspects (or distant arm ON). Check that the energised voltage is within 10% of nominal voltage. Voltages are detailed in NR/SMS/Part/Z08 (Train Protection - Reference Values).

2.3 Measure the electro-inductor current for green aspects (and distant arm OFF). A “breakout box” shall be used if required.

3. Suppressor Magnet

3.1 At the inductor terminals measure the suppressor inductor voltage. A “breakout box” shall be used if required.

Voltages are detailed in NR/SMS/Part/Z08 (Train Protection - Reference Values).

A suppressed inductor can be energised by requesting the Signaller to set a route over the inductor in the opposite direction to that for which the de-energised inductor is used. It might be necessary to drop the track circuit over the inductor, as power saving controls are sometimes used.

3.2 Test suppressor flux strength using the S&P meter.

a) Check the controlling relay is energised, or if no relay present, check the controlling equipment is driving the suppressor magnet. The permanent magnet should be suppressed.

b) Test suppressor flux strength using the S&P meter.

The pointer should remain in the red position.

c) Check the controlling relay is de-energised, or if no relay present, check the controlling equipment is not driving the suppressor magnet. The permanent magnet should not be suppressed.

d) Test suppressor flux strength using the S&P meter.

The pointer should move to the green position, with the letter ‘P’ displayed.

The permanent magnet field should be present (see Section 1).

3.3 Measure the current flow through the inductor.

a) Check the controlling relay is energised, or if no relay present, check the controlling equipment is driving the suppressor magnet. The permanent magnet should be suppressed.

b) Test the current flow through the suppressor.

The suppressor magnet should be energised, and the permanent magnet should be suppressed. The meter should measure current flowing.

c) Check the controlling relay is de-energised, or if no relay present, check the controlling equipment is not driving the suppressor magnet. The permanent magnet should not be suppressed.

d) Test the current flow through the suppressor.

The permanent magnet field should be present and there should be no current flowing.

4. Records

4.1 Record all the results on the record card.

5. Spark Quench

Where an external spark quench diode is present and during a fault investigation carrying out this test might assist with the fault diagnosis.

a) Disconnect one leg and test the diode or resistor spark quench.

On electronic meters the diode test function should be used to test the spark quench diode (audible beep one way, nothing on the other).

If you are using an analogue meter, the resistance range should be used (low, typically 100Ω one way and high, typically several thousand the other).

The spark quench resistor should be tested using the resistance range on both types of meter. Resistor values should correspond with the diagrams.

b) Reconnect the disconnected leg.

END

Includes:	Vehicle Identification System used in the Sheffield Tram-Train Project Network Rail mainline infrastructure, between the Sheffield Supertram network and Parkgate Tram Stop.
Excludes:	Vehicle Identification System used on the Sheffield Supertram Network

GENERAL

The following process should be used when a particular loop requires replacement or reactive maintenance.

The process explains how to tune the loop to the 147 kHz frequency providing the maximum signal strength at the loop, by adjustment of the Tuner Unit links.

1. Loop Tuning Setup

1.1 Check the loop and feeder cables are connected and no links LK1 – LK10 are fitted.

1.2 Connect a test ribbon cable with the 10-way dip switch in test connector.

1.3 Check that the 10-way switch is switched OFF in reset condition.

1.4 Now connect the oscilloscope, loop test meter box or multi meter (capable of reading a high frequency) to the loop feeder cable in loop tuner unit.

1.5 The aim is to set the maximum reading by changing the switch position starting from switch 10 towards switch 1.

1.6 Switches 1-5 select a low capacitance, and these have very little effect, whereas switches 6-10 select higher values of capacitance and thus have a greater effect on the tuning.

1.7 Initially note down the loop voltage reading in the start condition.

1.8 Now turn ON switch 10 and make sure the corresponding reading is increased from the start condition. If it is increased, then switch 10 is kept set to the ON position.

1.9 If the reading is decreased from the start value, then turn switch 10 to the OFF position.

1.10 Now turn on switch 9. If it increases the output from the previous value then keep switch 9 on and now turn off switch 10 and check if the reading increases, if yes then turn off switch 10 and turn on switch 9 alone. If it decreases, then both switch 9 and 10 are kept on.

1.11 Repeat step 1.7. to 1.10 for all the switches positions from 8 to 1.

1.12 Note down the switch position that are ON and make sure the corresponding link headers in the Tuner Unit are fitted in the corresponding positions.

1.13 Remove the test ribbon cable and re-fit the Tuner Unit cover.

1.14 Any unused left-over link headers are stored for future use.

1.15 After completion of the tuning adjust the related Loop card potentiometer VR2 clockwise or anticlockwise to set the loop voltage to the level as per Table 1.

Rack Voltage			**Loop Tuner Feeder**			**Loop Tuner Loop**		
Fluke	**Meter Box**	**Oscilloscope**	**Fluke**	**Meter Box**	**Oscilloscope**	**Fluke**	**Meter Box**	**Oscilloscope**
3.7V	70	10V	3.6V	70	10V	7.5V	FSD	22.4V
3.7V	70	10V	3.7V	70	10V	8.1V	FSD	24V

Table 1 – Loop Voltages

1.16 Finally phase the loop and simulate trams using the tram simulator to make sure the loop is fully functional.

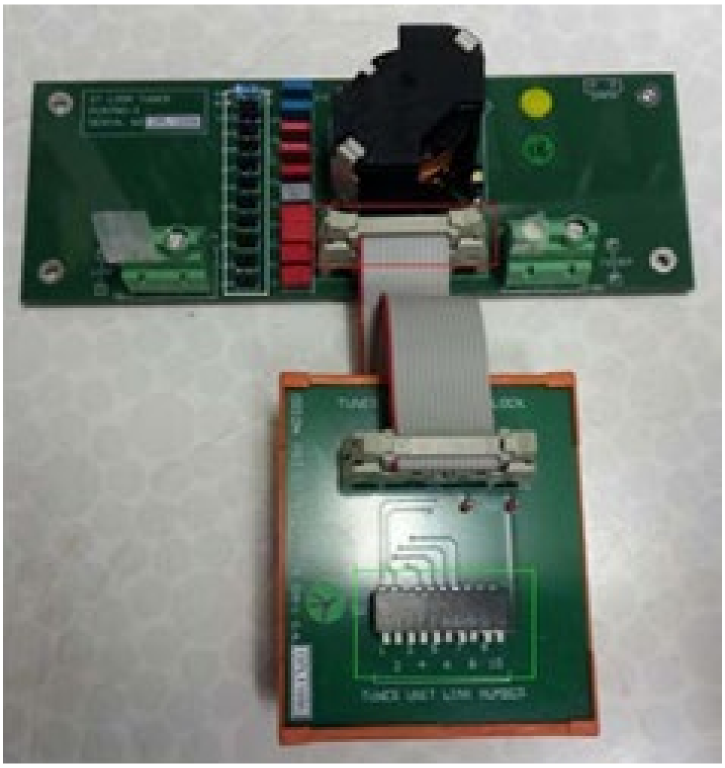

Figure 1 - Loop Tuner with 10-way DIP switch

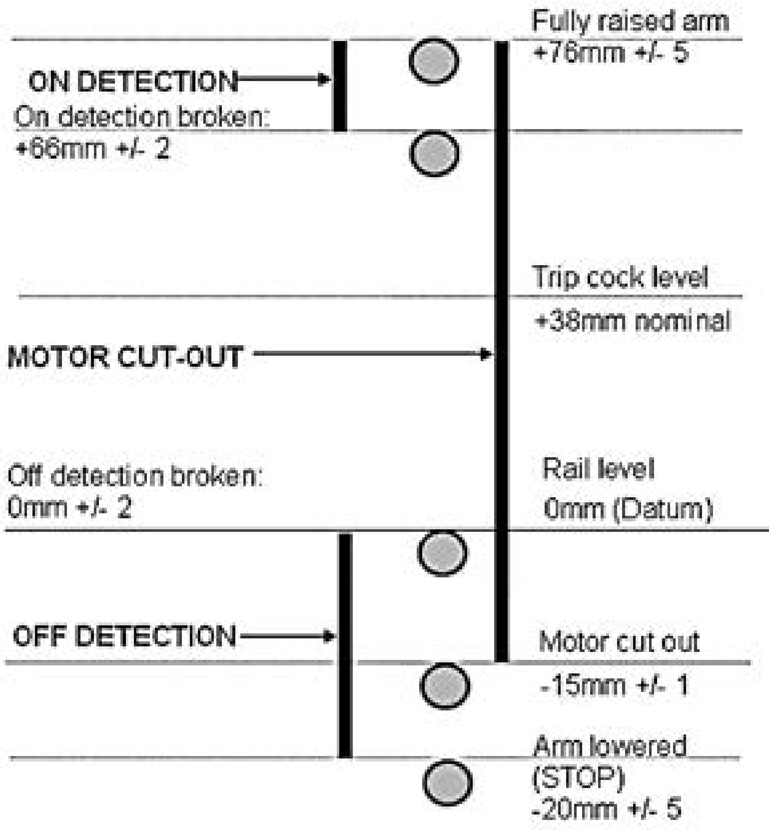
END

Includes:	Electro-hydraulic Trainstops
Excludes:	All other Trainstops

1. Test

1.1 Manually operate the trainstop and Check the following:

- With stop arm fully raised: 'ON' detection is made.
- 'ON' detection is lost when stop arm is depressed by 10mm (± 2mm).
- When stop arm is fully lowered, 'OFF' detection is made.
- 'OFF' detection is maintained from the fully lowered position until the stop arm is raised to rail level (± 2mm).
- Check that motor cut out contacts are set to break when stop arm is 5mm (± 1) above the fully lowered position.



End

Includes:	Siemens JE Trainstop.
Excludes:	All other types and styles of Trainstop .

Trainstops contain moving parts which can cause severe personal injury.

1. Trainstop Test

1.1 Check the tail cables, Earth Bond and power supply is reconnected.

1.2 Confirm with the signaller that the signal associated with the train stop is at danger and confirm what indication he/she has for the Trainstop.

1.3 Request the Signaller to clear the signal associated with the Trainstop to a proceed aspect.

1.4 Observe the trainstop moves completely to the lowered position.

1.5 Check that the motor cuts out prior to the Trip Arm hitting the lower stop.

1.6 Ask the Signaller to confirm the indication.

1.7 Request the Signaller to place the signal associated with the Trainstop back to danger.

1.8 Observe the trainstop moves completely to the raised position.

1.9 Ask the Signaller to confirm the indication.

End

JE Style Trainstop – Positioning Check

Issue No: 01	Issue Date: 03/03/18	Compliance Date: 31/05/18

Includes:	Siemens Style JE Trainstop.
Excludes:	All other types and styles of Trainstop .

Trainstops contain moving parts which can cause severe personal injury.

1 Positioning Check

1.1 Check the Trip Arm is the correct distance from the running rail.

The distance from the inside of the running rail to the centre of the Trip Arm must be 222 mm +/- 3mm, as shown in Figure 1. In areas with conductor rails a non-metallic rule shall be used.

If necessary slacken the Trainstop fixings and adjust the position of the Trainstop. If it is still not possible to set the correct distance:

- Suspect damage or distortion to the Trainstop.

Figure 1 – Distance from Rail

1.2 Using the Trip Arm Gauge, check the height of the top of the raised Trip Arm is 76 mm +/- 3 mm above a line joining the tops of the running rails (see Figure 2).

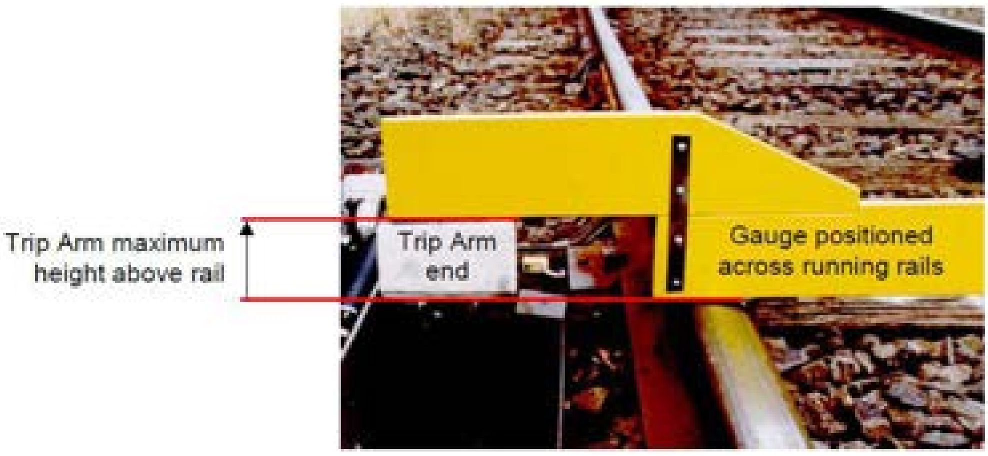


Figure 2 – Height of Trip Arm Checked with Gauge

1.3 If the height is out of tolerance, add or remove Packer Plates (Figure 3).

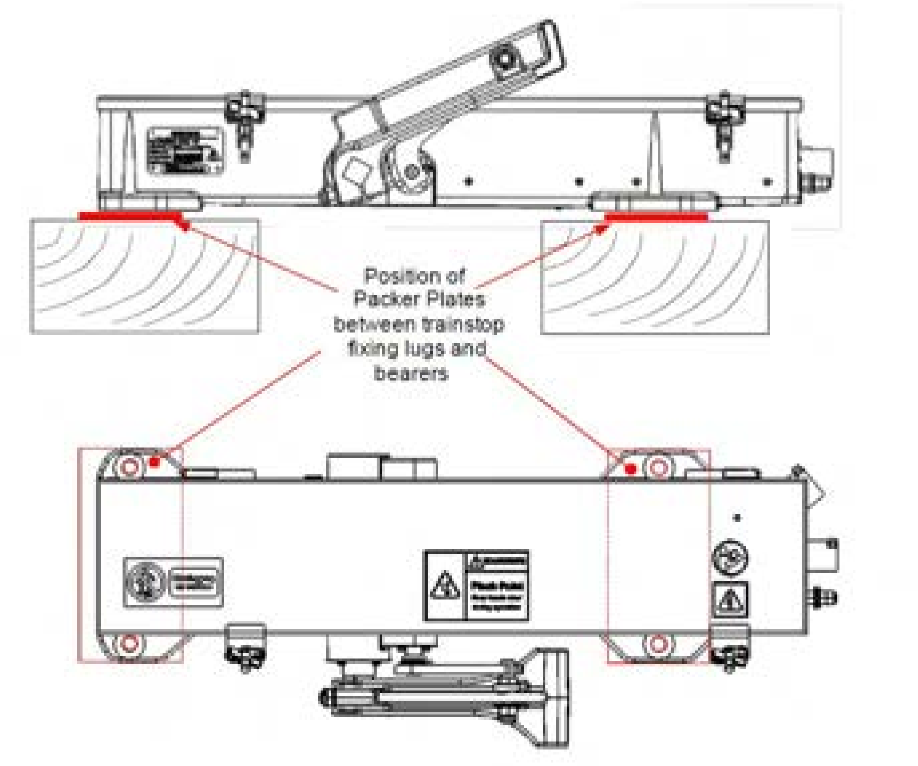

Figure 3 – Position of Packer Plates

If a Sole Plate (B54132/1) is used Packers will be fitted (if required) between the Sole Plate and the Casing Foot.

1.4 If any adjustments have been made carry out SMS Test 027 – JE Style Trainstop Detection Test

End

General

Anti-static precautions shall be taken.

Tools: The following equipment is required to carry out these tests:

- Modulator/Output board extender card. (See Figure 1).
- 1000:1 Current probe.
- Digital voltmeter (DVM).

Figure 1 - Modulator/Output board extender card

1. Loop Test

This test shall only be carried out if a card has been changed

1.1 Take off the cover of the LEU, remove the Modulator/Output board and replace it with an extender card. Plug the Modulator/Output board into the end of the extender card.

1.2 Clip a 1000:1 current probe around the loop cable and connect a DVM to read a current in the range 50-250μA. Verify that both switches on the extender card are in the up position.

1.3 Move switch one to the down position and leave switch two in the up position.

1.4 On the Modulator/Output board adjust the screw in potentiometer L1 to obtain the highest possible meter reading (minimum of 100 μA).

1.5 Leave switch one in the down position and move switch two to the up position.

1.6 On the Modulator/Output board adjust the screw in potentiometer L1 to obtain the highest possible meter reading (minimum of 100 µA).

1.7 Repeat 1.4 & 1.6 until the two reading are as close as possible and still exceed 100 µA.

1.8 Observe that the LED on the Modulator/Output board is illuminated and not flickering. If it is not illuminated or is flickering, repeat the test from 1.3.

1.9 Remove the extender card and replace the Modulator/Output board in the LEU.

1.10 Record the loop current on the ATP record card.

1.11 Remove the current probe and replace the cover.

END

Includes:	AzL Series Axle Counters
Excludes:	All other types of AzLM and AzLE

The system locations details show sites that use the detailed procedure; other unlisted sites may use the same procedure. If you are in ant doubt, ask your SM(S).

1. AzL Series, Procedure 01 - Wembley Control Centre

This axle counter installation has a co-operative reset facility. The circuit makes sure that the technician and the signaller follow the correct resetting procedure.

The reset circuit is fitted with an incremental counter at the evaluator.

Isolate the Axle Counter:

1.1 Contact the signaller and get permission to start. Fill in part A of the axle counter restoration form.

1.2 Write down the restoration counter reading in part A.

1.3 Remove the TPR isolation link. This disconnects the axle counter from the interlocking. Check the ‘INT OCC’ indication is lit (red).

Reset the Axle Counter:

1.4 Contact the signaller and confirm that no trains are in the section. Fill in part 1 of the axle counter restoration form.

1.5 Turn the key-switch to the ‘R’ reset position.

1.6 If the red LED is lit on the GRDFR card in the evaluator counter, you shall reset the card and Check that the LED goes out. If the LED is not lit, proceed to the next step

1.7 Press the ‘Reset’ button. The ‘AC CLEAR’ indication will light up (green).

Restore the Axle Counter:

1.8 Tell the signaller that you are ready to restore the axle counter. Fill in part 2 of the axle counter restoration form. (Stay on the phone and guide the signaller through the final stage).

The signaller is responsible for making sure that the section is clear before the axle counter is restored.

1.9 Turn the key switch back to the ‘N’ position and replace the TPR isolation link.

1.10 Press and hold the ‘Restore’ button. The ‘Restoration available’ indication will start to flash (red).

1.11 Check the signaller has now got a flashing red in the correct axle counter button on his panel. Ask the signaller to pull his button and hold.

1.12 Check the 'Restoration available' indication goes out and the 'Restoration taking place' indication is lit (red).

1.13 Check the signaller's button indication has also gone steady; continue to hold.

1.14 After 10 seconds, the restoration relays will reset.

1.15 The 'Restoration taking place' and 'INT OCC' indications will go out. The 'INT CLEAR' will light up (green).

1.16 The 'Restore' button can now be released.

1.17 Check the restoration counter has increased by one.

1.18 The axle counter has now reset. The indications should be as follows:

Indication	Colour	State
INT Clear	Green	Illuminated
AC Clear	Green	Illuminated
All Others		Extinguished

Fill in part 3 of the restoration form and write down the restoration counter number.

Where possible, watch the first train through the section.

2. AzL Series, Procedure 02 - Crewe Junction Signal Box

This axle counter installation has a co-operative reset facility. The circuit makes sure that the technician and the signaller follow the correct resetting procedure.

The reset circuit is fitted with an incremental counter at the evaluator.

Isolate the Axle Counter

2.1 Contact the signaller and get permission to start.

2.2 Write down the restoration counter reading.

2.3 Remove the TPR isolation link. This disconnects the axle counter from the interlocking. Check the 'AC OCC' indication is lit (red).

Reset the Axle Counter

2.4 Contact the signaller and confirm that no trains are in the section.

2.5 Turn the 'Reset' key-switch to the reset position and hold.

2.6 If the red LED is lit on the GRDFR card in the evaluator counter, you shall reset the card and Check that the LED goes out. If the LED is not lit, proceed to the next step

2.7 Press and release the 'Reset' button. The 'AC CLEAR' indication will light up (green).

Restore the Axle Counter

2.8 Turn the 'Reset' key-switch back to the 'N' position and remove the key. Check that the counter has reset.

2.9 Tell the signaller that you are ready to restore the axle counter. Fill in the axle counter restoration form parts 1 and 2, including the serial number given to you by the signaller. (Stay on the phone and guide the signaller through the final stage).

The signaller is responsible for making sure that the section is clear before the axle counter is restored.

2.10 When the signaller gives you permission, re-connect the TPR isolation link.

2.11 Check the signaller has now got a flashing red in the correct axle counter button on his panel. Ask the signaller to push his button and hold.

2.12 After 10 seconds, the restoration relays will reset and the 'AC CLEAR' will illuminate (green)

2.13 Check the restoration counter has increased by one.

2.14 The axle counter has now reset. Check with the signaller that the track indication is clear and the flashing indicator on the panel has gone out.

2.15 Complete the remainder of the axle counter restoration form and file it in the logbook.

2.16 If the reset is associated with a failure, tell ICC the axle counter reset number and also write it down on your fault report.

2.17 Where possible: Watch the first train through the section.

3. AzL Series, Procedure 03 - Bearley Junction Signal Box

This axle counter installation has a co-operative reset facility. The circuit makes sure that the technician and the signaller follow the correct resetting procedure.

The reset circuit is fitted with an incremental counter at the evaluator.

Isolate the Axle Counter

3.1 Contact the signaller and get permission to start.

3.2 Write down the restoration counter reading.

3.3 Remove the TPR isolation link.

3.4 This disconnects the axle counter from the interlocking. Check the 'AC OCC' and 'INT OCC' indications are illuminated (red).

Reset the Axle Counter

3.5 Contact the signaller and confirm that no trains are in the section.

3.6 Turn the 'Reset' key-switch to the reset position.

3.7 If the red LED is lit on the GRDFR card in the evaluator counter, you shall reset the card and Check that the LED goes out. If the LED is not lit, proceed to the next step

3.8 Press and release the 'Reset' button. The 'AC CLEAR' indication will illuminate (green).

Restore the Axle Counter

3.9 Turn the 'Reset' key-switch back to the 'N' position and remove the key. Check that the counter has reset.

3.10 Tell the signaller that you are ready to restore the axle counter. Fill in the axle counter restoration form parts 1 and 2, including the serial number given to you by the signaller. (Stay on the phone and guide the signaller through the final stage).

The signaller is responsible for making sure that the section is clear before the axle counter is restored.

3.11 When the signaller gives you permission, re-connect the TPR isolation link.

3.12 Press and hold the 'RESTORE' button.

3.13 The 'RESET RELEASE' left hand indication will flash red.

3.14 Check the signaller now has a flashing red in the correct axle counter button on his panel. Ask the signaller to push his button and hold.

3.15 After 10 seconds, the restoration relays will reset.

3.16 The 'RESET RELEASE' will illuminate (red) and the 'INT CLEAR' indication will illuminate (green).

3.17 The 'RESTORE' button can now be released.

3.18 Check the restoration counter has increased by one.

3.19 Check the only indications are as follows:

Indication	Colour	State
INT Clear	Green	Illuminated
AC Clear	Green	Illuminated
All Others		Extinguished

3.20 The axle counter has now reset. Check with the signaller that the track indication is clear and the flashing indicator on the panel has gone out. Complete the remainder of the axle counter restoration form and file it in the logbook.

3.21 If the reset is associated with a failure, tell ICC the axle counter reset number and also write it down on your fault report.

3.22 Where possible: Watch the first train through the section.

4. AzL Series, Procedure 04 - Heath Junction, Caerphilly, Severn Tunnel, and Cwmbran

This axle counter installation has a co-operative reset facility. The circuit makes sure that the technician and the signaller follow the correct resetting procedure.

The reset circuit is fitted with an incremental counter at the evaluator.

Isolate the Axle Counter

4.1 Contact the signaller and get permission to start.

4.2 Remove the TPR isolation link.

4.3 This disconnects the axle counter from the interlocking. Check the ‘Section OC’ indication is illuminated (red).

Reset the Axle Counter

4.4 Contact the signaller and confirm that no trains are in the section.

4.5 Turn the key-switch to the ‘Isolate’ position.

4.6 If the red LED is lit on the GRDFR card in the evaluator counter, you shall reset the card and Check that the LED goes out. If the LED is not illuminated, proceed to the next step

4.7 Press the ‘Reset’ button. The ‘Evaluator clear’ indication will illuminate (green).

Restore the Axle Counter

4.8 Tell the signaller that you are ready to restore the axle counter. The signaller should stamp his train register with the axle counter reset stamp. (Stay on the phone and guide the signaller through the final stage).

The signaller is responsible for making sure that the section is clear before the axle counter is restored.

4.9 Turn the key switch back to the ‘N’ position and replace the TPR isolation link.

4.10 Press and hold the ‘Restore’ button. The ‘Offered’ indication will start to flash (red).

4.11 Check the signaller now has a flashing red in the correct axle counter button on his panel. Ask the signaller to push his button and hold. Check the signaller's indication has gone steady; continue to hold.

4.12 After 10 seconds, the restoration relays will reset.

4.13 The 'Restoration in progress' and 'Section Occupied' indications will extinguish and the 'Section Clear' will illuminate (green).

4.14 The 'Restore button' may now be released.

4.15 Check with the signaller that the restoration counter has increased by one.

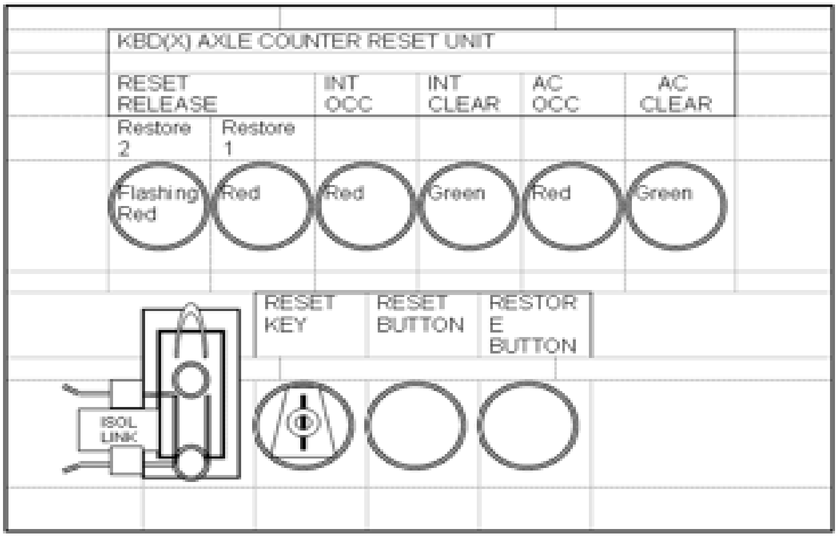
4.16 The axle counter has now reset. The indications should be:

Indication	Colour	State
Section Clear	Green	Illuminated
Evaluator Clear	Green	Illuminated
All Others		Extinguished

4.17 Where possible: Watch the first train through the section.

5. AzL Series, Procedure 05 - Swale

Reset Unit Diagram (not to scale)



Isolate the Axle Counter

5.1 Contact the signaller and get permission to start.

5.2 Write down the restoration counter reading.

5.3 Remove the TPR Isolation Link (this disconnects the axle counter from the interlocking).

5.4 Check the "INT OCC" indicator is lit (red).

Reset the Axle Counter

5.5 Contact the signaller again and confirm that no trains are in the section.

5.6 Complete Part 1 of the axle counter restoration form.

5.7 Turn the key-switch to the reset position. (The 3 0'Clock Position)

5.8 Press the "RESET BUTTON". The "AC CLEAR" indication will light up (green).

5.9 Restore the Axle Counter

5.10 Tell the signaller you are ready to restore the axle counter. Fill in part 2 of the axle counter restoration form. (Stay on the phone and guide the signaller through the final stage).

5.11 The signaller is responsible for making sure that the section is clear before the axle counter is restored.

5.12 When the signaller gives you permission, turn the key-switch back to the normal position (The 6 0'Clock Position) and replace the TPR Isolation Link.

5.13 Press and hold the "RESTORE BUTTON". The signallers axle counter restoration button indication will start to flash (red). The "RESET RELEASE" (Restore 1) steady light is lit (red) in the REB. The restore button SHALL be held in until Step 5.16 below.

5.14 Ask the signaller to press and release his button. The "RESET RELEASE" (Restore 2) indication starts to flash (red) in the REB.

5.15 Ask the signaller to press and release his button again at no less than 10-seconds and no greater than 20-seconds after his initial press in step 5.14 above. (The timing is critical to the restore process). The "INT CLEAR" indication will light up (green). Check the only indications are as follows:

Indication	Colour	State
INT CLEAR	Green	Illuminated
AC CLEAR	Green	Illuminated
All Others		Extinguished

5.16 The axle counter has now reset. The technician can now release the "RESTORE BUTTON". Check with the signaller that the track indication is clear and that the axle restoration counter has incremented by one. Complete part 2 of the axle counter restoration form.

Note: The route will set but the signal(s) will not clear for the first train through the section following an axle counter reset/restoration.

END

Includes:	All Types of Thales Axle Counters
Excludes:	All other types of Axle Counter

GENERAL

Functional tests using the dummy wheel shall require appropriate protection/possession arrangements and liaison with the Signaler.

Specialist Equipment

a) Laptop loaded with the Thales Diagnostic Software (If applicable).

b) Laptop Leads (If applicable).

This test should be carried out when directed (preferred option). In exceptional circumstances it is acceptable, and if a train is available (within 20 minutes), to use the passage of that train.

Refer to NR/SMS/Appendix/15 (General Information on the Thales Axle Counter Systems) for more details on the system.

1. Functional Test with Dummy Wheel (All Types)

This test applies to all affected Detection Points and their associated sections.

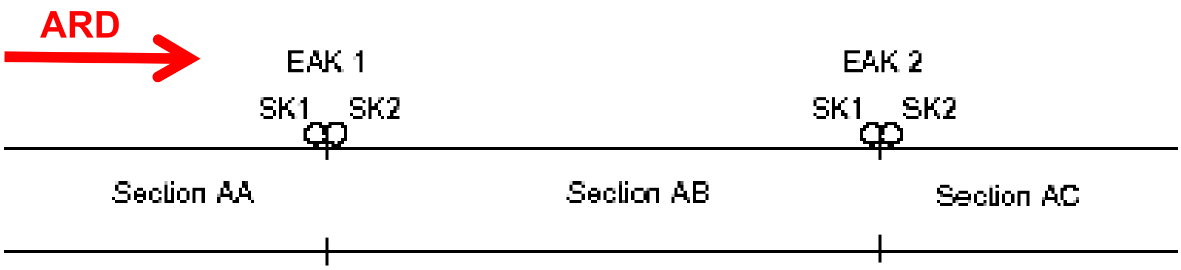


Figure 1 - Typical axle counter section (double rail contacts only)

1.1 Identify the Axle Counter Reference Direction (ARD).

All testing of the sections will be carried in sequence in the reference direction.

1.2 Confirm that the sections to be tested are showing clear.

This should be done using the indications on the ACE / Diagnostic software or by liaising with the Signaller.

1.3 Using the dummy wheel sweep three axles in the direction ARD (in this case of Figure 1 from section AA to section AB).

It should be noted that the sweeping in of the axles will leave section AA in a disturbed state (Shows occupied on the Signaller's panel) and this condition will need to be rectified after the testing is completed

1.4 Check that section AB is showing 'occupied'.

1.5 Confirm with the Signaller and/or indication on ACE or laptop.

1.6 Using the dummy wheel sweep three axles in the opposite direction to the ARD (in this case of Figure 1 from section AB to section AA).

1.7 Check that section AB is showing 'clear'.

1.8 Confirm with the Signaller and/or indication on ACE or laptop.

At boundaries additional factors should be taken into consideration when testing the ARD and other ACE's can be affected.

1.9 On completion of the testing check that all sections are Reset/Clear

END

GENERAL

There are several current variations of Frauscher FAdC in service with Network Rail. Select the Method below that is applicable to your system.

METHOD 1
This method should be used on all Axle counters that are NOT fitted with Counting Head Control (CHC) and/or Supervisor Track Sections (STS) OR those fitted with CHC where the application of EPR's inhibit CHC and/or STS.

METHOD 2
This method should be used on Axle counters that are fitted with Counting Head Control (CHC) where the application of an EPR does NOT inhibit CHC and STS is not configured.

METHOD B - EAST SUFFOLK LINES ONLY
This method is suitable where it is not practicable to observe a train traversing the section to complete the occupancy test.

<u>METHOD 1</u>

1. Before proceeding

1.1 Arrange an EPR with the Signaller.

This task will disturb one or both axle counter sections related to a single wheel sensor and completing this task will cause an error code to occur on one of the axle counter sections associated with the wheel sensor.

This error requires the Signaller's reset procedure to be completed to clear.

2. Sweep Test

2.1 Identify the AEB related to the axle counter sensor to be tested and confirm the section is indicating clear.

2.2 Place the PB200 testing plate on the railhead to the left of the axle counter wheel sensor in the start position (Figure 1).

NOTE: *The AEB card should have two green power LEDs lit. Sys 1 and Sys 2 should not be lit / flashing.*

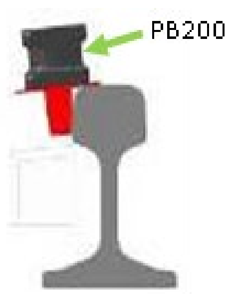

Figure 1 – PB200

2.3 Move (slide) the PB200 slowly in direction of arrow and stop over the first wheel sensor system (Figure 2).

Figure 2 – System 1

Figure 3 – AEB Card

2.4 Check the LED indications SYS1 on the AEB are illuminated (Figure 3).

2.5 Move (slide) the PB200 slowly in direction of the arrow and stop in between the two-wheel sensor systems (Figure 4).

2.6 Check the LED indications SYS1 and SYS2 on the AEB are illuminated (Figure 5).

Figure 4 – Between Systems

Figure 5 – AEB Card

2.7 Move (slide) the PB200 slowly in direction of arrow and stop over the second wheel sensor system (Figure 6).

2.8 Observe the indication SYS1 has extinguished and SYS2 remains illuminated (Figure 7).

Figure 6 – System 2

Figure 7 – AEB Card

2.9 Move (slide) the PB200 slowly away from the sensor to end the simulation. When the PB200 testing plate has passed beyond the sensor check the SYS2 LED has extinguished.

2.10 Check the correct axle counter section has become occupied.

NOTE: *This can be done by either by checking the ASD or by contacting the Signaller. LED A1 or A2 should be permanently lit on the AEB evaluating the section (A1 corresponds to Track Section (FMA1) on AEB and A2 corresponds to Track Section (FMA2)).*

2.11 The PB200 shall now be traversed over the axle counter sensors in the reverse direction to clear the section.

2.12 Confirm the correct axle counter section has cleared.

NOTE: *This can be done by either by checking the ASD or by contacting the Signaller.*

2.13 The Signaller shall now be requested to reset the adjacent axle counter section, if disturbed, and confirm that the section is showing clear.

3. When using the AEB with counting head outputs (e.g. treadle)

3.1 Observe that the system connected to the AEB, COM-XXX shows the following behaviour:

The counting head outputs are output by switching of the counting head outputs from the AEB optocouplers or the IO-EXB relays, or output as an element of the vital protocol of the COM-XXX.

END

METHOD 2

4. Before Proceeding

4.1 Arrange an EPR with the Signaller.

This task will disturb one or both axle counter sections related to a single wheel sensor and completing this task will cause an error code to occur on one of the axle counter sections associated with the wheel sensor.

This error requires the Signaller's reset procedure to be completed to clear.

5. Sweep Test

5.1 Identify the AEB related to the axle counter sensor to be tested and confirm the section is indicating clear.

5.2 Place the PB200 testing plate on the railhead to the left of the axle counter wheel sensor in the start position (Figure 8).

NOTE: *The AEB card should display two green power LEDs lit. LED's A1 and A2 will be flashing ON 50ms OFF 1000ms. AEB is desensitised (CHC active) and FMA Section is clear.*

Figure 8 – PB200

5.3 Move (slide) the PB200 slowly in direction of arrow and stop over the first wheel sensor system (Figure 9).

5.4 Check the LED indications SYS1 on the AEB are illuminated (Figure 10).

Figure 9 – System 1

Figure 10 – AEB Card

5.5 Move (slide) the PB200 slowly in direction of the arrow and stop in between the two wheel sensor systems (Figure 11).

5.6 Check the LED indications SYS1 and SYS2 on the AEB are illuminated (Figure 12).

Figure 11 – Mid Position

Figure 12 – AEB Card

5.7 Move (slide) the PB200 slowly in direction of arrow and stop over the second wheel sensor system (Figure 13).

5.8 Observe the indication SYS1 has extinguished and SYS2 remains illuminated (Figure 14).

Figure 11 – System 2

Figure 12 – AEB Card

5.9 Move (slide) the PB200 slowly away from the sensor to end the simulation. When the PB200 testing plate has passed beyond the sensor check the SYS2 LED has extinguished.

NOTE: *Each sweep must be carried out within 30 seconds to ensure CHC remains inactive.*

5.10 Repeat steps 5.2 to 5.9 to correspond with CHC value, (the CHC value is predetermined by the signalling scheme design of the head under test) LEDS A1 and A2 will stop flashing once the AEB is sensitised (CHC inactive).

5.11 Check the correct axle counter section has become occupied.

NOTE: *This can be done by either by checking the ASD or by contacting the Signaller. LED A1 or A2 should be permanently lit on the AEB evaluating the section (A1 corresponds to Track Section (FMA1) on AEB and A2 corresponds to Track Section (FMA2)).*

5.12 The PB200 shall now be traversed over the axle counter sensor systems in the reverse direction to clear the section.

5.13 Confirm the correct axle counter section has cleared.

NOTE: *This can be done by either by checking the ASD, or by contacting the Signaller.*

5.14 The Signaller shall now be requested to reset any axle counter sections that have been disturbed following the sweep test and confirm that the sections are showing clear.

NOTE: *LED's A1 and A2 will be flashing ON 50ms OFF 1000ms. AEB is desensitised (CHC active) and FMA Section is clear.*

END

METHOD B - EAST SUFFOLK LINES ONLY

This method is suitable where it is not practicable to observe a train traversing the section to complete the occupancy test.

6. Before Proceeding

6.1 Arrange an EPR with the Signaller.

This task will disturb one or both axle counter sections related to a single wheel sensor system and completing this task will cause an error code to occur on one of the axle counter sections associated with the wheel sensor system.

This error requires the Signaller's reset procedure to be completed to clear.

7. Sweep Test

7.1 Identify the adjacent wheel sensor system and AEB related to it and confirm the section is indicating clear.

NOTE: *This is the adjacent section to the one you are testing.*

7.2 Place a PB200 testing plate on the rail head over the centre of the wheel sensor system (Figure 18) and leave in situ to log a permanent occupancy status in the system.

NOTE: *The adjacent section being in a disturbed state supresses the CHC function on the adjacent wheel sensors enabling the occupancy detection capability test to be undertaken.*

7.3 Identify the AEB related to the axle counter sensor to be tested and confirm the section is indicating clear.

7.4 Place the PB200 testing plate on the railhead to the left of the axle counter wheel sensor system in the start position (Figure 15).

Figure 13 – PB200

NOTE: *The AEB card should have two green power LEDs lit. Sys 1 and Sys 2 should not be lit / flashing.*

7.5 Move (slide) the PB200 slowly in direction of arrow and stop over the first wheel sensor system (Figure 16).

7.6 Check the LED indications SYS1 on the AEB are illuminated (Figure 17).

Figure 14 – System 1

Figure 15 – AEB Card

7.7 Move (slide) the PB200 slowly in direction of the arrow and stop in between the two wheel sensor systems (Figure 18).

7.8 Check the LED indications SYS1 and SYS2 on the AEB are illuminated (Figure 19).

Figure 16 – Mid Position

Figure 17 – AEB Card

7.9 Move (slide) the PB200 slowly in direction of arrow and stop over the second wheel sensor system (Figure 20).

7.10 Observe the indication SYS1 has extinguished and SYS2 remains illuminated (Figure 21).

Figure 18 – System 2

Figure 19 – AEB Card

7.11 Move (slide) the PB200 slowly away from the sensor to end the simulation. When the PB200 testing plate has passed beyond the sensor check the SYS2 LED has extinguished.

7.12 Check the correct axle counter section has become occupied.

NOTE: *This can be done by either by checking the ASD or by contacting the Signaller. LED A1 or A2 should be permanently lit on the AEB evaluating the section (A1 corresponds to Track Section (FMA1) on AEB and A2 corresponds to Track Section (FMA2)).*

7.13 The PB200 shall now be traversed over the axle counter sensor systems in the reverse direction to clear the section.

7.14 Confirm the correct axle counter section has cleared.

NOTE: *This can be done by either by checking the ASD or by contacting the Signaller.*

7.15 The Signaller shall now be requested to reset the adjacent axle counter section, if disturbed, and confirm that the section is showing clear.

END

Includes:	ACM 100 (ACM module and WSD wheel detector)
Excludes:	AzS 350 U, AZM, ZP D 43 and ZP 43 V, WSR and WSS

This test requires a Fluke 771 Milliamp Process Clamp Meter. Other clamp meters shall not be used during this test as these can give inaccurate measurements. The clamp meter shall be reset to zero before use.

Keep switched on mobile phones 3m away from the counting heads whilst undertaking maintenance as they can cause false-counts/readings.

Keep metallic objects at least 20cm away from the counting heads. The movement of metallic objects including tools, steel toe-cap boots and jewellery across the upper surface of the counting heads may cause occupation of the track sections.

Do not step directly across the top of the wheel sensor during the calibration process.

If during installation the temperature of the wheel detector differs by more than 10°C from the temperature of the rail, it shall be allowed to equalise before calibration is performed. This could potentially be an issue when moving a WSD from Vehicle to Rail.

All wires of the connecting cable to the wheel detector can be subject to interference voltages. Do not touch live parts. This is particularly to be observed when working on the junction box (attaching wires, performing checks).

1. Calibration of the Wheel Sensor

1.1 Make suitable arrangements with the signaller for possession of the relevant axle counter sections.

One wheel detector can affect more than one section.

1.2 Connect the clamp meter around wire 1 of the wheel detector.

A current of approximately 5mA should be expected if the wheel sensor has been working in service. Other currents might be seen with uncalibrated wheel sensors.

1.3 Disconnect wire 1 of the wheel detector.
This can usually be achieved by opening a link in the trackside disconnection box.

Steps 1.4 to 1.6 are timed steps.

1.4 After at least 5 seconds of wire 1 being disconnected, reconnect wire 1 then wait approximately 30 seconds (minimum 15 seconds, maximum 45 seconds) and check that the current measured is now between 1.3mA and 7mA. If the reading is outside of this range, check the sensor is fitted correctly to the rail and no metallic objects are interfering with the measurement then return to step 1.1.

1.5 Place the adjustment gauge (1) on the top of the wheel detector as shown in figure 1.

a) The green metal strip **(2)** should be on the bottom of the adjustment gauge against the WSD.

b) The adjustment gauge should rest against the rail head.

c) The "Cal." **(3)** marking should coincide with the centre marking **(4)** on the wheel detector housing.

Do not move the position of the adjustment gauge after it has been placed on the sensor.

Check the clamp meter indicates a current consumption between 1.2 mA and 2.99 mA.

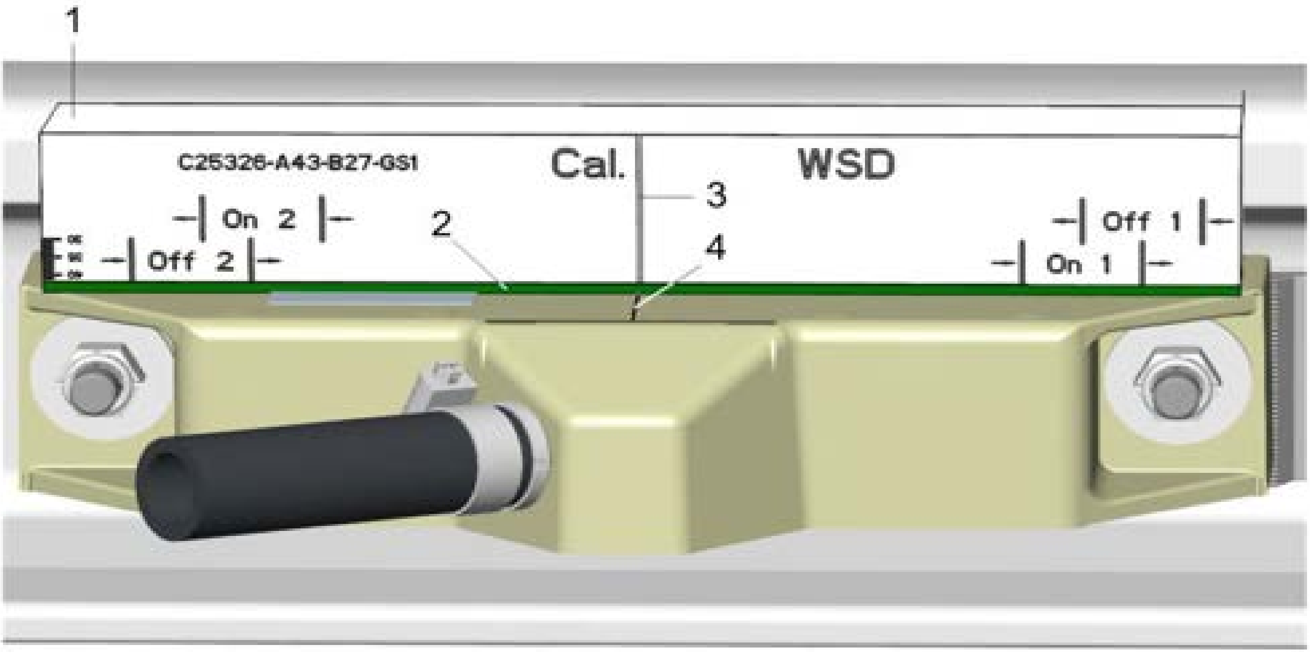

Figure 1 – Positioning of the adjustment gauge on the wheel detector

1.6 Leave the adjustment gauge on the wheel detector for approximately 30 seconds (minimum 15 seconds, maximum 40 seconds) before completely removing it from the wheel detector.

Approximately 25 seconds after removing the block the wheel detector adopts the calibrated value. Check the current reading now reads between 4.75 mA and 5.25 mA.

The calibration of subsystem 1 is now complete.

1.7 Move the clamp meter from wire 1 to wire 4

1.8 Disconnect wire 4 of the wheel detector.
This can normally be achieved by opening a link in the trackside disconnection box.

Steps 1.9 to 1.11 are timed steps

1.9 After at least 5 seconds of wire 4 being disconnected reconnect wire 4, wait approximately 30 seconds (minimum 15 seconds, maximum 45 seconds). Check that the current measured during this period is between 1.3mA and 7mA. If the reading is outside of this range check the sensor is fitted correctly to the rail and no metallic objects are interfering with the measurement then return to step 1.8.

1.10 Place the adjustment gauge (1) on the top of the wheel detector as shown in figure 1.

a) The green metal strip **(2)** should be on the bottom of the adjustment gauge.
b) The adjustment gauge should rest against the rail head.
c) The "Cal." **(3)** marking should coincide with the center marking **(4)** on the wheel detector housing.

Do not move the position of the adjustment gauge after it has been placed on the wheel sensor.

Check the clamp meter indicates a current consumption of the wheel detector between 1.2 mA and 2.99 mA.

1.11 Leave the adjustment gauge on the wheel detector for approximately 30 seconds (minimum 15 seconds, maximum 40 seconds) before completely removing it from the wheel detector.

Approximately 25 seconds after removing the block the wheel detector adopts the calibrated value. Check the current reading now reads between 4.75 mA and 5.25 mA.

1.12 Remove the clamp meter from wire 4.

The calibration of subsystem 2 is now complete.

1.13 Perform a functional test of the wheel sensor [NR/SMS/Test/039] before returning to service.

End

Includes:	ACM 100 (ACM module and WSD wheel detector)
Excludes:	AzS 350 U, AZM, ZP D 43, ZP 43 V, WSR and WSS

This test requires a Fluke 771 Milliamp Process Clamp Meter, Other clamp meters shall not be used during this test as these can give inaccurate measurements. The clamp meter shall be reset to zero before use.

Keep switched on mobile phones 3m away from the counting heads whilst undertaking maintenance as they can cause false-counts/readings.

Keep metallic objects at least 20cm away from the counting heads. The movement of metallic objects including tools, steel toe-cap boots and jewellery across the upper surface of the counting heads may cause occupation of the track sections.

Do not step directly across the top of the wheel sensor during the calibration process.

All wires of the connecting cable to the wheel detector can be subject to interference voltages. Do not touch live parts. This is particularly to be observed when working on the junction box (attaching wires, performing checks).

Test of the Wheel Sensor

This procedure describes the functional test of the WSD wheel detector. It shall be used immediately after a calibration has been carried out to prove the calibration was successful. It can also be used at other times to assess the performance of the wheel sensor.

Do not disconnect any wires or remove any links before or during functional testing.

1.1 Make suitable arrangements with the signaller for possession of the relevant axle counter sections.

One wheel detector can affect more than one section.

1.2 Connect the clamp meter to wire 1 of the wheel detector. The current clamp reading should indicate a current between 4.75 mA and 5.25 mA.

If a negative value is indicated, this is because of the physical orientation of the clamp meter on the wire and does not affect the accuracy of the measurement. If this occurs, readings can continue to be made and the negative sign ignored.

1.3 Place the adjustment gauge on the top (see figure 1) of the wheel detector as follows:

a) The adjustment gauge **(1)** should rest against the rail head.

b) The green sheet-metal strip **(2)** should be located on the side facing away from the rail head.

The clamp meter should now indicate a value between 1.3 mA and 2.99 mA. Record the value on the Wheel Detector Record Card.

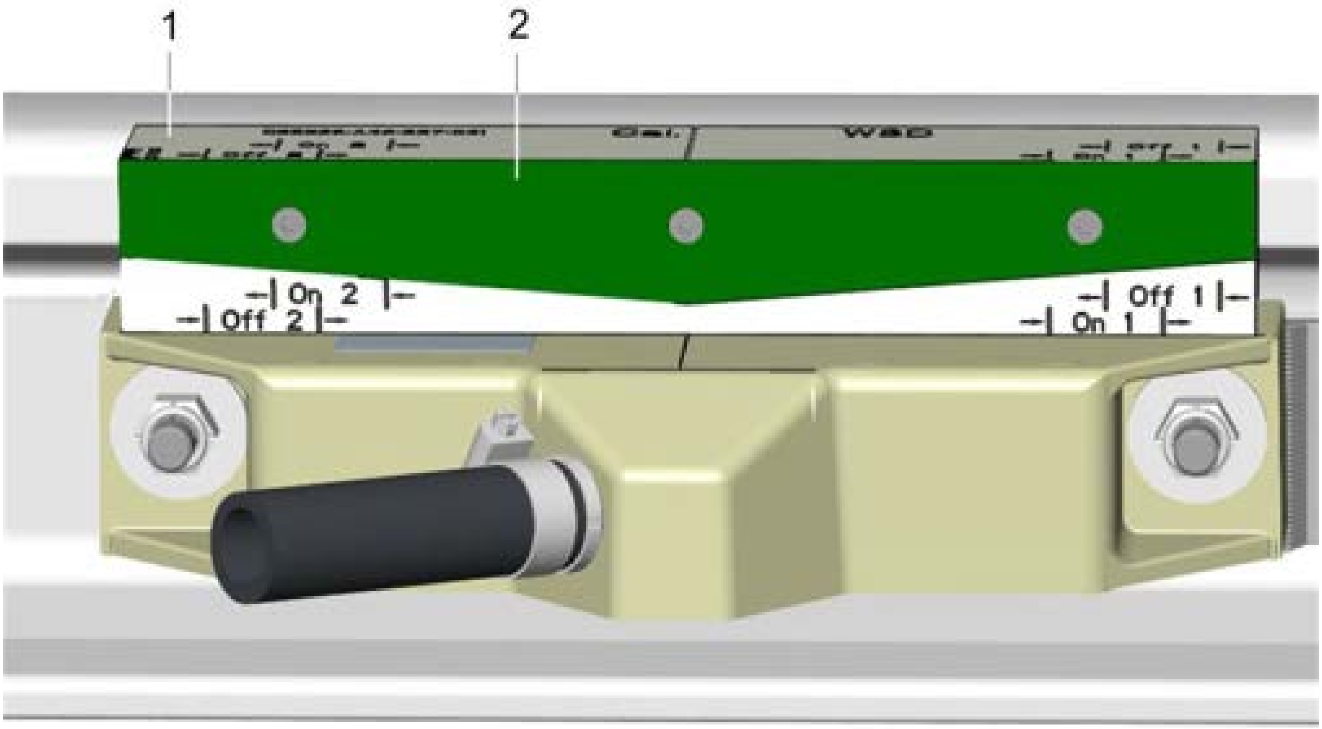

Figure 1 – Positioning of the adjustment gauge on the wheel detector

1.4 Move the adjustment gauge along the rail over the wheel detector in direction A (see figure 2). The adjustment gauge should be in contact with the wheel detector and rail when doing so.

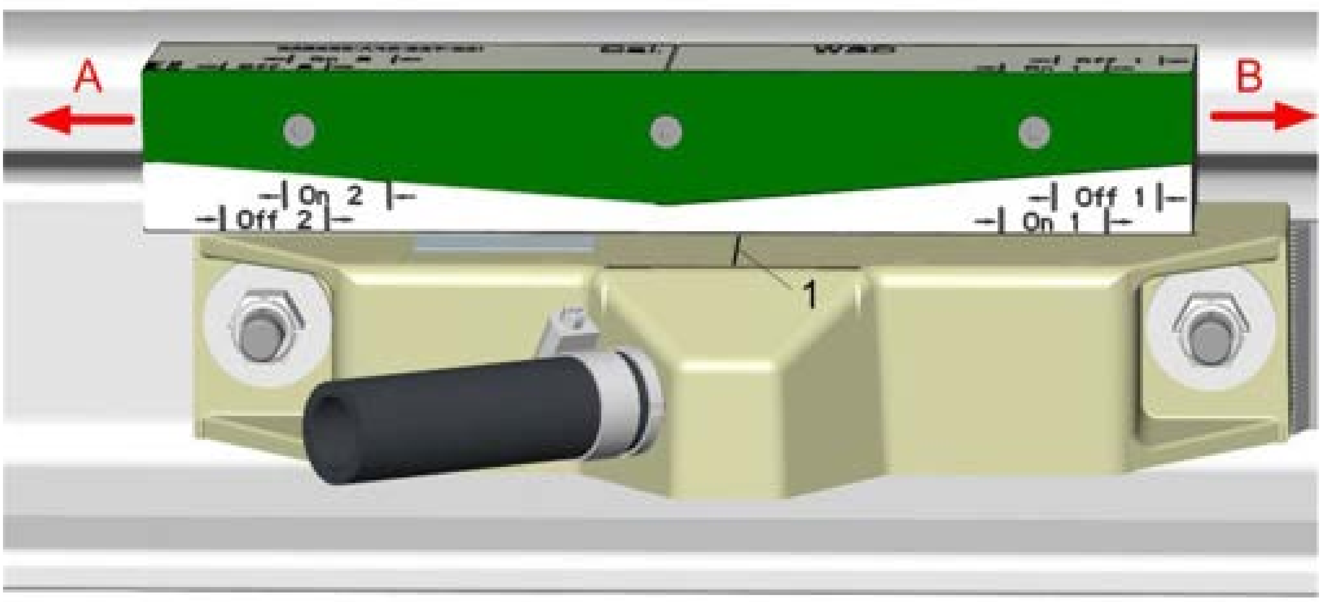

Figure 2 – Movement of the adjustment gauge towards A

1.5 Continue to move the adjustment gauge in direction A (see figure 3) until the measured current rises to a value between 4.75 mA and 5.25 mA. Then check whether the centre marking (1) on the wheel detector is between the "Off 1" markings on the adjustment gauge. A tolerance of 10 mm on both sides of the "Off 1" markings is permissible (see figure 3). Record the result of the test on the Wheel Detector Record Card.

> Do not leave the adjustment gauge in position continue and complete functional testing with step more than 1.6 within 40 seconds

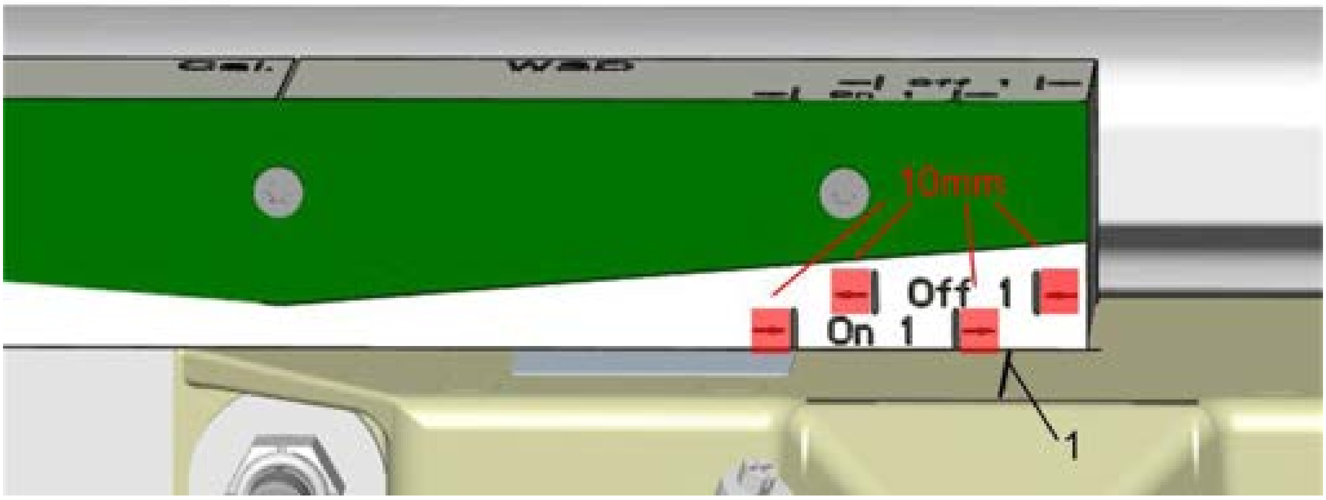

Figure 3 – Continued movement of the adjustment gauge towards A

1.6 Move the adjustment gauge back in direction B until the measured current has dropped again to a value between 1.3 mA and 2.99 mA. Then check whether the center marking (1) on the wheel detector is between the "On 1" markings on the adjustment gauge. A tolerance of 10 mm on both sides of the "On 1" markings is permissible.

Record the result of the test on the Wheel Detector Record Card

1.7 Return the adjustment gauge to its initial position (see figure 1 and Step 1.3).

1.8 Remove the clamp meter from wire 1.

1.9 Connect the clamp meter to wire 4. The clamp meter shall indicate a value between 1.3 mA and 2.99 mA.

Record the value on the Wheel Detector Record Card.

1.10 Move the adjustment gauge along the rail over the wheel detector in direction B. The adjustment gauge should be in contact with the wheel detector and rail when doing so

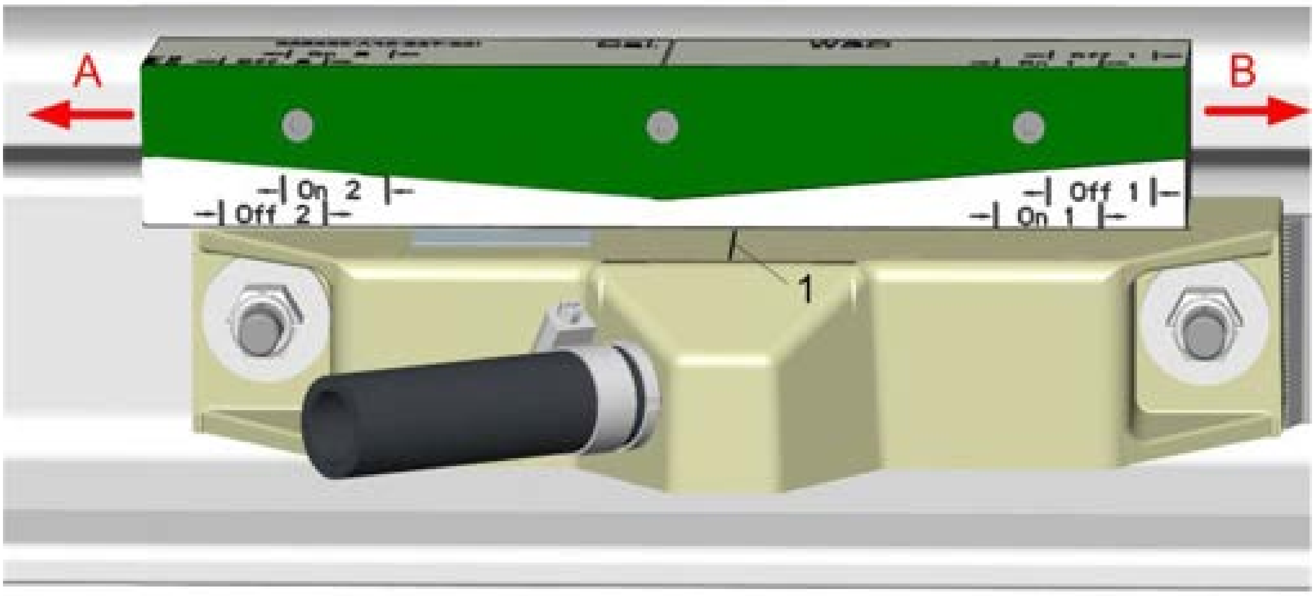

Figure 4 – Movment back towards A

Continue moving the adjustment gauge in direction B until the measured current rises to a value between 4.75 mA and 5.25 mA. Then check whether the center marking (1) on the wheel detector is between the "Off 2" markings on the adjustment gauge. A tolerance of 10 mm on both sides of the "Off 2" markings is permissible. Record the result of the test on the Wheel Detector Record Card.

Do not leave the adjustment gauge in position continue and complete functional testing with step more than 1.11 within 40 seconds

1.11 Move the adjustment gauge back in direction A (see figure 4)until the measured current has dropped to a value between 1.3 mA and 2.99 mA. Then check whether the center marking (1) on the wheel detector is between the "On 2" markings on the adjustment gauge. A tolerance of 10 mm on both sides of the "On 2" markings is permissible.

Record the result of the test on the Wheel Detector Record Card

1.12 Remove the adjustment gauge from the wheel detector and clamp meter from wire 4.

1.13 The wheel detector will function correctly if the gauge has been within the permitted range during tests for “On” and “Off” on both System 1 and System 2. If the gauge is outside the permitted range the wheel detector requires recalibration. If unsuccessful after recalibration replace the wheel detector as corrective maintenance.

1.14 Simulate two train wheels passing over the sensor. To pass a simulated wheel, start with the test block in position (1) shown in the diagram below, pass through position (2) to position (3) before removing the test block. Note that the test block must be orientated as shown in figure 5, with the green metal plate on the side away from the rail head.

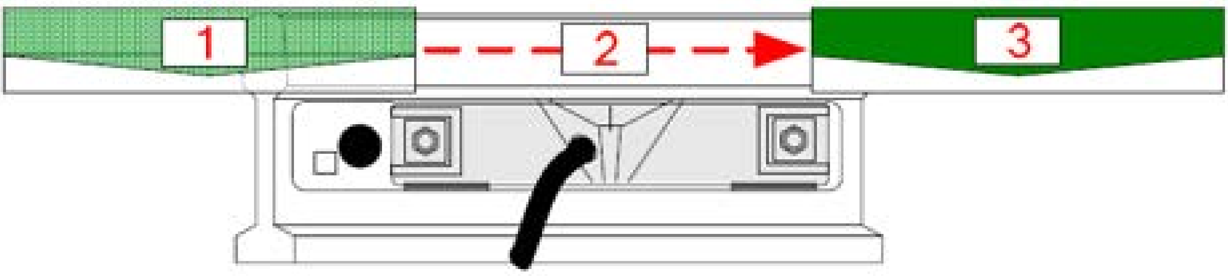

Figure 5 – Simulate Train

1.15 Check that the WSD LEDs on the ACM100 module for the affected sensor are showing solid green. If they are flashing green, repeat step 1.14. Only once the WSD LEDs are solid green, the signaller can be informed that work is complete and the section may be reset.

End

Includes:	RSR 123 Wheel sensors associated with Frauscher Advanced Evaluation Boards (AEB)
Excludes:	RSR123 Wheel sensors associated with IMC Boards

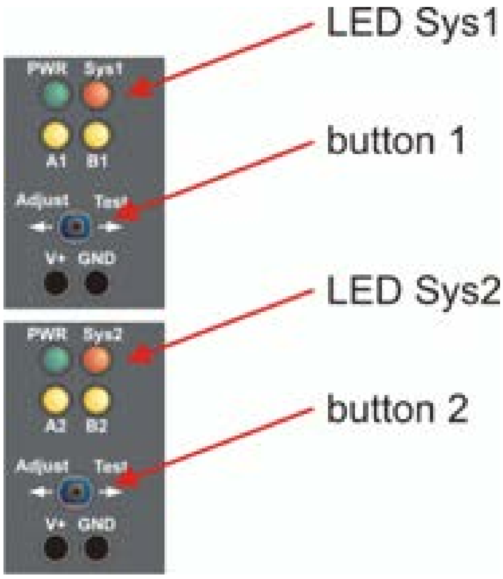
General

Before adjustment, check that wheel sensor RSR123 attached to the AEB is correctly mounted.

During adjustment, check that the wheel sensor RSR123 attached to the AEB is not occupied.

1. The button actuation sequence:

1.1 Push both buttons to the left (direction “Adjust”) within half a second.



1.2 Retain both buttons in this position for at least half a second.

1.3 Release both buttons within half a second.

1.4 Retain both buttons in the normal position for a maximum of 2 seconds.

1.5 Push both buttons to the right (direction “Test”) within half a second.

1.6 Retain both buttons in this position for at least half a second.

1.7 Release both buttons within half a second.

After the correct initiation of the adjustment sequence, Sys1 and Sys2 LEDs illuminate for between 20 to 80 seconds. Once adjustment has been carried out successfully, Sys1 and Sys2 LEDs go out.

If the adjustment is unsuccessful, the Sys1 and Sys2 LEDs flash rapidly (10 times per second), for 2 seconds.

To start a new adjustment, recommence the actuation sequence (points 1 to 7) from the start. The actuation sequence should prevent accidental actuation of one or both buttons starting an adjustment process.

1.8 The Signaller should now be requested to reset the axle counter section.

1.9 Carry out NR/SMS/PartB/Test/037 (Frauscher: RSR123 Wheel Sensor Occupancy Detection Capability Test).

END

GENERAL

The purpose of this test is to determine whether any fishplates or bolts of an insulated joint are in electrical contact with either rail.

When a track repair or insulated IBJ is changed a full test shall be carried out. Record details on the Record Card.

<u>**Select one of the following Tests:**</u>

1. IRJ Tester

1.1 Test insulated rail joints using IRJ tester.

Follow the user instructions provided with the equipment. Only use testers on authorised TC types.

1.2 List each rail joint that results in a red or yellow reading and forward the results to your SM(S).

2. 220Ω Shunt Resistance Test

This test can be carried out on all DC track circuits and the WR Quick Release Track Circuit (for which AC voltage should be measured).

2.1 For double rail track circuits, strap out the opposite IRJ.

2.2 Connect a 220Ω (+/- 10%) shunt across the meter.

2.3 Measure and record voltages V1, V2 & V3. The results and outcomes are as follows:

a) If V2 and V3 are less than or equal to 10% of V1, the IRJ is satisfactory.

b) If V2 or V3 are between 11% and 50% of V1 then the IRJ is degrading and shall be monitored.

c) If V2 or V3 are greater than 50% of V1 then the IRJ has failed and shall be reported as requiring replacement.

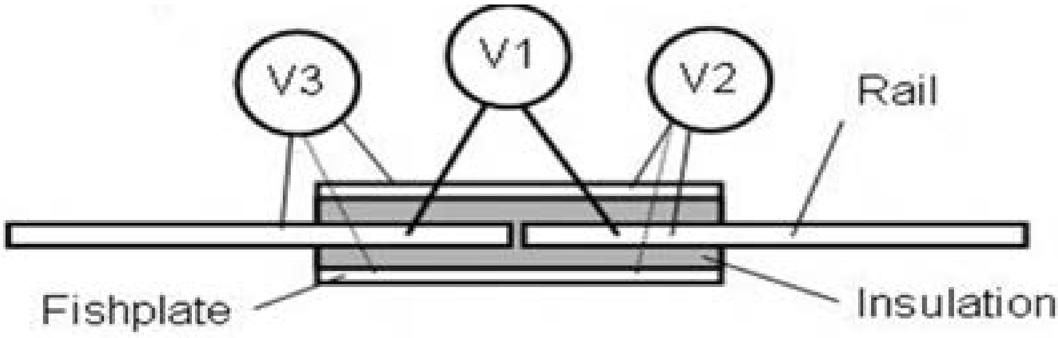


Figure 1 – Measurements V2 and V3 apply to both the inner and outer plates of the IRJ

3. Current Probe Test

3.1 Secure the probe connected to a digital meter around the rail adjacent to the IRJ and between the IRJ and any track connection.

3.2 Check the current value is less than 5mA.

3.3 If any readings are greater than 5mA or any other defects are noted, the joint is faulty and shall be reported. It is essential for the continued correct operation of the track circuit that the joint is repaired or replaced as soon as reasonably practicable.

4. Resistance checks

4.1 HVI tracks only: Power down prior to testing to prevent possible damage to meter.

4.2 Check test prods are sharp to improve electrical contact.

4.3 Remove any rail end burrs and visually inspect end post.

4.4 Remove any swarf or metallic debris.

4.5 Where possible use a shiny part of the wheel-rail contact area as a test point.

4.6 Where another surface is to be used, scrape contact surface and loop test with both prods to confirm good electrical contact before resistance testing is carried out.

4.7 Check that the resistance between each rail and the inner fishplate is at least 150ohms.

4.8 Check that the resistance between each fishplate bolt and the rail it bolts through is at least 150ohms.

4.9 Check that the resistance between each rail and the outer fishplate is at least 150ohms.

5. AC Track Circuits

This test is for use with IRJ's on 50Hz AC track circuits only.

Operational track circuits on the other side of the insulated rail joint can be AC, TI21, FS2600 or Reed type. HVI tracks should be powered down prior to testing to prevent possible damage to meter.

The test does not apply to insulated rail joints such as the Treble 6 or Permali that use split fishplates.

Use an AVO8 or similar low impedance moving coil type meter set to Ohms range. Electronic meters do not give good open circuit readings.

Test prods should be sharp to improve electrical contact.

5.1 Remove any rail end burrs and visually inspect end post. Remove any swarf or metallic debris.

5.2 Where possible use a shiny part of the wheel-rail contact area as a test point.

Where another surface is to be used, scrape contact surface and loop test with both prods to confirm good electrical contact before resistance testing is carried out.

5.3 Check that the resistance between each rail and the inner fishplate is at least 150Ω.

5.4 Check that the resistance between each inner fishplate bolt and the rail it bolts through is at least 150Ω.

5.5 Check that the resistance between each rail and the outer fishplate is at least 150Ω.

5.6 Check that the resistance between each outer fishplate bolt and the rail it bolts through is at least 150Ω.

5.7 If any readings are below 150Ω or any other defects are noted that part of the joint is faulty and shall be reported as a corrective maintenance item. It is essential for the continued correct operation of the track circuit that the joint is repaired or replaced as soon as reasonably practicable.

APPENDIX A - Photographic Examples of Insulated Block Joints

Figure 2 shows an IBJ in good condition (no lipping or contamination).

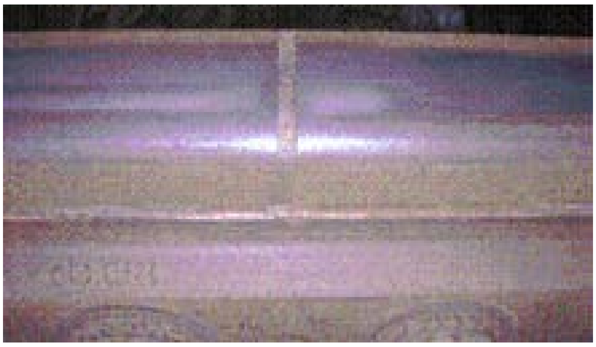

Figure 2 - Good Condition

Figure 3 shows how the wrong clips used can short circuit around the insulation.

Figure 3 – Wrong Clips

Figure 4 illustrates that the IBJ could not be installed correctly because the sleeper spacing is incorrect which places the baseplates in the wrong position and makes it impossible to fit one pair of Clips and Insulators.

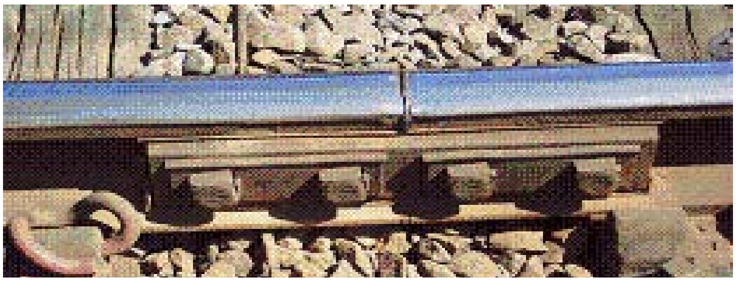

Figure 4 – Incorrect sleeper spacing

Figure 5 shows a lipped joint which causes a track circuit to fail and should be rectified when found

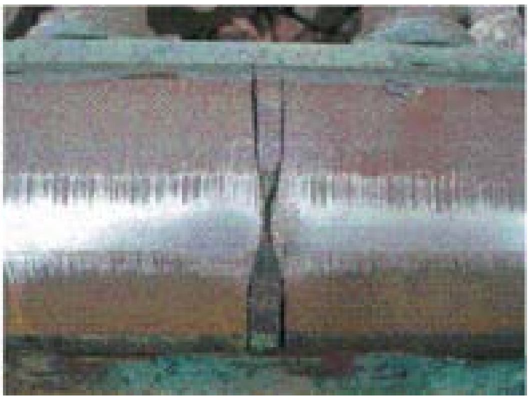

Figure 5 – Lipped Joint

Figure 6 shows a block joint suffering from metallic contamination which causes a track circuit and be rectified when found.

Figure 6 – Metallic Contamination

Figure 7 shows a joint with the end post missing. Often the bottom section of the end post can be found lying beneath the joint where it has been forced out. This causes a track circuit failure and needs rectifying as soon as possible

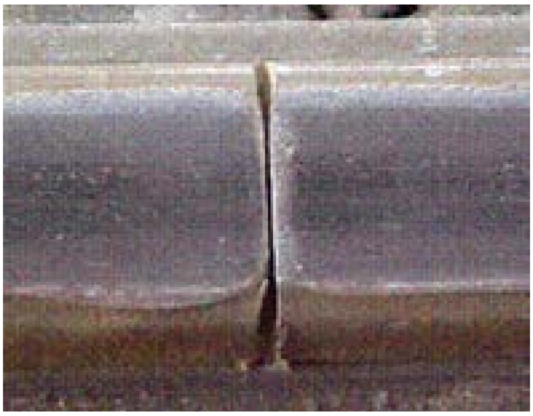

Figure 7 – End Post Missing

END

Includes:	AzL70 Single Rail Contacts with EAK Junction Box, AzL70 and AzL70/30 & AzL70/30S Double Rail Contacts with EAK30 Junction Box
Excludes:	All other types of AzLM and AzLE

Functional tests using the dummy wheel require protection/possession arrangements and liaison with the Signaller first.

These tests are required when the rail contacts are moved or re-aligned. They also usually form part of the annual test of axle counters.

Refer to NR/SMS/Appendix/15 for additional system details.

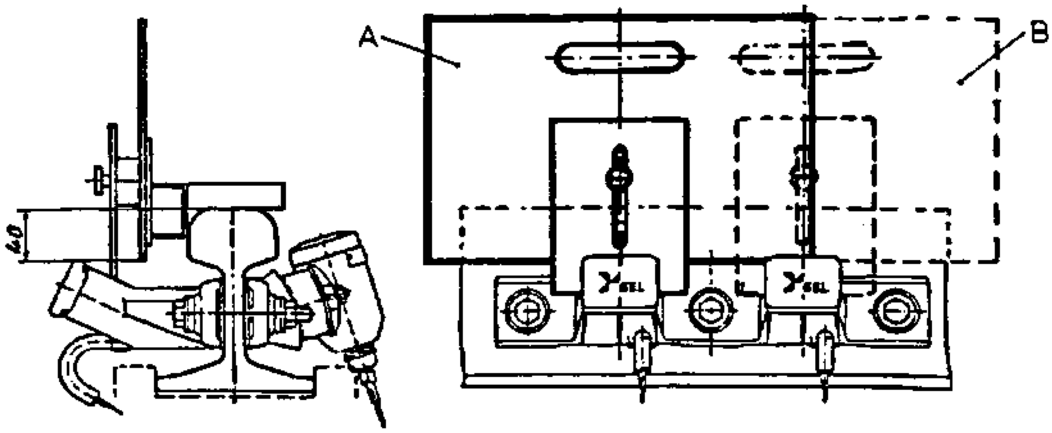

Figure 1 - Position of Dummy Wheel during Testing

Right hand diagram shows a side on view and the left shows the dummy wheel place over rail contact SK1(marked A) and over SK2 (marked B).

To simulate a wheel on an axle counter a dummy wheel supplied by the manufacturer is used. It consists of a metal plate with three plastic brackets.

The bottom edge of the plate is to be adjusted to 30mm for single rail contacts and 40mm for all double rail contacts.

The two brackets are swung out 90° to the metal plate and rest on the top rail.

The third bracket is flat and parallel to the metal plate. It holds the metal plate in the correct position by resting on one of the Rx coils to influence a count head or in double rail contacts across both Rx coils to influence both heads simultaneously.

If it is required to simulate several wheels passing over the rail contacts, loosen the knurled nut and raise the flat bracket so that it is clear of the Rx coils while the device is passing over the heads.

The cut out notch on the third bracket should be aligned with the center mark on the received head when readings are being taken.

All measurements shall be recorded on the record card.

<u>AzL70 Single Rail Contacts with EAK Junction Box (Only)</u>

1. Phase Reversal Test

1.1 Check that the cable cores on the power cable are twisted together. Also check that each Tx and Rx cable have their respective cores twisted together to the point 25mm of termination point.

1.2 Connect a meter to the terminations within the lineside amplifier with the +ve lead to AL4/3 and the –ve lead to AL4/4. Check the voltage is between 400mV to 600mV.

1.3 Insert the dummy wheel (adjusted to a depth of 30mm) over SK1 rail contact on the 6ft rail and check the reading is less than 50mV.

If this voltage reading is not achieved the count head will require adjusting up or down to obtain this.

1.4 Remove the dummy wheel from over SK1 count head and observe that the voltage reading returns to its original value.

1.5 Change the meter connections to the +ve lead to AL4/1 and the –ve lead to AL4/2 and repeat 1.1 to 1.3 with the dummy wheel over SK2 rail contact on the cess rail.

2. Adjustment of Count Heads

2.1 Note which step the relevant TX head is on, slacken the head adjusting bolts and move the head up or down one step.

2.2 Tighten the head adjusting bolts and repeat 1.1 and 1.2.

2.3 Compare the readings between 1.1 and 1.2, if the voltage is now less than 50mV go to 2.4. If the voltage is still outside this limit repeat 2.1

If after adjustments of the count head it is not possible to obtain a voltage of less than 50mV, obtain the lowest difference possible and inform your SM(S).

2.4 Check that after adjusting the rail contacts all adjusting nuts are tightened.

AzL70, AzL70/30, AzL70/30S Double Rail Contacts with EAK30 Junction Box (Only)

3. Phase Reversal Test

3.1 Check that the cable cores on the power cable are twisted together. Also check that each Tx and Rx cable have their respective cores twisted together to the point 25mm of termination point.

3.2 Connect either the Thales Test Unit (silver suitcase) or the BR designed lineside test switch box connected to a meter to the LtAnp card in the EAK30 junction box.

3.3 Select position 10 (MESSAB 1) on the switch box and check the reading is between +55mV to +1000mV.

3.4 Insert the dummy wheel (adjusted to a depth of 40mm) between SK1 TX/RX count head and check the reading is between -55mV to -1000mV.

3.5 Compare the readings between 3.2 and 3.3, if they are within 25mV of each other (with opposite polarities) proceed to 3.5. If the voltage is outside this limit go to section 4.

3.6 Select position 12 (MESSAB 2) and repeat sections 3.2 and 3.3 for the SK2 count head.

3.7 Compare the readings between 3.2 and 3.3, if they are within 25mV of each other (with opposite polarities) proceed to section 5 if the voltage is outside this limit go to section 4.

4. Adjustment of Count Heads

4.1 Note which step the relevant TX head is on, slacken the head adjusting bolts and move the head up one step if the positive reading was higher than the negative one, conversely move the head down one step if the positive reading was lower than the negative one.

4.2 Tighten the head adjusting bolts and repeat 3.2 and 3.3 remembering to select MESSAB 1 for head SK1 and MESSAB 2 for head SK2.

4.3 Compare the readings between 3.2 and 3.3, if they are now within 25mV of each other proceed to section 5. If the voltage is still outside this limit repeat 4.1.

If after adjustments of the count head it is not possible to obtain a voltage of less than 50mV, obtain the lowest difference possible and inform your SM(S).

4.4 Check that after adjusting the rail contacts all adjusting nuts are tightened.

5. Adjustment of PEGUE

5.1 Remove the dummy wheel from the count heads and select position 10 (MESSAB 1) on the test box and measure the reading.

5.2 Select position 11 (PEGUE 1) on the test box and if necessary, by means of the potentiometer on the SE01 card adjust the voltage until the PEGUE 1 reading is the same as the MESSAB 1 reading.

5.3 Repeat 5.1 using position 12 (MESSAB 2).

5.4 Repeat 5.2 using position 13 (PEGUE 2) and if necessary, adjusting the potentiometer on the SE02 card.

6. Output Voltage Checks

6.1 Observe that both green LEDs on the SE01 and 02 cards are lit (flashing on 70/30S), connect the meter to the LTG1 terminals on the lineside test box and select the AC voltage range.

6.2 Insert the dummy wheel at the SK1 head, observe the LED's on card SE01 shows red and SE02 is extinguished. Measure the output voltage and frequency and check the readings are as follows:

a) 400mV to 550mV AC @ 4.15 kHz ±2% (70/30).

b) 400mV to 550mV AC @ 2.04kHz ±2% (70/30S).

6.3 Move the dummy wheel to the SK2 head and observe the LED's now show SE01 extinguished and SE02 red. Measure the output voltage and frequency and check the readings are as follows:

a) 400mV to 550mV AC @ 5.06 kHz ±2% (70/30).

b) 400mV to 550mV AC @ 2.52kHz ±2% (70/30S).

6.4 Remove the dummy wheel and measure the output voltage, check the readings are as follows:

a) 700mV to 1100mV AC (70/30).

b) 600mV to 900mV AC (70/30S).

6.5 Place the dummy wheel over both count heads, observe that both red LED's are lit and the green LED's are extinguished. Measure the voltage at the LTG1 terminals on the test box and check it is less than 100mV AC.

If the voltage is greater than this, switch off the battery charger feeding the EAK and test again. If the voltage is still greater, the cause shall be investigated as corrective maintenance.

6.6 Remove the dummy wheel and observe that both the red LEDs are extinguished and both the green LEDs are lit (flashing on type 70/30S).

END

GENERAL

This test requires the use of the TCAID tester.

1. Preparations for Testing

1.1 Isolate track circuit supply.

1.2 Open the dis-box and, in turn, move each of the sliding links and secure in the open circuit position.

1.3 Fit the four coloured test leads into the TCAID tester matching coloured sockets.

2. Connecting the TCAID Tester

2.1 Connect the tester as shown below (Fig 1- non directional MOD 0-2 versions, Fig 2- non directional MOD 3 versions, Fig 3 – directional), checking that any un-terminated leads are isolated from each other and terminals / metalwork.

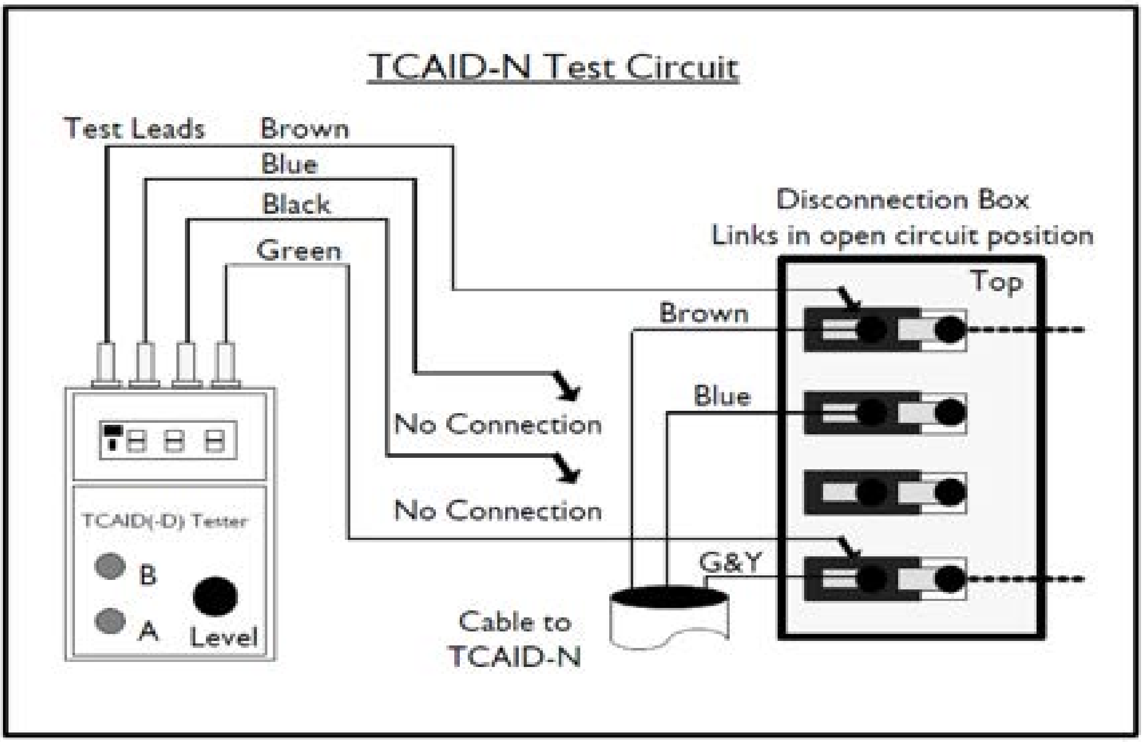

Figure 1 - Tester set up (non-directional) for MOD 0-2 versions

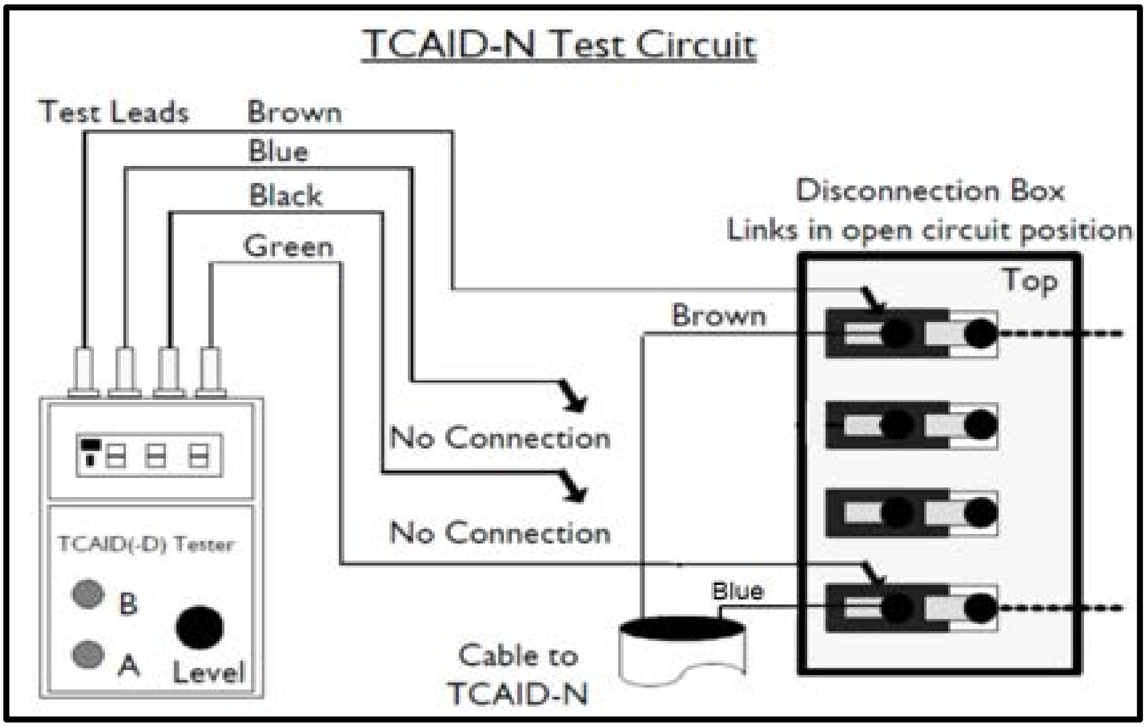

Figure 2 - Tester set up (non-directional) for MOD 3 versions

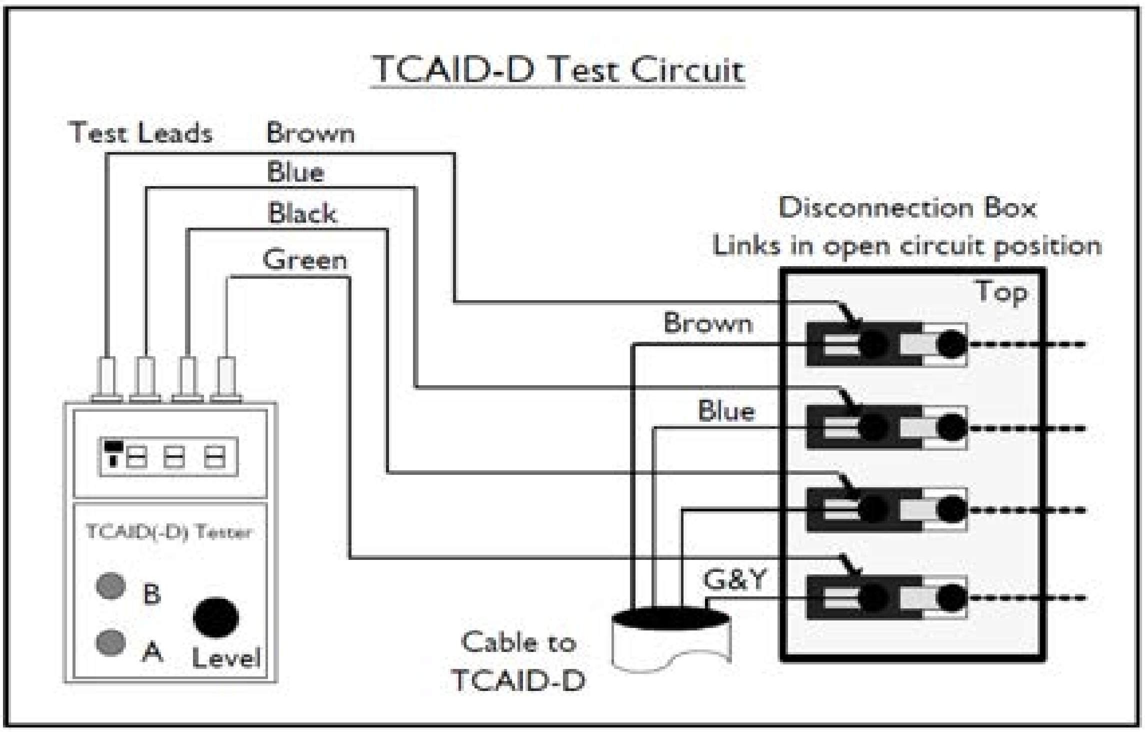

Figure 3 - Tester set up (directional) for all MOD versions

3. Test Procedure for all types of TCAID

A TCAID is only considered healthy if it passes all the tests described for it.

3.1 Using the TCAID tester rotate the level control fully anti-clockwise and press and hold down the PHASE A button - the display can become active.

The button shall be held down for the duration of the first part of the test. If the display goes blank, the test shall be re-started from step 3.1.

3.2 Slowly rotate the level control clockwise until the TCAID OPERATED symbol appears on the display. Note the reading on the display and check it is within the values shown in Table 1:

TCAID Type	Mk1	Mk2
TCAID-N Activates	325mV to 360mV	315mV to 385mV
TCAID-D Activates	405mV to 460mV	315mV to 385mV

Table 1 - Test Limits Activation

Readings outside these limits indicate a failed TCAID.

3.3 Slowly rotate the level control back (anti-clockwise) until the TCAID OPERATED symbol disappears. Note the reading on the display and check it is within the values shown in Table 2:

TCAID Type	Mk1	Mk2
TCAID-N De-Activates	335mV to 265mV	190mV to 270mV
TCAID-D De-Activates	300mV to 330mV	190mV to 270mV

Table 2 - Test Limits De-Activation

Readings outside these limits indicate a failed TCAID.

3.4 Compare the two readings; the first shall be greater than the second by at least 50mV.

The PHASE A button can now be released.

4. Additional test for TCAID-D only

4.1 Using the TCAID tester turn the level control fully anti-clockwise. Press and hold down the PHASE B button, the display becomes active.

The button shall be held down for the duration of the first part of the test. If the display goes blank, the test shall be re-started from Step 4.1.

4.2 Slowly rotate the level control clockwise until it reaches, the fully clockwise position. If at any time, the TCAID operated symbol appears on the display, the TCAID-D has failed the test and shall be considered faulty.

The PHASE B button can now be released.

5. Reconnection of the TCAID

5.1 When the TCAID has passed all the tests, the tester shall be disconnected and then the disconnection links individually moved back and secured in the closed-circuit position, starting from the top downwards.

5.2 Close and lock the disconnection box.

END

Includes:	Single arm (Cautor) and Double arm (Forfex) types
Excludes:	Any other type of mechanical or electronic treadle

This requires possession of the line, because connected control equipment activates. Re-set any effected controls after treadle timing (e.g. automatic level crossings).

The timing adjustment screw may be used to adjust the time. Do not over-tighten or remove the screw from the dashpot.

TESTS

1. Single Arm Treadles

1.1 Bridge out the normally made contacts with a meter set to mA.

1.2 Depress, release and time the movement of the operating arm to the normal position.

1.3 Check the time and adjust if required.

The time is normally 6-8 seconds but can vary at certain installations, refer to the diagrams.

1.4 Remove the meter bridging connection.

2. Double Arm Treadles

2.1 Bridge out the normally made contacts with a meter set to mA.

2.2 Depress and hold down operating arm ‘1’.

2.3 Depress, release, and time the movement of the operating arm ‘2’ to the normal position.

2.4 Check the time and adjust as required.

The time is normally 6-8 seconds but can vary at certain installations, refer to the diagrams.

Adjust arm 2 adjustment screw, as shown in Appendix A.

2.5 Repeat the procedure for the other arm, i.e. hold down arm ‘2’ whilst timing arm ‘1’.

2.6 Depress both arms fully and release simultaneously. The time between simultaneously releasing the arms and the point at which the control rod falls to the bottom of the ‘V’ shall be within 6 to 10 seconds, regardless of the order in which the arms are lowered.

a) If either of the values is lower (or higher) than this, screw up (unscrew) the adjustment screw for the last arm lowered (arm 2 for direction 1 to 2).

b) If both values are lower (or higher) adjust both of the screws.

2.7 Remove the meter bridging connection.

APPENDIX A - Timing Adjustments

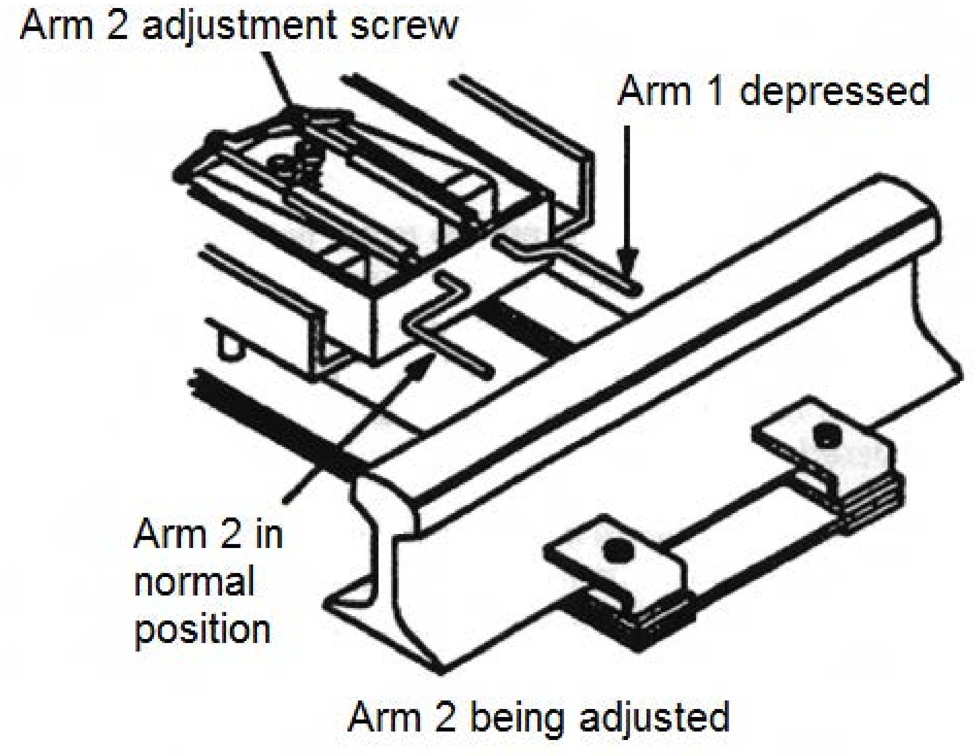

Figure 1 - Timing Adjustments on a Double Arm Treadle

END

Includes:	All AzLM Rail Contacts
Excludes:	All other types of AzL Rail Contact

GENERAL

Functional tests using the dummy wheel shall require relevant protection/possession arrangements and liaison with the Signaller.

These tests are required when the rail contacts are moved or re-aligned. They also usually form part of the annual test of axle counters.

Refer to NR/SMS/Appendix/15 (General Information on the Thales Axle Counter Systems) for additional system details.

All measurements are to be recorded on the appropriate paper or digital record card.

1. SK30H Dummy Wheel Positioning

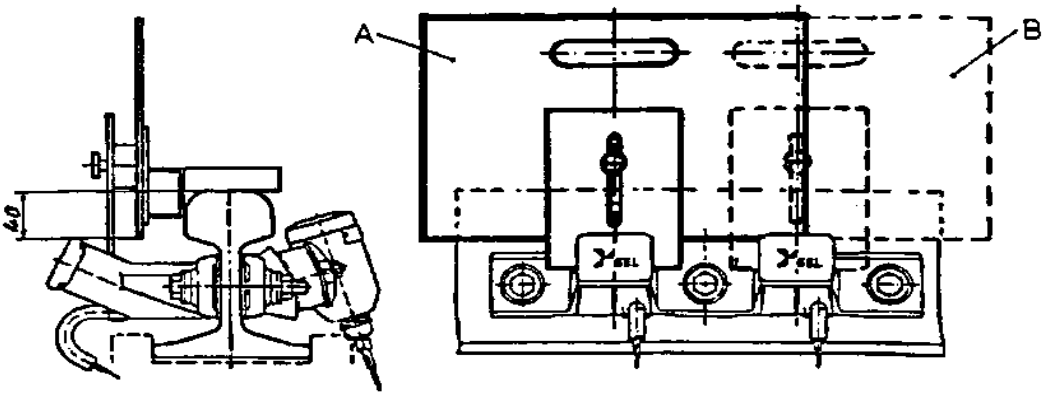

Figure 1 - Position of Dummy Wheel during Testing SK30H

Figure 1 left hand diagram shows a side on view and the right shows the dummy wheel placed over rail contacts SK1(marked A) and over SK2 (marked B).

2. SK30K Dummy Wheel Positioning

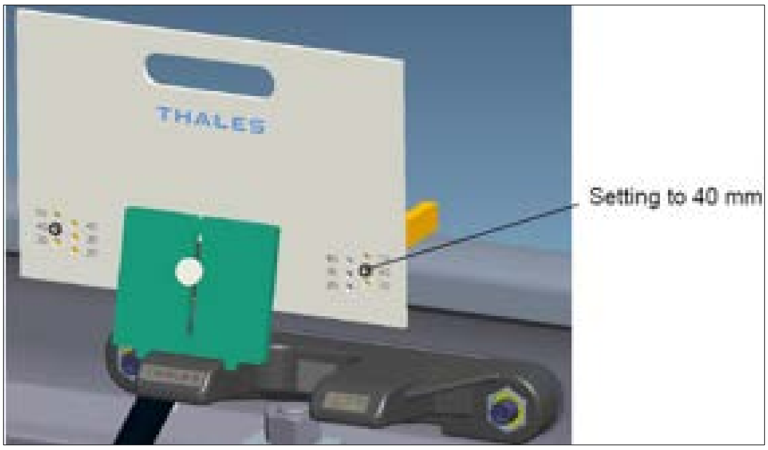

Figure 2 - Position of Dummy Wheel during Testing SK30K

3. All Rail Contacts

To simulate a wheel on an axle counter a dummy wheel supplied by the manufacturer is used. It consists of a metal plate with three plastic brackets.

The bottom edge of the plate is to be adjusted to 40mm for all double rail contacts.

The two brackets are swung out 90° to the metal plate and rest on the top rail.

The third bracket is flat and parallel to the metal plate. It holds the metal plate in the correct position by resting on one of the Rx coils to influence a count head

If it is required to simulate several wheels passing over the rail contacts, loosen the knurled nut and raise the flat bracket so that it is clear of the Rx coils while the device is passing over the heads.

The cut out notch on the third bracket should be aligned with the center mark on the received head when readings are being taken.

4. General Information Relating to SK30H Count Heads

The detection points for AzLM axle counters are fitted with a circuit to detect “drift” in each of the rail contacts.

On earlier versions of the Analogue card and ACE software a problem was identified where drift warnings can become stuck and continue to be reported after the fault has been cleared.

These faults are characterized by the History file downloaded from the Evaluator showing repeated, identical drift warnings every 5 minutes. This is no longer a requirement from ACE software version 6.1.3.

It is possible to fit an SK30K to an EAK30H with a new analogue card.

The SK30K has no mechanical setup and is set up using the potentiometers in the EAK only.

The set-up procedure can cause the associated sections (s) to become disturbed. Therefore, the appropriate protection/possession shall be agreed prior to work commencing

The dummy wheel 3JA 84532 AAAA is suitable for all rail contacts, Sk30, Sk30H and Sk30K

The former dummy wheel 19982 3100x is NOT suitable for Sk30K rail contacts.

5. Set up Procedure for EAK 30 H with SK30H:

A tested ESD strap shall be used to prevent damage to PCB's.

The three M12 rail mounting bolts shall be torqued to 45Nm.

5.1 Before making any adjustments to the SK30H: Using a multi-meter set to ohms, measure the resistance between each of the rail mounted RX heads and the running rail, and RX heads to the M12 bolts. If the resistance is below 2M ohms the rail mountings need to be cleaned or replaced

5.2 Check that the Evaluator (Digital) and analogue cards are fully home in the EAK sub rack if applicable.

5.3 Plug in the Thales 'Axle Counter Test Box' to the EAK.

5.4 Check that the cable cores on the power cable are twisted together. Also check that each Tx and Rx cable have their respective cores twisted together to the point 25mm of termination point.

Select switch position 3 on the test box to measure stabilised power channel 1 and switch position 4 to measure stablised power channel 2 and check they are both between 22Vdc and 35Vdc. If either of them is out of this range then there is a potential fault with the analogue card and this shall be replaced.

Inside the `Axle Counter Test Box`, select switch position 10, SK1 Received Rectified Voltage (+ve MESSAB 1) which shall be between +80 mV DC and +1000mV DC.

Place the dummy centrally over RX1 and measure –ve MESSAB 1, which shall be between -80 mV DC and -1000mV DC i.e. with the same amplitude but opposite polarity as the received rectified signal with no dummy wheel present (+ve MESSAB 1).

5.5 Compare the reading taken in step 4 and 5 these shall be within 10mv of each other (+ve MESSAB 1 shall be slightly higher), if it is proceed to step 5.13.

5.6 Reset the potentiometer R2 until the voltage +ve MESSAB 1 has its greatest value.

5.7 Undo the M8 nuts and adjust the TX head up / down until +ve MESSAB 1 and –ve MESSAB 1 are as near the same amplitude as possible. The +ve MESSAB shall be higher than the –ve MESSAB.

5.8 The rail contactor shall not touch the head of the rail.

5.9 The M8 nuts shall be re-tightened to a Torque setting of 25Nm.

5.10 If, after adjusting the TX head, the difference between +ve MESSAB 1 and –ve MESSAB 1 is more than 10mv then adjust R2 until +ve MESSAB 1 and –ve MESSAB 1 are within 10mv.

5.11 Check the +ve MESSAB is higher than the-ve MESSAB.

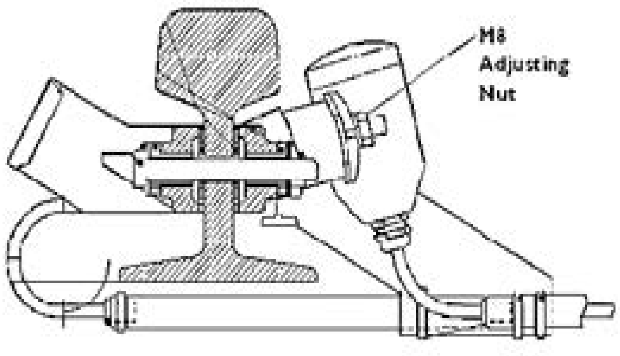

Figure 3 - SK30H M8 Adjustment nuts

5.12 Inside the `Axle Counter Test Box`, select switch position 11, reference voltage (PEGUE 1). Adjust potentiometer R1 (PEGUE 1) so that the reading is equal to +ve MESSAB 1 +/- 2%.

5.13 Check that that green LED H1/2 is flashing continuously.

5.14 Inside the `Axle Counter Test Box`, select switch position 12, SK2 Received Rectified Voltage (+ve MESSAB 2) which shall be between +80 mV DC and +1000mV DC.

5.15 Place the dummy centrally over RX2 and measure –ve MESSAB 2, which shall be between -80 mV DC and -1000mV DC i.e. with the same amplitude but opposite polarity as the received rectified signal with no dummy wheel present (+ve MESSAB 2).

5.16 Compare the reading taken in step 14 and 15 these shall be within 10mv of each other (+ve MESSAB 2 shall be slightly higher), if it is proceed to step 5.24

5.17 Reset the potentiometer R4 until the voltage +ve MESSAB 2 has its greatest value.

5.18 Undo the M8 nuts and adjust the TX head up / down until +ve MESSAB 2 and –ve MESSAB 2 are as near the same amplitude as possible. The +ve MESSAB shall be higher than the –ve MESSAB.

5.19 The rail contactor shall not touch the head of the rail.

5.20 The M8 nuts shall be re-tightened to a Torque setting of 25Nm.

5.21 If, after adjusting the TX head, the difference between +ve MESSAB 2 and –ve MESSAB 2 is more than 10mv then adjust R4 until +ve MESSAB 2 and –ve MESSAB 2 are within 10mv.

5.22 Check the +ve MESSAB is higher than the-ve MESSAB.

5.23 Inside the `Axle Counter Test Box`, select switch position 13 reference voltage (PEGUE 2).

5.24 Adjust potentiometer R3 (PEGUE 2) so that the reading is equal to +ve MESSAB 2 +/- 2%.

5.25 Check that green LED H2/2 is flashing continuously.

5.26 Measure the voltage and frequency of SK1 and SK2.

* Range (A): Analogue cards before version 3CR 01836 AEAA.

** Range (B): Analogue cards including and after version 3CR 01836 AEAA.

Test	Terminals	Range (A) *	Range (B) **
SK1 Voltage	Sk1/S1	40V to 64V AC	40V to 85V AC
SK1 Freq.	Sk1/S2	30 to 31.25kHz	29.8 to 31.3kHz
SK2 Voltage	Sk2/S1	40V to 64V AC	40V to 85V AC
SK2 Freq.	Sk2/S2	27.4 to 28.6kHz	26.8 to 28.6kHz

Table 1 - The Voltage and Frequencies Ranges of the Rail Contacts

6. Setting up and Adjustment of EAK 30H with SK30K Count Heads

A tested ESD strap shall be used to prevent damage to PCB's.

The two M12 rail mounting bolts shall be torqued to 58Nm.

6.1 Check that the Evaluator (Digital) and analogue cards are fully home in the EAK sub rack if applicable.

6.2 Plug in the Thales 'Axle Counter Test Box' to the EAK.

6.3 Check that the cable cores on the power cable are twisted together. Also check that each Tx and Rx cable have their respective cores twisted together to the point 25mm of termination point.

6.4 Check the silica / desiccant bag is not saturated with water and is fitted to each EAK.

6.5 Select switch position 3 on the test box to measure stabilised power channel 1 and switch position 4 to measure stablised power channel 2 and check they are both between 22Vdc and 35Vdc. If either of them are out of this range then there is a potential fault with the analogue card and this shall be replaced.

6.6 Inside the `Axle Counter Test Box`, select switch position 10, SK1 Received Rectified Voltage (+ve MESSAB 1) which shall be between +80 mV DC and +1000mV DC.

6.7 Place the dummy centrally over RX1 and measure –ve MESSAB 1, which shall be between -80 mV DC and -1000mV DC i.e. with the same amplitude but opposite polarity as the received rectified signal with no dummy wheel present (+ve MESSAB 1).

6.8 If the difference between +ve MESSAB 1 and –ve MESSAB 1 is more than 10mv then adjust R2 until +ve MESSAB 1 and –ve MESSAB 1 are within 10mv.

6.9 Check the +ve MESSAB is higher than the-ve MESSAB.

6.10 Inside the `Axle Counter Test Box`, select switch position 11, reference voltage (PEGUE 1). Adjust potentiometer R1 (PEGUE 1) so that the reading is equal to +ve MESSAB 1 +/- 2%.

6.11 Check that that green LED H1/2 is flashing continuously.

6.12 Inside the `Axle Counter Test Box`, select switch position 12, SK2 Received Rectified Voltage (+ve MESSAB 2) which shall be between +80 mV DC and +1000mV DC.

6.13 Place the dummy centrally over RX2 and measure –ve MESSAB 2, which shall be between -80 mV DC and -1000mV DC i.e. with the same amplitude but opposite polarity as the received rectified signal with no dummy wheel present (+ve MESSAB 2).

6.14 If the difference between +ve MESSAB 2 and –ve MESSAB 2is more than 10mv then adjust R4 until +ve MESSAB 2 and –ve MESSAB 2 are within 10mv.

6.15 Check the +ve MESSAB is higher than the-ve MESSAB.

6.16 Inside the `Axle Counter Test Box`, select switch position 13, reference voltage (PEGUE 2). Adjust potentiometer R3 (PEGUE 2) so that the reading is equal to +ve MESSAB 2 +/- 2%.

6.17 Check that green LED H2/2 is flashing continuously.

6.18 Measure the voltage and frequency of SK1 and SK2.

* Range (A): Analogue cards before version 3CR 01836 AEAA.

** Range (B): Analogue cards including and after version 3CR 01836 AEAA.

Test	Terminals	Range (A) *	Range (B) **
SK1 Voltage	Sk1/S1	40V to 64V AC	40V to 85V AC
SK1 Freq.	Sk1/S2	30 to 31.25kHz	29.8 to 31.3kHz
SK2 Voltage	Sk2/S1	40V to 64V AC	40V to 85V AC
SK2 Freq.	Sk2/S2	27.4 to 28.6kHz	26.8 to 28.6kHz

Table 2 - The Voltage and Frequencies Ranges of the Rail Contacts

7. Setting up and Adjustment of EAK 30K with SK30K Count Heads

A tested ESD strap shall be used to prevent damage to PCB’s.

The molded TX cable is always connected to SK1 inside the rail sensor if the direction needs to be change this can be achieved be adjusting the ARD plug (X600).

EAK Switches

The switches S1 and S2 shall be set to position 1 to activate the electrical adjustment. S3 should be set to H (For High), see Figure 4.

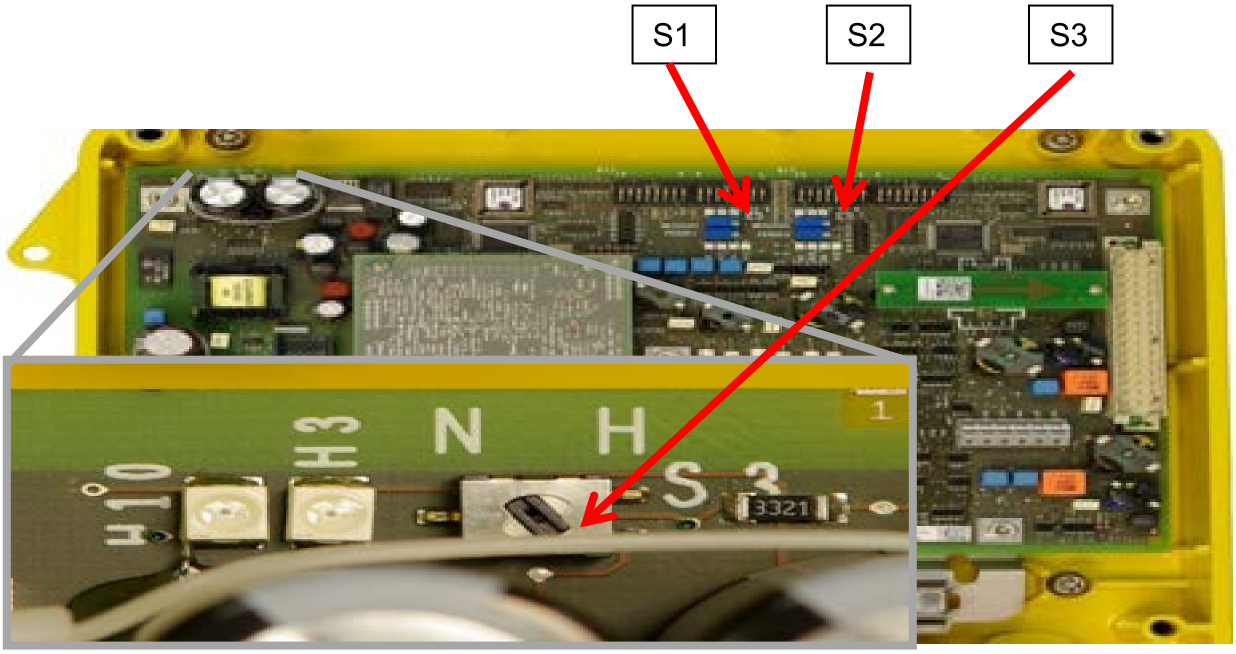

Figure 4 – Inside of the EAK

7.1 Check that the cable cores on the power cable are twisted together. Also check that each Tx and Rx cable have their respective cores twisted together to the point 25mm of termination point.

7.2 Check the silica / desiccant bag is not saturated with water and is fitted to each EAK.

7.3 Select switch position 3 on the test box to measure stabilised power channel 1 and switch position 4 to measure stablised power channel 2 and check they are both between 22Vdc and 35Vdc. If either of them is outside of this range then there is a potential fault with the analogue card and this shall be replaced.

7.4 Inside the `Axle Counter Test Box`, select switch position 10, SK1 Received Rectified Voltage (+ve MESSAB 1) which shall be between +80 mV DC and +1000mV DC.

7.5 Place the dummy centrally over RX1 and measure –ve MESSAB 1, which shall be between -80 mV DC and -1000mV DC i.e. with the same amplitude but opposite polarity as the received rectified signal with no dummy wheel present (+ve MESSAB 1).

7.6 If the difference between +ve MESSAB 1 and –ve MESSAB 1 is more than 10mv then adjust R2 until +ve MESSAB 1 and –ve MESSAB 1 are within 10mv.

7.7 Check the +ve MESSAB is higher than the-ve MESSAB.

7.8 Inside the `Axle Counter Test Box`, select switch position 11, reference voltage (PEGUE 1). Adjust potentiometer R1 (PEGUE 1) so that the reading is equal to +ve MESSAB 1 +/- 2%.

7.9 Check that green LED H1 is flashing continuously.

7.10 Inside the `Axle Counter Test Box`, select switch position 12, SK2 Received Rectified Voltage (+ve MESSAB 2) which shall be between +80 mV DC and +1000mV DC.

7.11 Place the dummy centrally over RX2 and measure –ve MESSAB 2, which shall be between -80 mV DC and -1000mV DC i.e. with the same amplitude but opposite polarity as the received rectified signal with no dummy wheel present (+ve MESSAB 2).

7.12 If the difference between +ve MESSAB 2 and –ve MESSAB 2 is more than 10mv then adjust R4 until +ve MESSAB 2 and –ve MESSAB 2 are within 10mv.

7.13 Check the +ve MESSAB is higher than the-ve MESSAB.

7.14 Inside the `Axle Counter Test Box`, select switch position 13, reference voltage (PEGUE 2). Adjust potentiometer R3 (PEGUE 2) so that the reading is equal to +ve MESSAB 2 +/- 2%.

7.15 Check that green LED H2 is flashing continuously.

7.16 Measure the voltage and frequency of SK1 and SK2, see Table 3.

Test	Terminal Block X106	Terminal Block X106 with Rail Contact Adapter	Reading
SK1 Voltage	Black & White 1 & 2	1 & 3	40V to 85V AC
SK1 Freq.			29.8 to 31.3kHz
SK2 Voltage	Yellow & Brown 7 & 8	6 & 8	40V to 85V AC
SK2 Freq.			26.8 to28.6kHz

Table 3 - The Voltage and Frequencies Ranges of the Rail Contacts

END

High voltages are present in the camera housing, extreme caution shall be taken (See NR/SMS/ EL00 Hazards Associated with Electrical Supplies).

Always obtain permission of the signaller before lowering or adjusting the camera.

Check that the signaller is using the camera that is not under test.

General

Only the Marconi V327 camera has a Camera Control Unit (CCU).

At some locations this is positioned with the camera, which requires it to be lowered first to gain access to the unit, otherwise the CCU will be accessible in the camera rack in the equipment room.

Installations using CCD cameras (e.g. Grundig) and Marconi V332 or Pye super lynx will not have this unit.

Most installations will have a Video Relay and Test Unit (VRTU).

The signaller's controls will override any that are selected on the VRTU. If this unit is not provided connection will have to be obtained via the camera coaxial lead (this will disable the camera from the signaller's control) and function tests on the equipment will have to be performed from the monitoring point.

Equipment Required

- TV Monitor.
- Oscilloscope (Not required for CCD camera's) (A general purpose TV type is suitable).
- BNC leads and BNC 'T' connectors.

1. Maintenance Test

Installations with a combined CCU or CCD cameras and no VRTU

1.1 Connect the test equipment (monitor or oscilloscope) using the BNC leads and connectors to the test socket (were provided) or to the camera coax lead.

1.2 Obtain a picture on the monitor and trace on the oscilloscope by operation of the appropriate test switches (where provided) or by request to the signaller.

Installations with a separate CCU and a VRTU

1.3 Connect the test equipment (monitor and oscilloscope) using the BNC leads and connectors to the video test socket on the VRTU. Obtain a picture and trace by operation of 'On Test' and 'Picture' buttons.

Vidicon cameras require a period of time to 'warm up' before a picture or trace is obtained.

All Installations

1.4 Check (where provided) that on operation of the push buttons on the VRTU the internal illuminations function.

1.5 Check that 'In Use' indication illuminates when that particular camera is selected by the signaller.

1.6 Check (where provided) the operation of the shutter by use of the 'Shutter' button on the VRTU or by selection by the signaller.

1.7 Set the camera for night time viewing by operation of the 'Iris' button on the VRTU or by selection by the signaller. Check the picture remains in focus.

1.8 Examine the resolution (picture detail) in each corner and the centre of the picture.

Crossing fencing can be used the check the horizontal resolution and the running rails the vertical resolution.

If the picture resolution is not satisfactory, the electrical focus, beam or black level may require adjustment. Refer to Appendix B for details of these adjustments.

CCD cameras do not have these adjustments therefore the camera itself may have to be replaced to resolve any problems.

1.9 Set the camera back to daytime viewing by operation of the 'Iris' button or by selection by the signaller and Check the following items:

- The area of the crossing between the barriers is clearly defined.
- The road stop lines (where provided) are clearly visible.
- The crossing area is reasonably central in the picture without the presence of a skyline.
- The picture is complete and without any vertical or horizontal disturbance and is a good representation of the crossing scene.
- The field of view is not obstructed by the camera housing, screen wiper or shutter.
- There is not any streaking, flaring, ringing or negative image on any part of the picture.
- Moving objects do not smear and any small objects (e.g. children) are clearly discernible.

Some cameras are fitted with 'Fisheye' lenses that will give a greater view of the crossing area with a slight proportional distortion.

1.10 Operate the shutter on the camera and set the monitor contrast to maximum.

This will give an image of the Vidicon tube faceplate image burn. If this is found to be severe, arrangements should be made to replace the camera.

1.11 Lower the camera and open the housing. Check the following items (these tests are not applicable to CCD cameras):

- Correct operation of the lens motor by operation of the 'Iris' button or by request to the signaller.
- The settings of the iris are at f/5.6 for daytime and f/1.4 for night time.
- The lens motor limit switches and contact pillars are secure.
- When on night time setting the iris is fully open and does not obstruct the lens aperture in any way.
- When on daytime setting the iris is closed to a aperture of no smaller than 3mm diameter.

Take care when conducting these tests and do not touch the lens or the adjacent heater.

1.12 Close the camera housing and raise the camera.

1.13 Obtain a trace of the composite video signal on the oscilloscope. Check that the values of the signal components are as given in Appendix A. Adjustments to the signal components are given in Appendix B. No adjustments are possible on CCD cameras.

1.14 At the monitoring point check that a satisfactory picture is obtained on the signallers monitor (to correctly set up a monitor see Appendix C).
In liaison with the signaller check the following:

- A person standing at and walking between each corner of the crossing is clearly visible.
- The selections of lens and wiper controls are effective.
- The wiper when switched off parks correctly outside the field of view.
- Check that all functions work correctly on the alternative monitor.

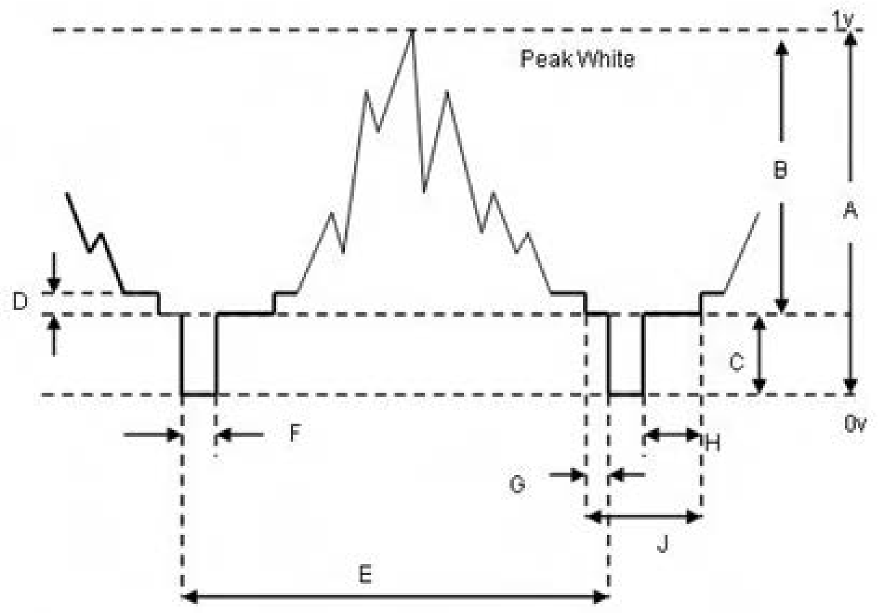
1.15 Repeat 1.1 to 1.14 for the other camera.

1.16 On completion of testing, check that on the VRTU the ‘On Test’ button is left deselected. If left selected the camera will always be ‘On’ even if it is not selected by the signaller.

1.17 Arrange for a check on the quality of the pictures from both cameras during the hours of darkness.

APPENDIX A

Composite Video Signal



A. Composite video signal 1v peak-to-peak (100%).

B. Video component of signal 0.7v (70%).

C. Sync component of signal 0.3v (30%).

D. Black Level 50mV.

E. Complete Line period 64µs

F. Line Synchronising pulse 5µs.

G. Front porch 1.5µs

H. Back porch 7µs

I. Line blanking interval 12µs.

The composite video signal consists of a video signal that has had synchronising pulses added. The ratio of amplitude of video to sync can vary but in the standard 1volt peak-to- peak composite video it is 70:30.

If the sync component of the signal is set at 0.3v then the maximum amplitude of the video will be 0.7v, so that the peak white is at the 1v level and correspondingly the bottom of the sync pulse is at 0v.

APPENDIX B

Focus Adjustment

Set the lens to infinity. Adjust mechanically the Vidicon racking (yoke focus adjusting screw and lock nut) lens screws or lens mount as appropriate.

Obtain the optimum focus by sliding the assembly forwards or backwards then retighten all the fastenings. Set the lens back to its original setting.

If a satisfactory focus cannot be achieved by this method, adjust the electrical focus on the camera or CCU in addition to the mechanical focus to obtain the optimum focus.

Beam Adjustment

This control adjusts the number of electrons forming the beam. Firstly, turn the control on the camera or CCU anti- clockwise to remove the entire picture.

Then slowly advance the control clockwise until all the picture detail including highlights (white portions of the picture) are clearly defined, then advance the control a further 30° or until the focus begins to deteriorate (whichever is sooner).

On the oscilloscope, the video component of the displayed signal should be 0.7v (70%) of the 1v peak-to-peak composite video signal.

Black Level Adjustment

This control affects the processing of the video signal from the target. It operates by cutting off any voltage below a certain level (Black).

It controls the DC level of the darkest part of the waveform with respect to the blanking level (sync pulse base line). It should be adjusted to be 50mV above the blanking level.

On a monitor, this should give detail in the darkest areas of the picture.

Target Bias Adjustment

This control sets the maximum electrical sensitivity of the vidicon tube. If it is set to high, it will allow rapid vidicon ‘image’ burn.

Adjust only with reference to the cameras manufacture’s manual

All adjustments need to be a compromise between correct voltage levels and optimum displayed picture.

APPENDIX C

Monitor Setting Up Procedure

1. Obtain a picture on the monitor. Check the pilot light (if fitted) is illuminated.

2. Set the Brightness and Contrast controls fully anti- clockwise.

3. Advance the Brightness control slowly clockwise until the raster is just visible.

   The raster is the structure of the scanning lines without a visible picture (on most monitors)

4. Advance the Contrast control slowly clockwise until a satisfactory picture is obtained with the highlight details still clearly visible.

   Note that the setting of these controls may vary between individual viewers.

5. Check that the monitor coaxial output is terminated with a 75Ω BNC terminating plug or (if provided) the switch is set to 75Ω.

6. Only where external controls are provided adjust the following to obtain a satisfactory picture:

   - Vertical Hold.
   - Horizontal Hold.
   - Focus.
   - Scan.
   - Sync.
   - Height.

If a satisfactory picture cannot be obtained on a monitor after setting up, it should be replaced. No attempt is to be made to make adjustments within the monitor housing.

End

ANALOGUE HIGH FREQUENCY SYSTEMS

There are several different types of High Frequency (HF) Transmission systems covered by this SMS. Conventional systems include Marconi, Rediffusion, and Philips. Phillips uses Frequency Modulation (FM) while the others use Amplitude Modulation (AM)).

Although the modulation differs between these makes, the principle of operation remains the same for all. The Baseband signal from a CCTV camera is very wideband ranging from 20Hz to over 5MHz.

This signal will not travel far along a cable before the high frequency portions attenuate leaving only the lower frequencies. Simple amplification cannot recover the distorted signal. If the distance between crossing and Signalbox is over 4Km the practice was to install a dedicated HF carrier system from one of the companies above.

The HF system reduces the problem from higher frequencies attenuating faster and makes the transmission system workable up to maximum distances around 30-50Km depending on the system used.

Line Amplifiers are still needed every 3-4Km to boost the signal. An oscilloscope is always needed to monitor both the HF and video signals. A TV monitor can only be connected where there is a “Demodulated” output. There is always a Demodulated output at the signal box end for the Signaller but most HF systems had no intermediate demodulated output at line amplifiers.

The exception is the Marconi HF system which used the same item of equipment as both a line amplifier and as the final “Demodulator” at the Signalbox.

On these systems there is a demodulated output available at each line amplifier that can be used for setting up and fault finding. Some systems have a simple LED indication on the front if the signal level being received is sufficient. This can generally be a help for tracing faults, but can be fooled in certain cases by excessive noise in the system.

Testing and fault finding should generally proceed from the TX end to the RX end. It is advisable to use a pattern generator for the tests on the transmission system rather than relying on a camera picture.

On these systems, the tests will require a possession of the CCTV system.

OPTICAL SYSTEMS

The Coe 300 system uses an optical fibre cable to link the transmitter and receiver of the system; the signals are transmitted by laser technology via a HF FM carrier at 400MHz.

Because of the technology of this system, it differs in its method of operation from the ‘conventional’ systems (no repeaters required for long distances) required for making the system more efficient and reliable and also requiring less maintenance.

GENERAL TEST EQUIPMENT REQUIRED FOR ALL CONVENTIONAL HF SYSTEMS

- Suitable multi-range meter.
- TV Monitor.
- Oscilloscope (Usually 20MHz Bandwidth, but Rediffusion Mk13 up to 50MHz)
- BNC leads and BNC ‘T’ connectors.
- 75ohms BNC terminator plug.
- Insulation tester.
- A monochrome TV pattern generator producing a 1V peak-to-peak/75Ω staircase video signal or similar.

When connecting the oscilloscope to take measurements, it should be done using the BNC ‘T’ piece and the 75Ω terminator plug.

MARCONI / GEC 14.5MHZ AM HF SYSTEM

Details of expected waveforms are in the typical voltage/waveform section.

1. Transmitter (Level Crossing) End

1.1 Check the supply voltage and ripple voltage from the power supply units to the modulator and (if fitted) launch amplifier:

a) Modulator voltage - 12vDC ±0.25V DC, Ripple voltage <50mV (pk-pk).

b) Launch Amp – 28V or 24V DC ±0.25V DC, Ripple voltage <50mV (pk-pk).

1.2 Check any LED indications are correctly illuminated. Power, Carrier etc.

1.3 Disconnect the camera input to the modulator and Check by means of the oscilloscope carrier output signal.

1.4 Connect the TV pattern generator to the modulator input and Check by means of the oscilloscope and/or the monitor the input signal.

1.5 Check by means of the oscilloscope the output signal from the modulator. Check there is no ripple present.

1.6 If fitted Check by means of the oscilloscope the output signal from the launch amplifier. Check there is no ripple present.

1.7 If any of the signals/waveforms are not as depicted in the appendices, the cause will be required to be investigated and rectified before proceeding with the test.

2. Line Amplifiers(s) (If Provided)

2.1 Check at each line repeater location the supply voltage and ripple voltage from the power supply unit to the Line amplifier and (if fitted) launch amplifier:

a) Line Amp - 12vDC ±0.25V DC, Ripple voltage <50mV (pk-pk).

b) Launch Amp – 28V or 24V DC ±0.25V DC, Ripple voltage <50mV (pk-pk).

2.2 Check any LED indications are correctly illuminated. Power, Carrier etc.

2.3 Check by means of the oscilloscope the input and output signal to/from the line amplifier and launch amplifier (if fitted). Check there is no ripple present.

2.4 If a video output socket is available, Check with the monitor the quality of the received video.

2.5 If any of the signals/waveforms are not as depicted in the appendices, the cause shall be investigated and rectified before proceeding with the test.

3. Receiver (Monitoring Point) End

3.1 Check the supply voltage and ripple voltage from the power supply unit to the Demodulator (Line amplifier):

a) Demodulator -+12V DC ±0.25V, Ripple voltage <50mV (pk-pk)

3.2 Check any LED indications are correctly illuminated. Power, Carrier etc.

3.3 Check by means of the oscilloscope and/or monitor the output signal of the demodulator.

3.4 If any of the signals/waveforms are not as depicted in typical voltages/waveforms table below and Appendix C, the cause shall be be investigated and rectified.

4. Final

4.1 At the transmission end of the system disconnect the pattern generator and re-connect the camera output to the modulator.

4.2 Check that the received picture at the monitoring point is of satisfactory quality.

Typical Voltages / Waveforms

Location	Voltage/Waveform
Input to modulator	1Vpk-pk composite video
Output from modulator	3V pk-pk (1V RMS) modulated
Output from launch amp	12Vpk-pk (4V RMS) modulated
Output from Line amp	3V pk-pk (1V RMS) modulated
Output from demodulator	1V pk-pk composite video

Table 1 – typical volumes/waveforms

PHILIPS FM HF SYSTEM EXTRA EQUIPMENT REQUIRED

- A monochrome TV pattern generator producing a staircase video signal and a Multiburst test pattern (both 1V peak-to-peak/75Ω signal).
- Portable Philips FM demodulator unit.

5 Transmission (Level Crossing) End

5.1 Check that the red LED on the power supply module is illuminated and the 'Carrier Fail' LED on the 'FM Rx' (demodulator) is extinguished.

5.2 Disconnect the camera input to the modulator and Check by means of the oscilloscope the unmodulated carrier signal at the FM output socket at the rear of the modulator frame (1V pk-pk ±0.1V undistorted sine wave at approximately 3.4MHz). Check there is no ripple present.

5.3 Connect the TV pattern generator set to a 'staircase' pattern to the modulator input and Check by means of the oscilloscope the input signal (Appendix C).

5.4 Check by means of the oscilloscope the modulated output signal of the modulator (Appendix C). Check there is no ripple present.

5.5 Check by means of the oscilloscope or TV monitor the output of the demodulated video test socket (Appendix C).

6 Transmitter End Launch Amplifiers (If Provided)

6.1 Switch the pattern generator to 'multiburst' and connect it to the launch amplifiers input socket. Connect the oscilloscope to the output socket (75ohms terminated) and Check the waveform.

Check the amplitude of the waveform increases linearly with frequency at each multiburst signal step (Appendix C). Check there is no ripple present.

6.2 Reconnect the modulator output to the launch amplifiers input and the output back to line.

7 Repeaters (If Provided)

7.1 Repeaters should not be adjusted during normal maintenance. However if adjustment is deemed necessary (low measurements at the receiver end), details on how to do this are contained in Appendix D.

8 Receiver (Monitoring Point) End

8.1 Check that the red LED on the power supply module is illuminated.

8.2 Check that with the transmission system operating normally (picture being transmitted) the 'Carrier Fail' LED on the 'FM Rx' (demodulator) module is extinguished. Disconnect the FM input and Check the LED illuminates.

8.3 Check by means of the oscilloscope the demodulated waveform at the 'Test Video O/P' socket (Appendix B).

8.4 Check a picture has been called.

8.5 Connect the monitor to the 'Processed Video O/P, socket. Check that a satisfactory picture is obtained. Check a picture has been called

8.6 Check the switch on the rear of the monitor is set to 'terminated'.

9 Final Checks

9.1 Check that all the cables in the system are correctly refitted and all test equipment is removed.

9.2 Check that the pictures obtained on the signaller's monitors are satisfactory.

COE 300 SYSTEM

Includes:	Earlier Coe 120 System
Excludes:	All other systems

This product contains a class 1 laser. There is no risk to eyesight in normal use. However use of a magnifying glass or a microscope to deliberately examine the laser output could be a hazard and shall not be attempted.

10 Transmitter End

10.1 Check that the Green Power LED Indication is lit and the Red Laser Alarm LED is out.

11 Receiver End

11.1 Check that the Green Video Detect LED Indication is lit and the Red Optical Alarm LED is out.

11.2 Check the received picture quality on the Signallers Monitor.

12 Testing Following Alterations

Whenever alterations have been carried out to the system which can affect the settings, such as a module replaced after failure or a repair to the fibre cable, then the following additional tasks shall be carried out.

12.1 Measure the voltage on the 12V Power supplies. These should be 12V ± 0.5V.

12.2 Using an oscilloscope to monitor the video output at the Signal box, terminated in 75 Ohms, adjust the "Video level Set" on the Receiver to give a Video output of 1V Pk to Pk while there is a signal of 1V Pk to Pk being input at the transmitter. Check the resulting picture on the Signallers Monitor.

APPENDIX A – Block Diagram of a Typical Generic Hf Tx System

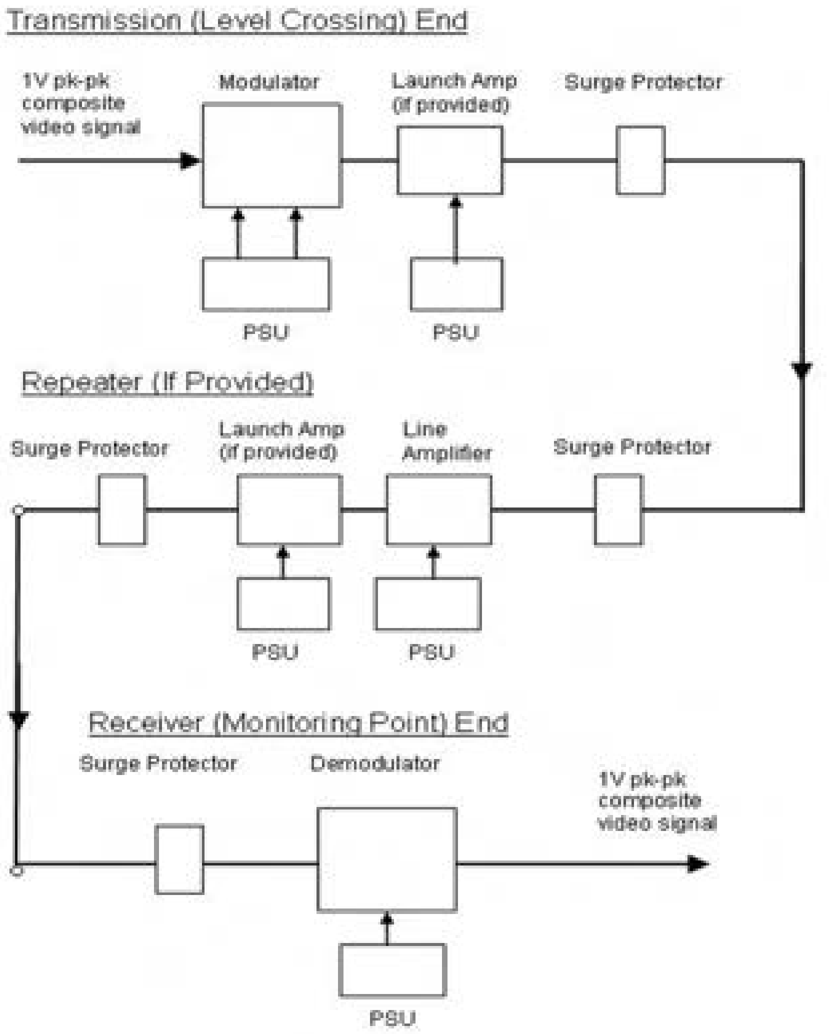


Figure 1 – Block Diagram of a Typical Generic HF TX System

APPENDIX B - Block Diagram of a Coe 300 System

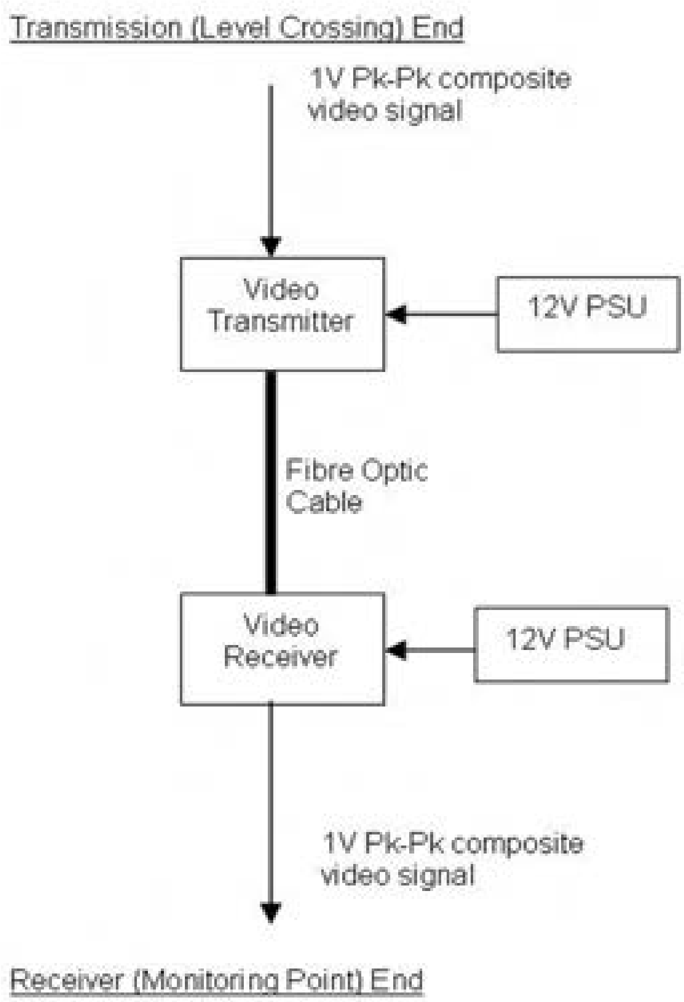

Figure 2 – Block Diagram of a Coe 300 System

APPENDIX C - Waveforms

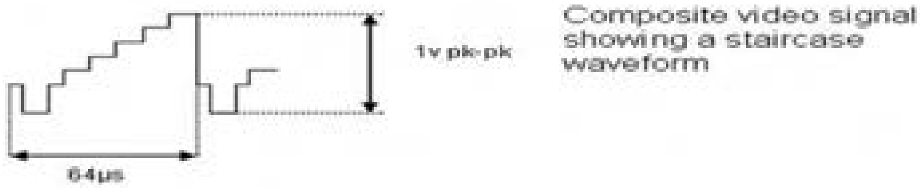

Figure 3 – Staircase waveform

Figure 4 – Staircase waveform (viewed on tv monitor)

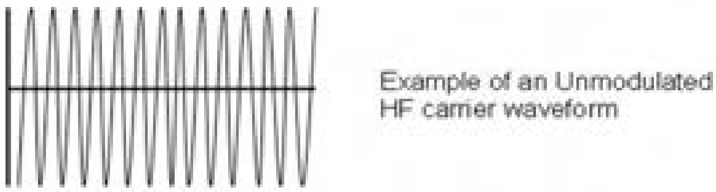

Figure 5 – Unmodulated HF carrier waveform

Figure 6 – Amplitude Modulated HF waveform

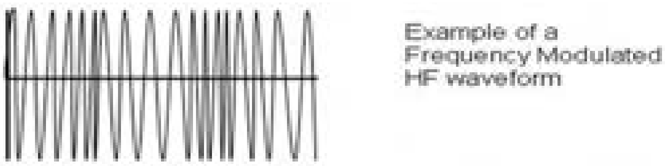

Figure 7 – Frequency modulated HF waveform

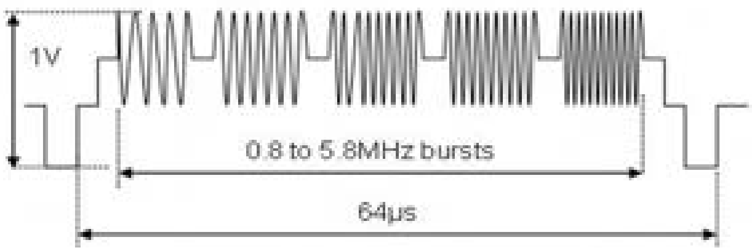

Figure 8 – Multiburst waveform

- The bursts are at 0.8, 1.8, 2.8, 3.8, 4.8 & 5.8MHz. Not all are shown on the diagram.
- The output from a launch amplifier can have the bursts increasing in amplitude linearly with each step from low to high frequency.

APPENDIX D - Repeaters on Philips FM Systems

Repeaters should only be tested or adjusted if deemed necessary by poor reception, if you are in doubt ask your SM(S).

It is important that the repeaters are tested in the correct order (from first to last). Note that a repeater amplifier is sometimes fitted at the demodulator location.

Testing

a. Isolate the coaxial cable between the repeater and transmission modulator (or previous repeater if not the first). Using a suitable meter (e.g. megger)

   Measure the DC loop resistance and insulation resistance of the cable (Inner to outer, inner to earth and outer to earth).

   - Use a test voltage of 500V.
   - Discharge any residual voltage on the cable after this test.

b. Reconnect the coaxial cable at both ends.

c. Check that the neon indicator on the front panel on/off rocker switch is illuminated.

d. At the previous location in the system, (transmission modulator or repeater) connect the pattern generator set to multiburst to the equipment side of the outgoing surge protection module.

   At the repeater under test, connect the oscilloscope to the 'Video Output' (75Ω terminated) socket of the repeater.

e. Check the waveform (Appendix B) and the waveform amplitude (1V pk-pk). If it is not correct, the repeater can be adjusted to achieve a uniform frequency response and signal amplitude (C 11). Check there is no 50 or 100Hz ripple on the waveform.

   TI21 audio frequency track circuits can cause interference on the waveform.

f. At the previous location, set the pattern generator to staircase.

g. Measure using the oscilloscope the FM signal level at the output of the repeater (1V pk-pk). Adjust the repeaters 'Set Gain' control if necessary.

h. Connect the portable demodulator and monitor to the output of the repeater. Check that a satisfactory picture is obtained.

   - The monitoring signal box will have to call a picture via the signaller's controls.

- The picture quality can deteriorate slightly on the output of each successive repeater.

- Check that the switch on the rear of the monitor is set to ‘terminated’.

i. Reconnect all cabling at the repeater for normal working.

j. Repeat a) to i) for all other repeaters in the system.

Adjustment

- Set all the controls (Set Gain, HF1, LF, HF2, MF, HF3) fully counter clock wise.

- Adjust the Set Gain control to give approximately 0.3V sync pulse amplitude.

- Adjust LF to eliminate ‘tilt’ in the signal (e.g. the front and back porch of the sync pulse at the same DC level).

- Adjust MF gain to set 0.8MHz burst to approximately 0.7V.

- Adjust HF2, HF1 and HF3 to give overall a 0.8 to 5.8MHz multiburst level of 0.7V, as flat as possible.

- Make small adjustments, if necessary to MF and Set Gain to set the overall signal amplitude to 1V pk-pk.

End

General

You shall always obtain permission of the Signaller before accessing or adjusting the camera. On duplicated systems Check that the signaller is using the camera that is not under test.

Installations have a Video Relay and Test Unit (VRTU). The signaller's controls can override any that are selected on the VRTU.

Equipment Required

- Colour TV Monitor.
- Oscilloscope (a general purpose TV type is suitable).
- BNC leads and BNC 'T' connectors.

1. Maintenance Test

1.1 Connect the test equipment (monitor and oscilloscope) using the BNC leads and connectors to the video test socket on the VRTU. Obtain a picture and oscilloscope trace by operation of 'On Test' and 'Picture' rocker switches on the VRTU.

The monitor and oscilloscope shall be connected in a 'daisy chain' arrangement, with the last item in the chain terminated in 75Ω. This is easiest done with the monitor as the last item in the chain.

1.2 Check that upon operation of the push buttons on the VRTU, the indication lights function.

1.3 Check that the 'In Use' indication illuminates when that particular camera is selected by the Signaller.

1.4 Examine the resolution (fine picture detail) of the picture.

For example, use vertical fencing or railings for checking horizontal resolution and horizontal sleepers for checking vertical resolution.

If the picture resolution is not satisfactory, the camera itself may have to be replaced to resolve any problems.

1.5 Check the following items:

a) The red tail lamps at the rear of all trains stopped at the platform are clearly visible.

b) The red tail lamps of non-stop trains are clearly visible.

c) The tail lamp area of stationary trains reasonably central in the picture and that there is little (if any) sky visible in the picture.

d) The picture is complete and without any vertical or horizontal disturbance, or patterning and is a good representation of the actual scene.

e) The field of view is not obstructed by the camera housing, screen wiper or shutter.

f) There is no streaking, flaring, ringing or negative image on any part of the picture.

If necessary, the lens focus and focal length settings can be adjusted, as shown in Appendices B & C.

If two cameras are provided they can have different ‘zoom’ lens focal length settings, to allow clear views of trains of differing lengths.

1.6 Access the camera and open the housing. Check the following items:

a) The locking screws for the lens iris and focal length adjusting rings are tight.

b) The 15-way “D” type and BNC connectors are securely mated with the camera.

c) The plug at the end of the cable coming from the lens/lens iris drive adaptor is securely mated with the camera.

d) The camera is securely fixed in position within the weatherproof housing.

Care shall be taken when conducting these tests not to touch the front of the lens or the adjacent screen demisting heater.

1.7 Close up the camera housing.

1.8 Obtain a trace of the composite video signal on the oscilloscope. Check that the values of the signal components are as given in Appendix A.

No adjustments are possible on CCD cameras.

1.9 At the monitoring point Check that a satisfactory picture is obtained on the Signallers monitor in use in liaison with the signaller, check the following:

a) The tail lamps of trains are clearly visible.

b) The wiper controls are effective.

c) The wiper when switched off parks correctly outside the field of view.

d) Check all functions work correctly on the alternative monitor.

To correctly set up a monitor see Appendix D

1.10 If provided, repeat 1.1 to 1.9 for the other camera.

1.11 On completion of testing, check that on the VRTU the ‘On Test’ button is left deselected.

If left selected the camera is always 'ON' even if it is not selected by the signaller.

Arrange for a check on the quality of the pictures from both cameras during the hours of darkness.

APPENDIX A - Composite Video Signal

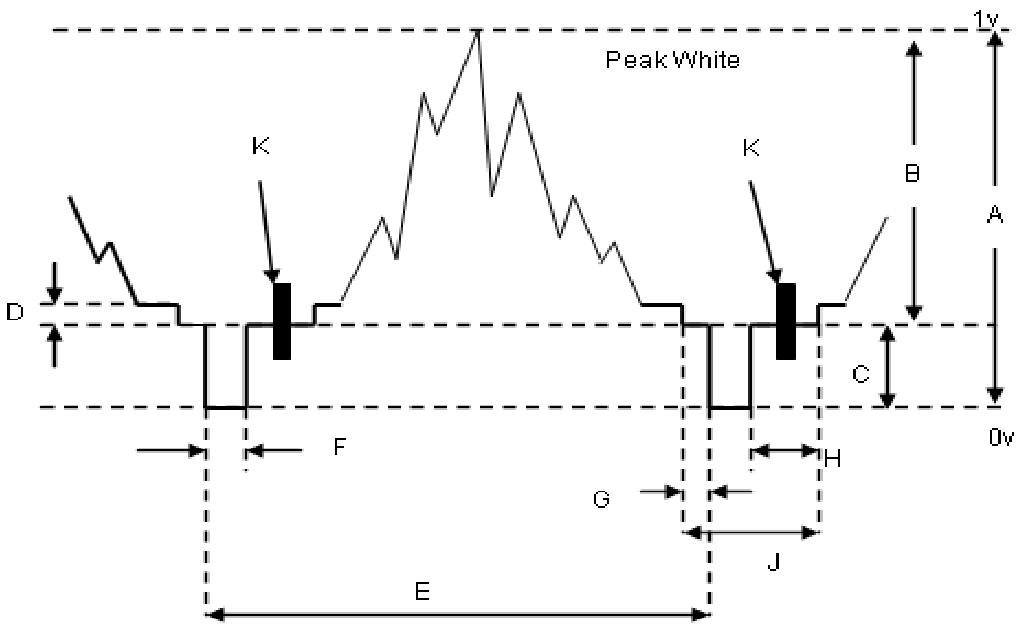

Figure 1 – Composite Video Signal

- A: Composite video signal 1v peak-to-peak (100%).
- B: Video component of signal 0.7v (70%).
- C: Sync component of signal 0.3v (30%).
- D: Black Level 50mV (approximate).
- E: Complete Line period 64μs.
- F: Line synchronising pulse 5μs.
- G: Front porch 1.5μs.
- H: Back porch 7μs.
- J: Line blanking interval 12μs.
- K: Colour burst (a 4.43MHz sinewave) signal

The composite video signal consists of a video signal that has had synchronising pulses added.

The ratio of amplitude of video to sync can vary but in the standard 1volt peak-to-peak composite video it is 70:30.

If the sync component of the signal is set at 0.3v then the maximum amplitude of the video can be 0.7v, so that the peak white is at the 1v level and correspondingly the bottom of the sync pulse is at 0v.

APPENDIX B - Lens Optical Focus Adjustment

Slacken the locking screw on the lens focus ring and slowly adjust (rotate) the focus ring to give a sharp image of the rear of trains standing at the platform.

Tighten the locking screw.

APPENDIX C - Lens Focal Length (zoom) adjustment

Slacken the locking screw on the lens focal length ring and slowly adjust (rotate) the ring to give the correct area of view.

The ring white reference line on it and the adjacent scale is marked in several focal length settings (millimetres).

It can also be necessary to adjust the optical focus ring in order to retain a well-focussed picture.

The ‘zoom’ setting of each camera can be different, in order to give the best view of tails lamps, for trains of varying lengths.

Tighten the locking screw.

APPENDIX D - Monitor Setting up Procedure

This applies to ‘TEW’ TFT LCD types only, details on other type monitors can be found in NR/SMS/Test/046 Appendix C

1 Obtain a picture on the monitor. Check the ‘pilot’ light is illuminated.

2 Call up the on-screen menu. Set the Brightness and Contrast controls ranges to minimum (zero).

3 Advance the Brightness level until the screen is just illuminated.

4 Advance the Contrast level slowly until a satisfactory picture is obtained with the highlight (brightest areas) details still clearly visible.

The setting of these controls can vary between individual viewers.

Call up the sharpness adjustment and set it to give a picture with sharp vertical trailing edges.

Excessive use of sharpness can cause a “black after white” effect.

5 Check that, on the monitor with two coaxial leads connected (usually Monitor 1), the small “slider” switch by the BNC sockets is set to “bridged” and that on the other monitor (usually Monitor 2), the switch is set to the “terminated/75Ω” position.

It should not be necessary to adjust any other setting in the monitor’s ‘on screen’ menu system If a satisfactory picture cannot be obtained on a monitor after setting up, it shall be replaced.

No attempt shall be made to make adjustments within the monitor housing.

The plastic screen on TFT monitors should only be cleaned in accordance with the manufacturer’s recommendations. Use of inappropriate cleaning materials (cloths, liquids and sprays) can cause permanent damage to it.

END

Includes:	Ultra If the Circuit Contact Box
Excludes:	All other types of Circuit controller box

Contact Setting procedure

1. Secure the inclinometer to the barrier.

2. Connect a suitable buzzer or meter across the micro-switch under adjustment.

3. Lift and hold the barrier at the desired angle.

4. Rotate the cam until the switch contacts just make.

5. Secure the cam on the lever shaft by torque tightening the first grub screw at 3.0 to 3.5 Nm.

   Raise or lower the barrier to gain access to the second grub screw and repeat the tightening procedure.

   It may be necessary to temporarily disconnect the barrier from the barrier box lever to gain access to the second grub screw.

6. Only tighten 2 out of the 3 grub screws for each cam.

7. Apply firm thumb pressure to each cam to confirm security to the lever shaft.

8. Check the switch operating correctly? If it is move to step 10.

9. If the switch is making when it should be breaking, loosen the grub screws and go back to step 3 using other contact slope on the cam.

10. Does the switch make at the correct angle? If not refer to the table below for fine tuning adjustments.

    The fine adjustment screw should be adjusted in increments of ¼ turn or less.

11. Repeat the process in flowchart 1 until satisfactory results are obtained.

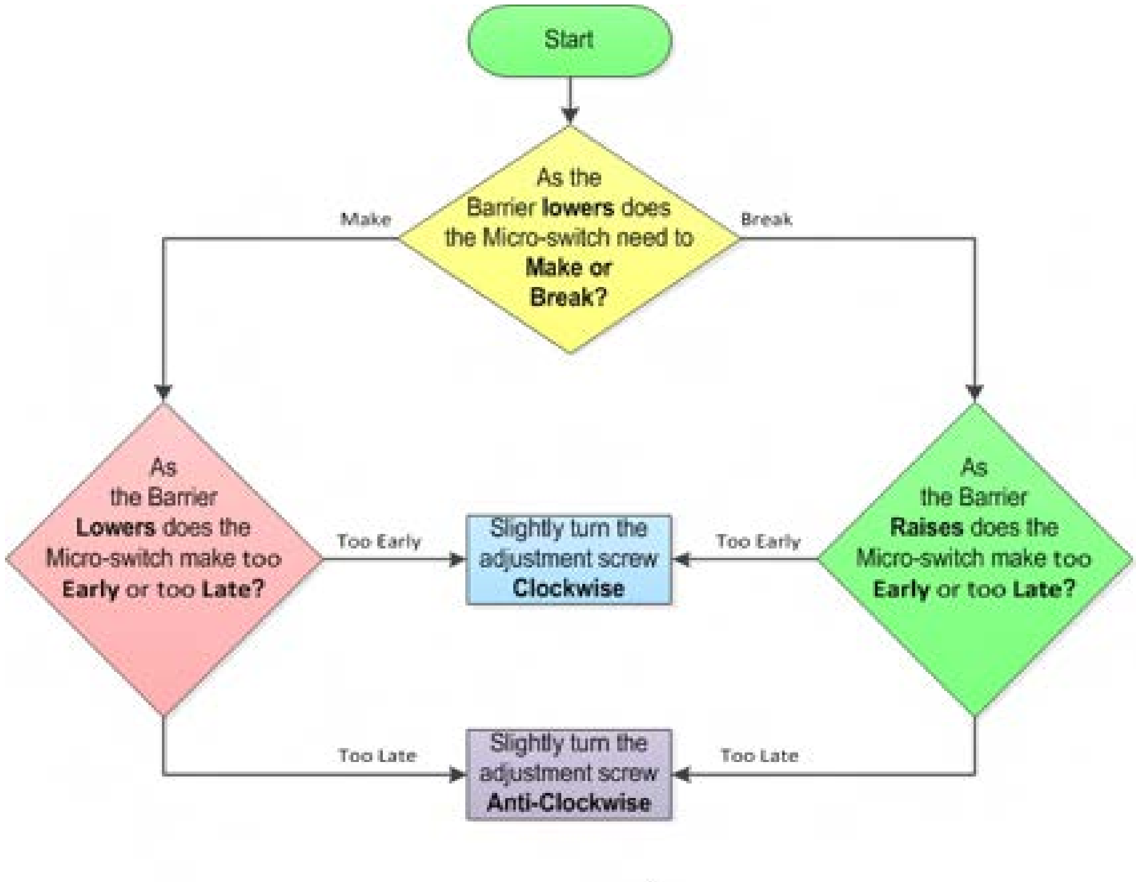
12. If satisfactory results cannot be gained, reset the fine adjustment screw to mid position as follows:

    a) Fully tighten the fine adjustment screw such that the switch mounting plate is in contact with the brass spacer.

    b) Slacken the adjustment screw by one and one quarter (1¼) full turns.

    c) The switch should now be at mid position of its fine adjustment.

    d) Slacken the two grub screws securing the cam to the lever shaft & return to step 3.



Flowchart 1 – Micro-switch adjustment process

13. Once a satisfactory result has been achieved for the micro-switch, repeat the above procedure for all remaining micro-switches.

End

Includes:	Busbar Earth Tests
Excludes:	All Busbar fitted with an Electronic Monitoring Device.

The tests require to be carried out on busbars that do not exceed a nominal 110V AC or 120V DC.

General

These tests are not normally required on equipment that is continuously monitored; see NR/SMS/PartC/EL00 - Electrical Equipment General, for further details. If you are in doubt, ask your SM(S).

The definition 'busbar' includes all power fed from a supply to equipment/circuits.

Signalling Circuits that are Intentionally Connected to Earth

These circuits (e.g. earth return circuits) do not need testing by the methodology in this test. If a second earth fault occurs, the affected circuit might not operate or operate irregularly indicating the problem.

Earth Values

Earth test values are detailed in NR/SMS/PartZ/Z07 – Earth Leakage Reference Values.

The reportable earth test result is the value that should be reported to your SM(S).

The maximum acceptable earth test result relates to the minimum insulation value that a signalling circuit is expected to meet to continue to operate safely.

The safety maximum earth test result relates to an insulation value, less than the acceptable value, below which the margin of safety provided is considered inadequate for the continued safe operation of the signalling equipment.

Investigation of Earth Faults

There is a zero tolerance to earth faults outside the defined acceptable limits across the network.

Report all test results indicating earth problems, at any level, to your SM(S), to be dealt with as detailed in NR/SMS/PartC/EL21 – Trackside Apparatus Case and NR/SMS/PartC/EL31 - Equipment and Relay Rooms.

1 DC Earth Test up to a Nominal 120V

Use a calibrated electronic meter with an input impedance of >1MΩ fitted with a 150kΩ shunt.

1.1 Measure the busbar voltage, record the results.

1.2 Connect one meter lead to the positive busbar, the other to earth, record the voltage (V1) – ignore polarity.

1.3 Connect one meter lead to the negative busbar, the other to earth, record the voltage (V2) – ignore polarity.

1.4 Disconnect the meter and compare the results with the safety values detailed in NR/SMS/PartZ/Z07 - Earth Leakage Reference Values.

If the required busbar voltage is not shown, use the next available lower voltage.

1.5 Investigate any readings that are outside the required values shown in the tables in Part Z. Any investigations shall be reported to your SM(S).

2 AC Earth Test up to a Nominal 110V

Use an electronic meter with an input impedance of >1MΩ (Do not use the 150kΩ shunt). Also use the AC busbar earth test adapter.

2.1 Connect the meter set to volts dc to the red and one of the black terminals of the earth test adapter.

2.2 Connect the green and other black terminal of the earth test adapter together and record the battery voltage (Vb). Renew the battery if the reading is less than 8V.

2.3 Connect the green terminal to earth and the black terminal to either the BX or NX busbar. Record voltage V1.

2.4 Reverse the leads to the same busbar (i.e. the black lead connected to earth and the green to the busbar) and Record voltage V2.

2.5 Disconnect the test equipment and compare the results with the relative Vb safety values in NR/SMS/PartZ/Z07 - Earth Leakage Reference Values.

If the required voltage Vb is not shown, use the next available lower voltage.

2.6 Investigate any readings that are outside the required values shown in the tables in Part Z. Any investigations shall be reported to your SM(S).

END

General

Dynamic Earth Testing is broken into Un-monitored and Electronically Monitored Busbars.

Only one of the tests should be completed.

The tester should choose the type depending on the equipment to be tested.

Method for connecting test equipment is as NR/SMS/PartB/Test/051 (Busbar Earth Tests) - Section 1 for DC circuits and Section 2 for AC circuits.

UN-MONITORED BUSBARS

1. Power Worked Points

1.1 Whilst the points are moved from both N-R and R-N measure and record the maximum positive and negative drive voltage between busbar and earth.

1.2 Measure and record the voltage across each leg of the detection circuit.

1.3 Measure and record the voltage between each leg of the detection circuit and earth for each lie of the points.

1.4 Compare the results with the table in NR/SMS/PartZ/Z07 (Earth Leakage – Reference Values).

1.5 Investigate any readings that are outside the required values shown in the tables in Part Z.

1.6 This test shall be repeated following the investigation / clearance of any earths.

Any investigations shall be reported to your SM(S).

2. Level Crossing Barriers

2.1 Measure and record the maximum positive and negative drive voltage between 24v busbar and earth during a complete cycle of the crossing.

2.2 Compare the results with the table in NR/SMS/PartZ/Z07 (Earth Leakage – Reference Values).

2.3 Investigate any readings that are outside the required values shown in the tables in Part Z.

2.4 This test shall be repeated following the investigation / clearance of any earths.

Any investigations shall be reported to your SM(S).

3. Generic Dynamic Earth Test (Including AWS Electro magnets)

3.1 Liaise with the Signaller to set up the conditions by asset to be tested is energised.

3.2 Measure and record the voltage across each leg of the magnet feed circuit as the equipment changes state.

3.3 Compare the results with the table in NR/SMS/PartZ/Z07 (Earth Leakage – Reference Values).

3.4 Investigate any readings that are outside the required values shown in the tables in Part Z.

3.5 This test shall be repeated following the investigation / clearance of any earths.

Any investigations shall be reported to your SM(S).

ELECTRONICALLY MONITORED BUSBARS

4. Power Worked Points

4.1 Observe the readings displayed by the Electronic Monitoring Device whilst the points are moved from both N-R and R-N twice.

4.2 Record and investigate any alarms that are triggered.

4.3 This test shall be repeated following the investigation / clearance of any earths.

Any investigations shall be reported to your SM(S).

5. Level Crossing Barriers

5.1 Observe the readings displayed by the Electronic Monitoring Device whilst the barriers are raised and lowered twice.

5.2 Record and investigate any alarms that are triggered.

5.3 This test shall be repeated following the investigation / clearance of any earths.

Any investigations shall be reported to your SM(S).

END

Includes:	930 Type, P Style Units, Bender IR145, Bender IR425
Excludes:	All other ELD's and Bender units

GENERAL

Due to the number of different styles of Earth Leakage Detector (ELD) that are now fitted across the Network this test is broken into three parts.

The tester carrying out this task should identify the type of ELD they are testing from the list below and only carry out the tasks within that test and its Setup Appendix (if required):

- **Part A** - 930 Type and P Style Units.
- **Part B** - Bender IR145.
- **Part C** - Bender IR425.
- **Part D** – Siemens ELD.

PART A - 930 Type and P Style Units

Equipment Identification

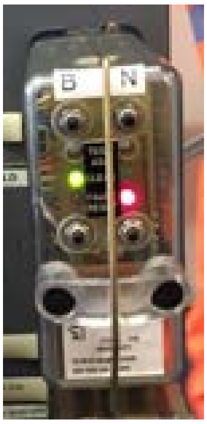


Figure 2 - 930 Style ELD

Figure 1 - P Type ELD

1. Function Test - 930 Type and P Style Units

1.1 Measure and record the busbar voltage/s on the record card.

1.2 Check and record the indications shown on the earth leakage detector.

1.3 If an earth fault is indicated, attempt to clear the indication and record the result.

Where fault persists, investigate the cause, and carry out NR/SMS/PartB/Test/051 (Earth Busbar Test).

Rectify any earth faults above the reportable limit. NR/SMS/PartZ/Z07 (Earth Leakage – Reference Values).

All faults shall be reported to your SM(S).

If the fault is unrectified your SM(S) shall be advised within 24 hours.

2. Calibration Test - 930 Type and P Style Units

2.1 Remove the ELD using the correct SMTH test plan.

2.2 Measure and record the voltage across each busbar.

2.3 Carry out NR/SMS/PartB/Test/051 (Earth Busbar Test) on each busbar.

Rectify any earth faults above the reportable limit. NR/SMS/PartZ/Z07 (Earth Leakage – Reference Values).

All faults shall be reported to your SM(S).

If the fault is unrectified your SM(S) shall be advised within 24 hours.

2.4 Re-instate ELD using the SMTH Test Plan.

2.5 Observe the ELD shows earth free indication.

2.6 Connect an electronic calibrated meter on resistance range to the inputs of the 22K ohms resistor box. Record the reading. If the reading is not within 22K ±5% then do not use and report this to your SM(S).

2.7 Connect the 22Kohms resistor (earth fault) between:

a) Earth to each monitored busbar in turn (DC circuits).

b) or Earth and one busbar (AC circuits) for a maximum of 7 seconds.

Observe the ELD correctly indicates the earth fault. Some units indicate after one second, some can take up to six seconds, if you are in doubt about the units you are testing, ask your SM(S).

2.8 Operate ELD test button and observe the ‘Earth Fault’ indication, for one leg of the supply.

2.9 Reset the ELD and repeat for the other leg of the supply.

2.10 If a DC ELD does not operate correctly, it might require adjustment (See Appendix A).

If the unit fails to operate on the test buttons, this can be due to a faulty main earth or test earth connection.

2.11 Reset to restore the ELD to service.

If the ELD is found to be defective:

a) Isolate the defective ELD safely from the operational busbar and label it as faulty.

b) Immediately carry out NR/SMS/PartB/Test/051 (Earth Busbar Test).

c) Treat circuits as not monitored by ELD until remedial action is completed.

Rectify any earth faults above the reportable limit. NR/SMS/PartZ/Z07 (Earth Leakage – Reference Values).

All faults shall be reported to your SM(S).

If the fault is unrectified your SM(S) shall be advised within 24 hours.

PART B – IR145 Bender Units

Equipment Identification

Figure 3 - IR145 Bender Unit

3. Operation

Within the IR145Y a measuring signal is generated which is connected to the system via the terminals L1/L2 and is connected to ground via the terminals /KE.

These connections are monitored continuously. If one of these connections is interrupted, this is indicated by flashing alarm LEDs and alarm relay.

4. Function Test - IR145 Bender Units

4.1 Measure and record the busbar voltage/s on the record card.

4.2 Check and record the indications shown on the earth leakage detector.

4.3 Check the green power on LED is illuminated.

4.4 Push and hold depressed the “Test / Reset” button for more than 2.5 seconds.

During a successful test both fault LEDs should illuminate while the button is depressed and extinguished when it is released.

4.5 If either of the fault LED’s fails to illuminate during the test or remains lit after the button has been released it shall be investigated as a fault.

4.6 If you are unable to eliminate the fault condition, then the following action shall be taken:

a) Isolate the defective ELD safely from the operational busbar and label it as faulty

b) Carry out NR/SMS/PartB/Test/051 (Busbar Earth Test) Immediately.

c) Advise your SM(S).

d) Treat the circuits as unmonitored by ELD until remedial action has been completed.

4.7 Reset the unit by pressing the “Test / Reset” button for less than 1 second. Observe the ELD unit for a period of 60 seconds for further alarms.

5. Calibration Test - IR145 Bender Units

5.1 Measure and record the voltage across each busbar.

5.2 Observe the unit alarm indications are clear.

5.3 Connect an electronic meter on resistance range to the inputs of the 22K ohms resistor box. Record the reading. If the reading is not within 22K ±5% then do not use and report this to your SM(S).

5.4 Connect the 22Kohms resistor (earth fault) between:

a) Earth to each monitored busbar in turn (DC circuits).

b) or Earth and one busbar (AC circuits) for a maximum of 7 seconds.

5.5 Observe the alarm Illuminate.

5.6 If none of the Fault LED's illuminate, then the following action shall be taken:

a) Remove and label the failed ELD.

b) Immediately carry out NR/SMS/PartB/Test/051 (Earth Busbar Test on each busbar).

c) Advise your SM(S).

d) Treat the circuits as unmonitored by ELD until remedial action has been completed.

5.7 Reset the unit by pressing the "Test / Reset" button for less than 1 second. Observe the ELD unit for a period of 60 seconds for further alarms.

PART C – IR425 Bender Units

Equipment Identification

Figure 4 – IR425 Bender Unit

6. Operation

The IR425 generates a pulsating measuring voltage which is superimposed on the power supply system being monitored via the terminals L1/L2 and KE/earth.

The current measured insulation resistance is shown on the display of the device.

A distinction is made between insulation faults on the AC or DC side. In the event of insulation faults on the plus or minus conductor, the corresponding +/- symbol is activated on the display.

7. Function Test – IR425 Bender Unit

7.1 Measure and record the busbar voltage/s on the record card.

7.2 Check and record the indications shown on the earth leakage detector.

7.3 Push and hold depressed the “T” button for 2.5 seconds.

The display should now indicate “TES” followed, after a short period by all three LED’s illuminating. This indicates a successfully completed test.

In the case of the unit failing this test all three LED’s flash and an error code is displayed. The meanings of these error codes are as follows:

a) E01 = PE connection fault, indicating a low-resistance connection between “E” and “KE” terminals.

b) E02 = System connection fault a low-resistance connection between “L1” and “L2” terminals.

c) E03...Exx = An Internal Device error.

7.4 Investigate and rectify all faults, if you are unable to eliminate the fault condition then the following action shall be taken:

a) Isolate the defective ELD safely from the operational busbar and label as faulty.

b) Carry out NR/SMS/PartB/Test/051 (Busbar Earth Test) immediately.

c) Advise your SM(S);

d) Treat the circuits as unmonitored by ELD until remedial action has been completed.

7.5 Reset the unit by pressing the "R" reset button for more than 1.5 sec. Observe the ELD unit for a period of 60 seconds for further alarms.

8. Calibration Test – IR425 Bender Unit

8.1 Measure and record the busbar voltage/s on the record card.

8.2 Check and record the indications shown on the earth leakage detector.

8.3 Observe the unit alarm indications are clear.

8.4 Observe the current resistance reading on the display, if the reading is smaller than 100K ohms, investigate the cause, if unable to find the cause report this to your SM(S), isolate the ELD and carry out NR/SMS/PartB/Test/051 (Earth Busbar Test).

If the current resistance reading is equal to or more than 100K ohms then proceed to the next step.

8.5 Connect an electronic calibrated meter on resistance range to the inputs of the 22K ohms resistor box. Record the reading. If the reading is not within 22K ±5% then do not use and report this to your SM(S).

8.6 Connect the 22Kohms resistor (earth fault) between:

a) Earth to each monitored busbar in turn (DC circuits).

b) or Earth and one busbar (AC circuits) for a maximum of 7 seconds.

8.7 Observe the following:

a) For monitoring supply >72v alarm 1 & alarm 2 LEDs are lit.

b) For monitoring supply <72v alarm 1 LED is lit.

Alarm 1 might not trigger if the current resistance reading displayed is showing >500K ohms on the display.

If this is the case observe the resistance reading on the display with the 22K ohm resistor connected, if the reading falls gradually to just below 22K ohms but higher than 20K ohms then record this test as ok.

Some units can have a delay setting of more than 7 seconds, in this case Alarm1 and/or Alarm 2 might not light within the seven seconds.

If this is the case, then do the test as in Step 8.5 (b) above by observing the resistance reading.

8.8 If any of the tests carried out in Step 8.5 have failed, then the following action shall be taken:

a) Isolate the defective ELD safely from the operational busbar and label it as faulty.

b) Carry out NR/SMS/PartB/Test/051 (Busbar Earth Test) Immediately.

c) Advise your SM(S).

d) Treat the circuits as unmonitored by ELD until remedial action has been completed.

8.9 Reset the unit by pressing the "R" reset button for more than 1.5 sec. Observe the ELD unit for a period of 60 seconds for further alarms.

PART D – Siemens ELD

Equipment Identification

Figure 5 – Siemens ELD

9. Function Test - Siemens ELD

Visual Settings Configuration Check

9.1 Visually confirm that LED 1 is a standard type (no DC label present) and that ELD 2 is a high-speed type (DC label on the front panel).

9.2 Visually confirm that each earth leakage detector has been configured as follows:

Earth Leakage Detector 1 - Point Detection Circuit

9.3 Sensitivity setting: confirm that the kΩ rotary control is set to 40kΩ.

If the setting looks incorrect, do not adjust the control by eye; the completed Calibration Test shall be performed.

9.4 DIP switches: confirm that top DIP switch “Reset” is in the left position and the bottom DIP switch for the output relay mode is in the right position.

Earth Leakage Detector 2 - Point Machine Power

9.5 Sensitivity setting: confirm that the kΩ rotary control is set to 50kΩ. If the setting looks incorrect, do not adjust the control by eye; the completed recalibration process shall be performed.

9.6 DIP switches: confirm that top DIP switch “Reset” is in the left position and the bottom DIP switch for the output relay mode is in the right position

Trip Operation Confirmation

The PAM auxiliary supply shall be live during this test. All resistors used in this procedure might be +/- 10% of their nominal value and the wattage =>0.25 W. Care shall be taken when connecting the probes to check that the correct terminals are used as other terminals nearby might be live.

This test requires a simulated earth fault to be connected between the monitored cables and earth. This is to confirm that the alarm activates when required.

To conduct these tests a resistor box shall be used (alternatively a series of resistors of correct value could be used).

One end of the resistor is connected to an earth terminal in the PAM using a lead terminated in a crocodile clip. The other end of the resistor is connected to a terminal on the earth device using a lead terminated with a male test probe.

Earth Leakage Detector 1: Point Detection Supply

9.7 In the case of the earth leakage detector being set to the lower level, use an 8kΩ resistor in place of the 30kΩ and an 18kΩ in place of the 68kΩ.

9.8 Disconnect links 54 and 55 to isolate the auxiliary supply.

9.9 Remove lightning suppressors 10 and 11 to disconnect the ELD from the detection circuit.

9.10 Reconnect links 54 and 55 to restore the auxiliary supply.

9.11 Using the 30kΩ resistor, connect the crocodile clip to earth. Confirm that the earth leakage detector is powered up and not showing an alarm condition.

9.12 Touch and hold the probe end of the resistor lead to the L1 terminal of the earth leakage detector. Within 5 seconds both yellow alarm LEDs should light up.

9.13 Remove the probe and reset the fault on the detector. Then touch and hold the probe end of the resistor lead to the L2 terminal of the earth leakage detector. Within 5 seconds both yellow alarm LEDs should light up.

9.14 Remove the probe, reset the fault on the detector and change the resistor to 68kΩ. Then touch and hold the probe end of the resistor lead to the L1 terminal of the earth leakage detector. After 15 seconds NEITHER yellow alarm LED should have illuminated on the ELD.

9.15 Remove the probe. Then touch and hold the probe end of the resistor lead to the L2 terminal of the earth leakage detector. After 15 seconds NEITHER yellow alarm LED should have illuminated on the ELD.

9.16 Disconnect links 54 and 55 to isolate the auxiliary supply.

9.17 Replace lightning suppressors 10 and 11.

9.18 Reconnect links 54 and 55 to restore the auxiliary supply.

<u>Earth Leakage Detector 2: Point Machine Power</u>

9.19 In the case of the earth leakage detector being set to the lower level, use an 18kΩ resistor in place of the 39kΩ and a 27kΩ in place of the 82kΩ.

9.20 Disconnect links 54 and 55 to isolate the auxiliary supply.

9.21 Remove lightning suppressors 7, 8 and 9 to disconnect the ELD from the point machine power circuit.

9.22 Remove and retain the 10kΩ ELD dummy load module from the WAGO terminal position 36A and replace with a temporary 1kΩ ELD calibration dummy load module.

9.23 Reconnect links 54 and 55 to restore the auxiliary supply.

9.24 Using the 39 kΩ resistor connect the croc clip to earth. Confirm that the earth leakage detector is powered up and not showing an alarm condition.

9.25 Touch and hold the probe end of the resistor lead to the L1 terminal of the earth leakage detector. Within 2 seconds the 'Alarm +' yellow alarm LED should light up.

9.26 Remove the probe and reset the fault on the detector. Then touch and hold the probe end of the resistor lead to the L2 terminal of the earth leakage detector. Within 2 seconds the 'Alarm -' yellow alarm LED should light up.

9.27 Remove the probe, reset the fault on the detector and change the resistor to 82kΩ. Then touch and hold the probe end of the resistor lead to the L1 terminal of the earth leakage detector. After 10 seconds neither yellow alarm LED should have illuminated on the ELD.

9.28 Remove the probe. Then touch and hold the probe end of the resistor lead to the L2 terminal of the earth leakage detector. After 10 seconds neither yellow alarm LED should have illuminated on the ELD.

9.29 Disconnect links 54 and 55 to isolate the auxiliary supply.

9.30 Remove and retain the temporary 1kΩ ELD calibration dummy load module from the WAGO terminal position 36A and replace with the 10kΩ ELD dummy load module.

9.31 Replace lightning suppressors 7, 8 and 9.

9.32 Reconnect links 54 and 55 to restore the auxiliary supply.

NOTE: *If a move is called with the 1kΩ ELD calibration dummy load module connected then it might be damaged. Confirm that it is disconnected before moving the points.*

10. Calibration Test - Siemens ELD

Calibration requires a simulated earth fault to be connected between the monitored cables and earth. This is to confirm that the alarm activates when required.

To conduct these tests a resistor box shall be used (alternatively a series of resistors of correct value could be used).

One end of the resistor is connected to an earth terminal in the PAM using a lead terminated in a croc clip. The other end of the resistor is connected to a terminal on the earth device using a lead terminated with a male test probe.

<u>Earth Leakage Detector 1: Point Detection Supply</u>

10.1 In the case of the earth leakage detector being set to the lower level, use an 8kΩ resistor in place of the 30kΩ, an 11kΩ in place of the 40kΩ and an 18kΩ in place of the 68kΩ.

10.2 Disconnect links 54 and 55 to isolate the auxiliary supply.

10.3 Remove lightning suppressors 10 and 11 to disconnect the ELD from the detection circuit.

10.4 Reconnect links 54 and 55 to restore the auxiliary supply.

10.5 Check that the small switches on the front of the ELD are set to top switch left and bottom switch right. Turn the ELD calibration knob to approximately 30kΩ.

10.6 Using the 40kΩ resistor, connect the crocodile clip to earth. Confirm that the earth leakage detector is powered up and not showing an alarm condition. Touch and hold the probe end of the resistor lead to the L1 terminal of the earth leakage detector.

10.7 Turn the ELD calibration knob very slowly clockwise (upwards) until the ELD unit just produces a fault. Note that the response time of the ELD unit is 5 s, so it is necessary to move the control a little at a time, waiting at least 5 seconds before moving it again.

10.8 Remove the probe, reset the fault on the detector and change the resistor to 30 kΩ. Then touch and hold the probe end of the resistor lead to the L1 terminal of the earth leakage detector. Within 5 seconds both yellow alarm LEDs should illuminate.

10.9 Remove the probe and reset the fault on the ELD. Then touch and hold the probe end of the resistor lead to the L2 terminal of the earth leakage detector. Within 5 seconds both yellow alarm LEDs should Illuminate.

10.10 Remove the probe, reset the fault on the detector and change the resistor to 68 kΩ. Then touch and hold the probe end of the resistor lead to the L1 terminal of the earth leakage detector. After 15 seconds neither yellow alarm LED should have illuminated on the ELD.

10.11 Remove the probe. Then touch and hold the probe end of the resistor lead to the L2 terminal of the earth leakage detector. After 15 seconds neither yellow alarm LED should have illuminated on the ELD.

10.12 Check the setting of the calibration control on the ELD graduated scale. If it appears to be more than 10kΩ from the setting of 40kΩ desired, then suspect there is a problem with the detector or wiring. Investigate and correct as necessary.

10.13 Disconnect links 54 and 55 to isolate the auxiliary supply.

10.14 Replace lightning suppressors 10 and 11.

10.15 Reconnect links 54 and 55 to restore the auxiliary supply.

<u>Earth Leakage Detector 2: Point Machine Power</u>

In the case of the earth leakage detector being set to the lower level, use an 18kΩ resistor in place of the 39kΩ, a 22kΩ in place of the 50kΩ and a27 kΩ in place of the 82kΩ

10.16 Disconnect links 54 and 55 to isolate the auxiliary supply.

10.17 Remove lightning suppressors 7, 8 and 9 to disconnect the ELD from the point machine power circuit.

10.18 Remove and retain 10kΩ ELD dummy load module from the WAGO terminal position 36A and replace with a temporary 1kΩ ELD calibration dummy load module.

10.19 Reconnect links 54 and 55 to restore the auxiliary supply.

10.20 Check that the small switches on the front of the ELD are set to top switch left and bottom switch right. Turn the ELD calibration knob to approximately 40kΩ.

10.21 Using the 50kΩ resistor, connect the crocodile clip to earth. Confirm that the earth leakage detector is powered up and not showing an alarm condition. Touch and hold the probe end of the resistor lead to the L1 terminal of the earth leakage detector.

10.22 Turn the ELD calibration knob very slowly clockwise (upwards) until the ELD unit just produces a fault.

NOTE: *The response time of the ELD unit is 2 s, so it is necessary to move the control a little at a time, waiting at least 2 seconds before moving it again.*

10.23 Remove the probe, reset the fault on the detector and change the resistor to 39kΩ. Then touch and hold the probe end of the resistor lead to the L1 terminal of the earth leakage detector. Within 2 seconds the "Alarm +" yellow alarm LED should illuminate.

10.24 Remove the probe and reset the fault on the ELD. Then touch and hold the probe end of the resistor lead to the L2 terminal of the earth leakage detector. Within 2 seconds the "Alarm -" yellow alarm LED should illuminate.

10.25 Remove the probe, reset the fault on the detector and change the resistor to 82kΩ. Then touch and hold the probe end of the resistor lead to the L1 terminal of the earth leakage detector. After 10 seconds neither yellow alarm LED should have illuminated on the ELD.

10.26 Remove the probe. Then touch and hold the probe end of the resistor lead to the L2 terminal of the earth leakage detector. After 10 seconds neither yellow alarm LED should have illuminated on the ELD.

10.27 Check the setting of the calibration control on the ELD graduated scale. If it appears to be more than 10kΩ from the desired setting of 50kΩ, desired then suspect there is a problem with the detector or wiring. Investigate and correct as necessary.

10.28 Disconnect links 54 and 55 to isolate the auxiliary supply.

10.29 Remove and retain the temporary 1kΩ ELD calibration dummy load module from the WAGO terminal position 36A and replace with a 10kΩ ELD dummy load module.

10.30 Replace lightning suppressors 7, 8 and 9.

10.31 Reconnect links 54 and 55 to restore the auxiliary supply.

NOTE: *If a move is called with the 1KΩ ELD calibration dummy load module connected then it might be damaged. Confirm that it is disconnected before moving the points.*

APPENDIX A - Calibration and Adjustment - 930 Type and P Style Units

This test is only applicable to Type DC ELK (S)1 and DC ELK(S)2 for DC supplies (pin code 239).

This test shall only be undertaken at times when train movements have stopped, as the set up requires an earth fault to be simulated.

If automatic reset straps are fitted (C6 C7 C8), these shall be removed for the duration of the adjustment test and reconnected on completion.

1. Check the signalling supply is earth free before any adjustments are made by carrying out NR/SMS/PartB/Test/051 (Busbar Earth Test).

   Rectify any earth faults above the reportable limit. NR/SMS/PartZ/Z07 (Earth Leakage – Reference Values).

   All faults shall be reported to your SM(S).

   If the fault is unrectified your SM(S) shall be advised within 24 hours.

   The calibration shall not be carried out on a supply with an earth, as the adjustment made would mask the presence of the earth.

2. For the 50V DC supply, connect a 50KΩ resistor of at least 0.25W, between B50 and main earth.

   These connections shall be made at positions A3 and B3.

3. For the 120V DC supply, connect a 33KΩ resistor of at least 2W, between B120 and main earth.

   These connections shall be made at positions A1 and B1.

4. Whilst pressing the (B) test button, carefully set the left hand “adjust” screw, so that the point is reached at which the fault indication is only just given.

   For the 50V DC supply, connect the resistor between C3 and B3.

   For the 130V DC supply, connect the resistor between C1 and B1.

5. Whilst pressing the (N) test button, carefully set the left hand “adjust” screw, so that the point is reached at which the fault indication is only just given.

6. Remove resistor.

7. Reset to restore the ELD to service.

APPENDIX B - Unit Controls, Indications and Connections- IR145

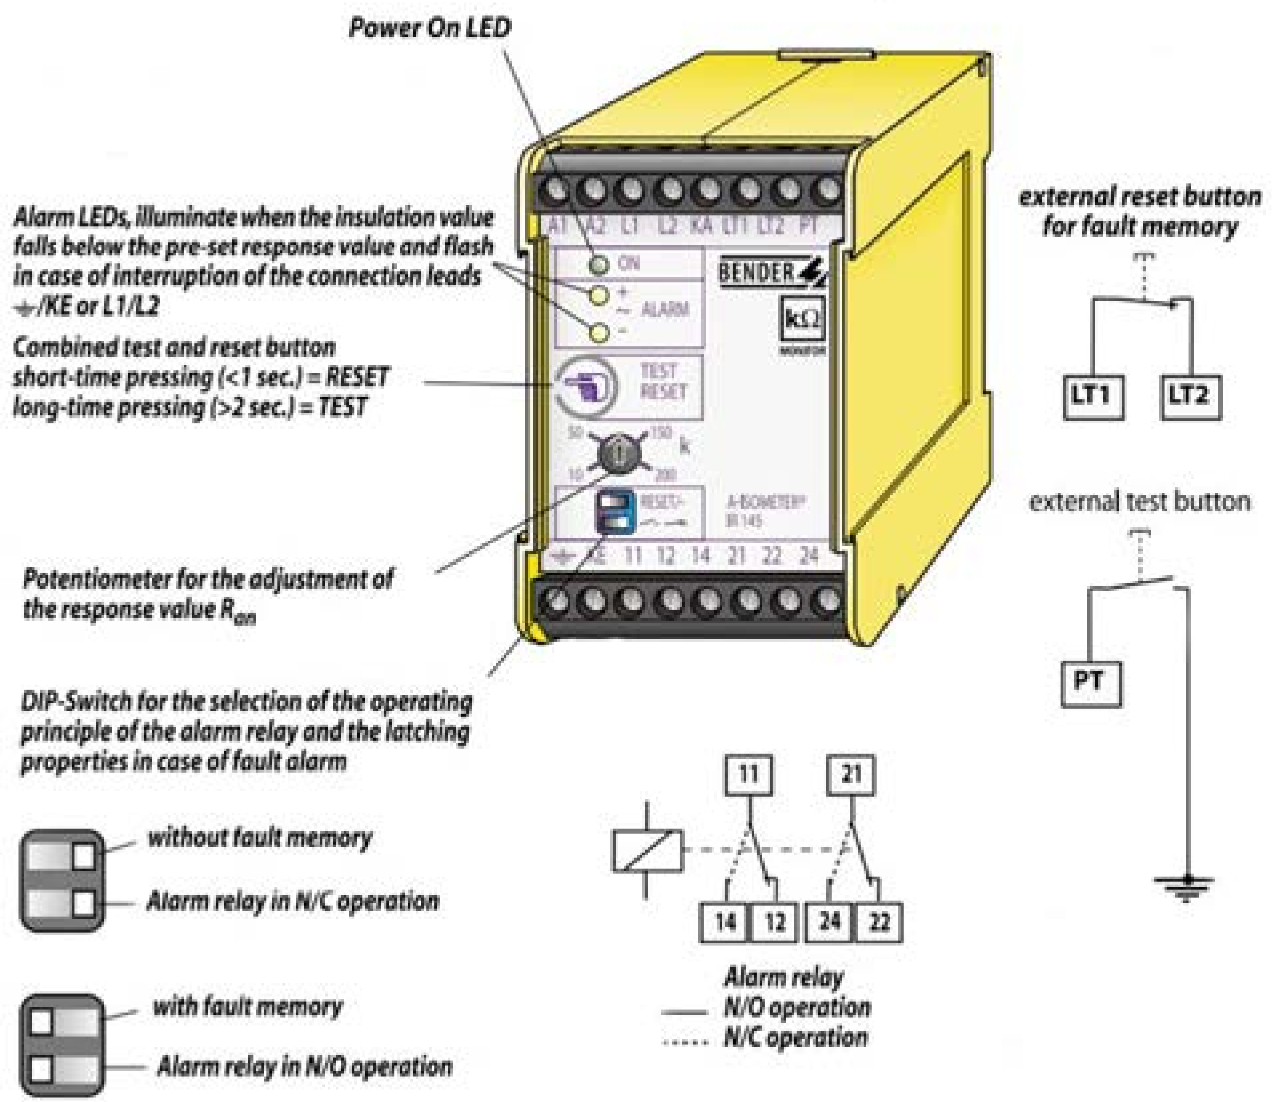

Figure 6 - IR145 Layout

1. Activating / Deactivating the Fault Memory

   The fault memory is Activated / Deactivated using the top toggle switch on the front of the unit as indicated in Figure 5.

2. Alarm Relay

   This option is used to change the behaviour of the contacts between normally closed (N/C) (non-failsafe) mode and normally open (N/O) (failsafe) mode.

   The contact operation is controlled by using the bottom toggle switch on the front of the unit as indicated in Figure 5.

APPENDIX C - Unit Controls and Indications IR425 Bender Units

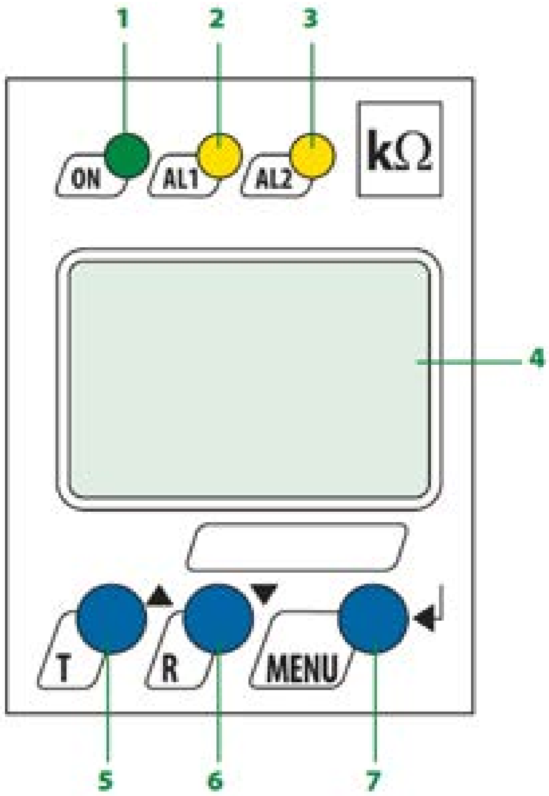

Figure 7 –IR425 Bender Units

1. LED power “ON”, (flashes in case of interruption of the connecting leads E/KE or L1/L2).

2. Alarm LED “AL1”, lights when the value falls below the set response value Alarm 1 and flashes in case of interruption of the connecting leads E/KE or L1/L2.

3. Alarm LED “AL2”, lights when the value falls below the set response value Alarm 2 and flashes in case of interruption of the connecting leads E/KE or L1/L2.

4. LC display.

5. Test button “T”: to call up the self-test.

   Arrow up button: parameter change, to move up in the menu.

6. Reset button “R”: to delete stored insulation fault alarms.

   Arrow down button: parameter change, to move down in the menu.

7. Menu button “MENU”: to call up the menu system. Enter button: Confirms parameter changes.

APPENDIX D - Setting up the Parameters – Bender Unit IR425-D4M1C

WARNING Default Settings

After connecting the unit to both the power supply to be monitored and the supply voltage for the first time, the following default setting are applied:

Response value (R2)	>72V = 23 kΩ ≤72V = 10 kΩ
Operating Mode R2	N/O operation
R2 Fault memory	Deactivated
M1C current output	0-20mA
Starting delay	t=0s
Response delay	t_{on}=0s
Password	1, disabled

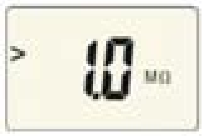
Table 1 – Default Setting

If the unit is reset the default settings automatically become active again.

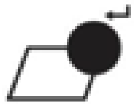
The default response values are not acceptable on Network Rail Infrastructure and shall be adjusted to meet the Network Rail Parameters, using the process explained in this Appendix.

<u>Parameter R2</u>

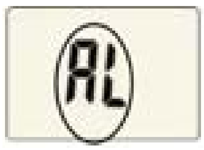
1. From the Monitoring Screen.



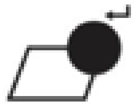
2. To enter the Menu Mode, press the MENU/Enter button on the front display for more than 1.5 seconds.



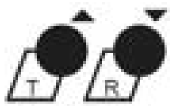
3. A flashing “AL” symbol appears on the screen.



4. This is the Alarm Mode screen. Press the MENU/Enter button for less than 1.5 seconds.



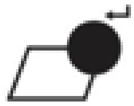
5. The parameter R1 flashes.



6. Press the R / Down key to select the parameter R2.

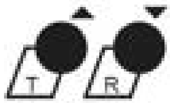
7. The parameter R2 flashes.

8. Confirm this by pressing the MENU/Enter button for less than 1.5 seconds.

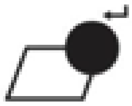


9. The current R2 value in kΩ then flashes.

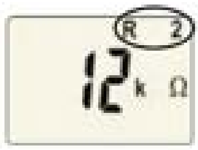
10. Use the T / Up or R / Down key to adjust the parameter value to the require figure.



11. Press the MENU/Enter button for more than 1.5 seconds.



12. The parameter R 2 flashes.



13. The new parameter is now set, and you can exit the menu by:

    a) pressing the Enter key for more than 1.5 seconds to reach the next higher level.

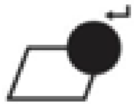
    b) or selecting the menu item ESC and confirming with Enter to reach the next higher level.

14. This returns you to the Monitoring Screen.

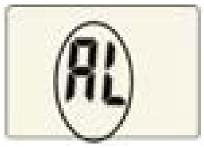
Current Output Parameter (M1C)

15. From the Monitoring Screen.

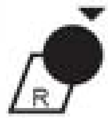
16. To enter the Menu Mode, press the MENU/Enter button on the front display for more than 1.5 seconds.



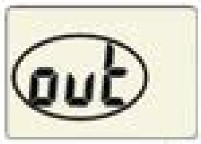
17. A flashing “AL” symbol appears on the screen.



18. Press the R / Down button once.



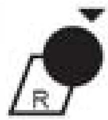
19. The word “out” appears and flashes.



20. To enter the current output, press the MENU/Enter once for less than 1.5 seconds.

    On or OFF appears (as appendix C section7).

    Press the R / Down button twice.

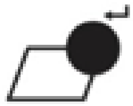


21. The display “0.20mA” or “4.20mA” appears steady with a flashing **I**.

22. Press the MENU/Enter once for less than 1.5 seconds.

23. Select the required range (4.20mA). The display continues to flash during this process.

24. Press the MENU/Enter once for more than 1.5 seconds.



25. The new parameter is now set, and you can exit the menu by:

    a) pressing the Enter key for more than 1.5 seconds to reach the next higher level.

    b) or selecting the menu item ESC and confirming with Enter to reach the next higher level.

26. This returns you to the Monitoring Screen.

APPENDIX E - Setting up the Parameters – Bender Unit IR425 (Not D4M1C type)

WARNING Default Settings

After connecting the unit to both the power supply to be monitored and the supply voltage for the first time, the response values Ran1/Ran2 (Alarm 1/2) are automatically set to the following:

For voltages greater than 72 V

- Response value 1 = 46 kΩ
- Response value 2 = 23 kΩ

For voltages less than or equal to 72 V

- Response value 1 = 20 kΩ
- Response value 2 = 10 kΩ

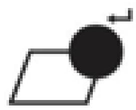
If the unit is reset the default settings automatically become active again.

These values are not acceptable on Network Rail Infrastructure and shall be adjusted meet the Network Rail Parameters, using the process explained in this Appendix.

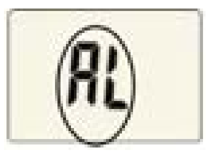
<u>Parameter R2</u>

1. From the Monitoring Screen.

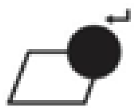
2. To enter the Menu Mode, press the MENU/Enter button on the front display for more than 1.5 seconds,



3. A flashing “AL” symbol appears on the screen.

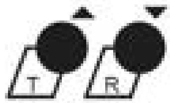


4. This is the Alarm Mode screen. Press the MENU/Enter button for less than 1.5 seconds.



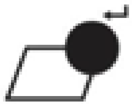
5. The parameter R1 flashes.

6. Press the R / Down key to select the parameter R2.

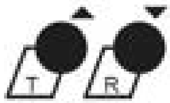


7. The parameter R2 flashes.

8. Confirm this by pressing the MENU/Enter button for less than 1.5 seconds.

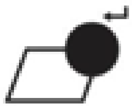


9. The current R2 value in kΩ flashes.



10. Use the T / Up or R / Down key to adjust the parameter value to the require figure shown in [NR/SMS/PartZ/Z07]() (Earth Leakage – Reference Values).

11. Press the MENU/Enter button for more than 1.5 seconds.



12. R 2 flashes.

13. The new parameter is now set, and you can exit the menu by:

    a) pressing the Enter key for more than 1.5 seconds to reach the next higher level.

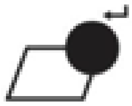
    b) or selecting the menu item ESC and confirming with Enter to reach the next higher level.

14. This returns you to the Monitoring Screen.

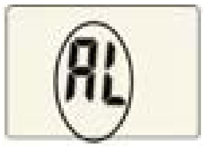
Parameter R1

15. From the Monitoring Screen.

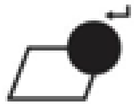
16. To enter the Menu Mode, press the MENU/Enter button on the front display for more than 1.5 seconds.



17. A flashing “AL” symbol appears on the screen.

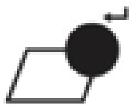


18. This is the Alarm Mode screen. Press the MENU/Enter button for less than 1.5 seconds.



19. The parameter R1 flashes.

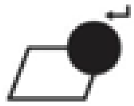
20. Confirm this is the parameter you want to adjust by pressing the MENU/Enter button for less than 1.5 seconds.



21. The current R1 value in kΩ then flashes.

22. Use the T / Up or R / Down key to adjust the parameter value to the require figure shown in NR/SMS/PartZ/Z07 (Earth Leakage – Reference Values).

23. Press the MENU/Enter button for more than 1.5 seconds.



24. R 1 flashes.

25. The new parameter is now set, and you can exit the menu by:

    a) pressing the Enter key for more than 1.5 seconds to reach the next higher level.

    b) or selecting the menu item ESC and confirming with Enter to reach the next higher level.

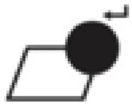
26. This returns you to the Monitoring Screen.

APPENDIX F - Activating / Deactivating the Fault Memory- All IR425 Bender Units

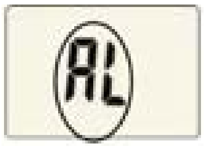
Changing this setting to “ON” causes the IR420-D4 to latch in the event of an alarm and require a manual reset if the alarm clears. Changing this setting to “OFF” causes the IR425 to automatically reset if the alarm clears. For location cases utilising the Atkins Signalling Method the fault memory should be set to “OFF”.

1. From the Monitoring Screen.

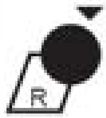
2. To enter the Menu Mode, press the MENU/Enter button on the front display for more than 1.5 seconds.



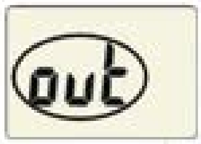
3. A flashing AL symbol appears on the screen.



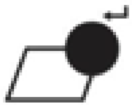
4. Press the R / Down button once.



5. The word “out” appears and flashes.

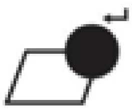


6. To enter the Latching Mode (Fault Memory), press the MENU/Enter once for less than 1.5 seconds.



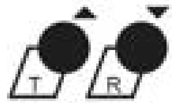
7. The word “on” or “off” appears with a flashing “M” under it. This indicates you are in the Latching Mode.

8. Press the MENU/Enter once for less than 1.5 seconds.



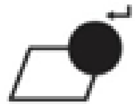
9. The word “on” or “off” appears and starts to flash.

10. The T / Up or the R / Down buttons can now be used to move the Latching Mode (Fault Memory) to the required position. The display continues to flash during this process.



11. Once the required position is set.

12. Press the MENU/Enter once for more than 1.5 seconds.

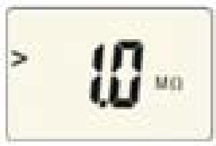


13. The new parameter is now set, and you can exit the menu by:

   a) pressing the Enter key for more than 1.5 seconds to reach the next higher level;

   b) or selecting the menu item ESC and confirming with Enter to reach the next higher level.

14. This returns you to the Monitoring Screen.



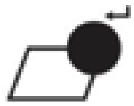
APPENDIX G - Contact operation – All Bender IR425 Units

Use this option to change the behaviour of the contacts between normally deenergized (non-failsafe) mode and normally energized (failsafe) mode.

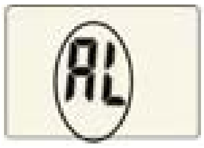
Note that the IR425 labels normally deenergized operation as “N/O” and normally energized operation as “N/C”. For location cases utilising the Atkins Signalling Method the R2 contact output should be normally energised “N/C”.

1. From the Monitoring Screen.

2. To enter the Menu Mode, press the MENU/Enter button on the front display for more than 1.5 seconds.

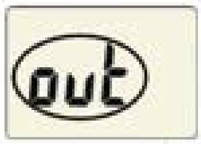


3. A flashing AL symbol appears on the screen.

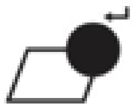


4. Press the R / Down button once.

5. The word “out” appears and flashes.



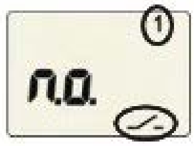
6. To enter the Latching Mode (Fault Memory), press the MENU/Enter once for less than 1.5 seconds.



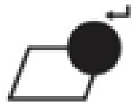
7. The word “on” or “off” appears with a flashing “M” under it. This indicates you are in the Latching Mode.

8. Press the R / Down button once.

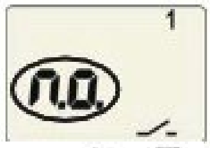
9. This screen shows the current position of the contacts “n.o.” (Normally Open) with a flashing open contact graphic and the contact number.

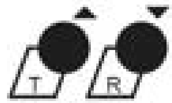


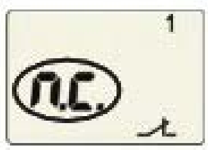
10. To adjust the contact operation, press the MENU/Enter once for less than 1.5 seconds.



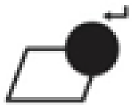
11. With the “n.o.” now flashing the T / Up or the R / Down buttons can be used to set the contacts to the “nc” (Normally Closed) position. The display continues to flash during this process.







12. Press the MENU/Enter once for more than 1.5 seconds.



13. The new parameter is now set, and you can exit the menu by:

    a) pressing the Enter key for more than 1.5 seconds to reach the next higher level;

    b) or selecting the menu item ESC and confirming with Enter to reach the next higher level.

14. This returns you to the Monitoring Screen.

END

Includes:	Existing Cables and when bringing spare cores back into use. Cables being replaced under Signal Maintenance Testing Handbook CA02 and CA07
Excludes:	New cables shall be tested using Signalling Works Test Handbook TS3-01

General

Insulation testing shall be undertaken where cable insulation values cannot be checked by earth busbar testing or by reference to an ELD indication.

It is more onerous than busbar testing as it requires the isolation of the whole cable or specific cores, before testing.

Insulation testing is usually restricted to the following cables:

a) Earth balanced / return circuits:e.g. telephones, block circuits.

b) Power cables: With a nominal voltage greater than 110V AC or 120V DC.

Cables that have a voltage greater than 175V shall be disconnected and isolated in accordance with authorised electrical safety procedures.

c) Defective cables: In connection with NR/SMTH.

A 1000V insulation tester (e.g. Megger) shall be used to test power cables.

A minimum of a 250V insulation tester shall be used to test lineside cables. For telecom cables carrying signalling circuits, reference shall be made to NR/L2/TEL/30070.

Testing should be avoided during dry or frosty weather.

Section 1, 2, and 3 are for all cables except those carrying vital FDM systems which are covered in sections 4 & 5.

If you are in any doubt about the functionality of the cable you are testing, ask your SM(S).

See NR/SMS/PartZ/Z05 (Cable Reference Values) for typical cable values.

Previous results on the NR/SMS record card might give you an indication of the state of the cable insulation (see also NR/SMS/Part/R – Maintenance Record Cards).

Check the record card for any trends. If the previous results are in the 'good' range and you now find readings are in the 'acceptable' or 'defective' range, then its most likely the insulation has been damaged.

Includes:	All cables carrying signalling circuits and non-vital FDM circuits
Excludes:	Cables carrying vital FDM circuits

1. Maintenance Test (Signalling circuits and non-vital FDM circuits only)

1.1 Carry out a continuity test between the earth terminal to be used during this test and earth.

1.2 For a test to be valid, the number of spare cores that need to be tested in each cable is as follows:

a) Less than10 cores: 2 spares.

b) 10-21 cores: 3 spares.

c) Greater than 21cores: 4 spares.

If inadequate spare cores are available, then working conductors shall be disconnected to make up the difference.

1.3 Isolate the cable cores by slipping links at both ends but leave the conductors connected to the terminals.

1.4 Measure the resistance between conductors connected together and earth.

1.5 Measure the core-to-core resistance.

If any results are less than 1M ohm a Full Insulation Test shall be carried out.

1.6 Record the test results on the record card. Actions detailed in Table 1 shall be taken in line with the obtained results:

Obtained Values	**Actions**
Greater than 10M ohms	This indicates that the insulation is in **Good Condition** and no further action is required.
Between 1M ohm and 10M ohms	This indicates that the insulation is in **Acceptable Condition** and no immediate action is required.
Below 1M ohm	This indicates that the insulation has degraded or is **Defective**. It shall be reported to your SM(S) immediately and shall not be left in service without the relevant authority (see NR/SMS/PartZ/Z05 (Cable Reference Values).

Table 1 – Maintenance Test Actions Table

1.7 Under the direction of the SM(S) divert circuits onto good / acceptable spare cores as shown in NR/SMTH/Part01/Module/12 (The Diversion of a Circuit/Relay Contact or Emergency Equipment Relocation).

Append the local site diagrams with details of the diversions and the Technician's name, date and signature of when the diversion was applied.

2. Full Insulation Test (Signalling circuits and non-vital FDM circuits only)

This test shall be undertaken if measurements taken in the maintenance test are less than 1Mohm.

2.1 Confirm that the earth terminal to be used during this test is connected to earth.

2.2 Test all cores in the cable.

2.3 Isolate the cable cores by slipping links at both ends but leave the conductors connected to the terminals.

2.4 Measure the resistance between conductors connected together and earth.

2.5 Measure the core-to-core resistance.

2.6 Record the test results on the record card. The actions detailed in Table 2 shall be taken in line with the obtained results:

Obtained Values	Actions
Greater than 10M ohms	This indicates that the insulation is in **Good Condition** and no further action is required
Between 1Mohm and 10M ohms	This indicates that the insulation is in **Acceptable Condition** and no immediate action is required.
Below 1M ohm	This indicates that the insulation has degraded or is **Defective**. It shall be reported to your SM(S) immediately and shall not be left in service without the relevant authority (see NR/SMS/PartZ/Z05 (Cable Reference Values).

Table 2 – Full Test Actions Table

2.7 Under the direction of the SM(S) divert circuits onto good/acceptable spare cores as shown in NR/SMTH/Part01/Module/12 (The Diversion of a Circuit/Relay Contact or Emergency Equipment Relocation).

Append the local site diagrams with details of the diversions and the Technician's name, date and signature of when the diversion was applied.

3. Cables Carrying Vital Reed FDM Circuits

Includes:	Cables carrying vital FDM circuits.
Excludes:	Cables carrying vital or non-vital FDM circuits on routes Running Parallel to FS2600 Track Circuits or on Routes Carrying Class 92 or Class 373 Trains (See section 4).

There are three ways of testing these cables (Table 3):

Method	**Details**
A	Reed non-intrusive earth leakage adaptor & digital multi-meter
B	Reed earth leakage tester
C	As detailed in section1

Table 3 – Testing Methods

Methods A and B are preferred as they test all the components connected to the cable as well as the cable itself.

It also has the advantage of not having to take the cable out of service during the tests.

The readings for both methods A&B should be taken on the line amplifier and the line-isolating transformer for each individual circuit.

3.1 Connect the adaptor/tester (Appendix A). Test the cable and record the results on the record card. Table 4 details actions that shall be taken on results obtained for existing cables:

Method	**Acceptable Reading**	**Report to SSM**	**Treat as Defective**
A&C	3M Ω & above	Between 1M Ω & 3M Ω	Less Than 1M Ω
B	3M Ω or above	Between 1.5M Ω & 2.9M Ω	1.5M Ω or Less

Table 4 – Actions One

4. Reed FDM Cables Carrying Vital or non-Vital Circuits Running Parallel to FS2600 Track Circuits or on Routes Carrying Class 92 or Class 373 Trains

Includes:	Cables carrying vital or non-vital FDM circuits on routes Running Parallel to FS2600 Track Circuits or on Routes Carrying Class 92 or Class 373 Trains only
Excludes:	Any other cables

4.1 Connect the adaptor/tester (Appendix A). Test the cable and record the results. Table 5 details actions that shall be taken on results obtained for existing cables:

Method	Acceptable Reading	Report to SM(S)	Treat as Defective
A&C	6M Ω & above	Between 1M Ω & 6M Ω	Less Than 1M Ω
B	3M Ω or above	Between 0.7M Ω & 2.9M Ω	0.7M Ω or Less

Table 5 – Actions Two

APPENDIX A - Testing Methods

Method A - Testing using the Reed Non-Intrusive Earth Leakage Adaptor and digital multi-meter

1. Confirm that the earth terminal to be used during this test is connected to earth.

2. Select DC volts on the meter and connect it to the adapter. Connect the red and green leads together and check the meter reading. If less than 9V, replace the batteries.

3. Connect the green lead to the test earth and the red lead to the circuit under test. Note the meter reading as V1.

4. Connect the red lead at the adaptor end to the terminals on the adaptor in turn in the following order (Table 6):

Order	Terminal	Reference Resistance
1st	White	1M Ω
2nd	Brown	3M Ω
3rd	Yellow	6M Ω
4th	Green	10M Ω
5th	Blue	15M Ω

Table 6 – Testing Order

The meter reading from each terminal should be noted as V2. This should reduce as the resistance value increases.

5. When V2 is lower than V1 the cable resistance to earth is lower than the reference resistance for that terminal.

Line Resistance

This can be worked out using the Reed Non-Intrusive Earth Leakage Adaptor and digital multi-meter. The method is as follows:

6. Measure the voltage across resistor R15 with the red lead strapped to the green lead. This is V1.

7. Measure the voltage across resistor R15 with the red lead connected to the cable under test and the green lead connected to earth. This is V2.

8. The resistance value (RC) can now be worked out from the application of the following formula: RC = 5 x 106 [V1/V2 – 1]. The result is shown in Ohms.

Method B - Testing using the Reed Earth Leakage Tester Values

9. Confirm that the earth terminal to be used during this test is connected to earth.

10. Connect the tester between the test earth and the circuit under test. Operate the tester and note the value on the scale. Table 7 gives the equivalent resistance to earth for the scale on the meter (Figure 1).

Meter Reading	Earth %	Equivalent ohms to Earth
Red	100%	0 Ω
9	90%	55.5k Ω
8	80%	125k Ω
7	70%	214k Ω
6	60%	333k Ω
5	50%	500k Ω
4	40%	700k Ω
3	30%	1.2M Ω
2	20%	2M Ω
1	10%	4.5M Ω
0.5	5%	9.5M Ω

Table 7 - Resistance to earth for the scale

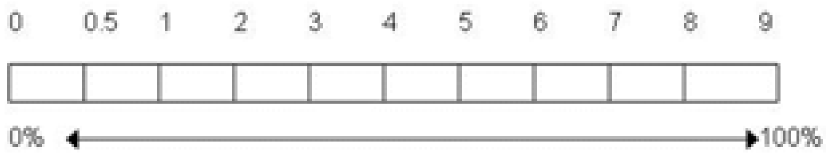


Figure 1 - Meter Scale

END

General

NR/SMS/PartC/EL00 (Secondary Cell Test) details the risks associated with testing secondary cells.

Liaise with the Signaller before turning any battery chargers off as power/equipment failure indications can be given.

1. Lead Acid / Alkaline Secondary Cells (Unsealed)

1.1 Switch the battery charger off and measure each individual cell voltage.

Allow a few minutes for the cell voltages to stabilize before taking the readings.

Cell Type	Nominal Voltage	Minimum Voltage
Lead Acid	2.2V	2V
Alkaline	1.1V	1V

Table 1 – Cell Voltages

1.2 Record the lowest reading on the record card and arrange for cells below the minimum to be replaced.

Alkaline cells usually come in banks of 3 or 5 cells (except single TC feeds). It is advisable to replace the whole bank if one is found defective.

1.3 Measure and record the full battery voltage.

1.4 Connect the voltmeter across one cell. Switch the battery charger on.

The cell voltage should rise slightly above the nominal voltage.

This indicates that the charger is working.

The nominal voltage times the number of cells.

2. Cyclon Cells (including Modular Cyclon Cells used on Point Installations)

Figure 1 - Types of Cyclon Cells

These cells are 'sealed for life' therefore topping up is not required.

2.1 With battery charger switched on, measure the full battery voltage (2.35 times the number of cells). Record the result.

2.2 Switch the battery charger off. Measure the battery voltage. Check the battery voltage does not significantly deteriorate under load. Record the results.

An ideal time for the batteries to be on load is 30 minutes, although this might not be possible in all circumstances.

2.3 Switch the battery charger on. Check that the battery voltage rises.

3. ALCAD Vantage Cells

3.1 Measure the battery voltage.

3.2 Measure the voltage of each cell, then add the highest and lowest readings together and divide the result by the total number of cells. Record the answer on the record card.

The preferable value is 1.42 to 1.43V per cell with an absolute maximum of 1.43V per cell.

Inform your SM(S) if the value is greater than 1.43V.

Appendix B lists nominal/maximum voltages for batteries. Allow the battery to stabilise if adjusted.

3.3 Switch the battery charger off and measure the battery voltage again.

Check the battery voltage does not significantly deteriorate under load.

An ideal time for the batteries to be on load is 30 minutes, although this might not be possible in all circumstances.

3.4 Record the time "on load" on the record card.

3.5 Check electrolyte levels and note the following:

- Any cells where the level that has moved significantly down from maximum towards minimum top up to the maximum line (Appendix A).

- Any cells that are below minimum but above warning level, and by how much – reported to your SM(S).

- Any cells below the warning level – report as corrective maintenance.

3.6 Measure the battery voltage after 30 minutes and compare with previous readings.

3.7 Switch the charger back on.

4. Power Box (PB) (Modular) Cells

These are 'sealed for life' cells, therefore no topping up is required.

If this test is being carried out as part of testing a replaced battery pack, it should be carried out after allowing the battery to build up its charge.

4.1 With battery charger switched on, Measure the full battery voltage on the Battery Pack between monitoring points Red 1 and Black 5.

Record the result on the record card.

4.2 Switch the battery charger off. Measure the battery voltage on the Battery Pack between monitoring points Red 1 and Black 5.

4.3 Check the battery voltage does not significantly deteriorate under load.

4.4 Record the time "on load" on the record card.

An ideal time for the batteries to be on load is 30 minutes, although this might not be possible in all circumstances

4.5 Switch the battery charger on and check that the battery voltage rises.
Redundant Power Supplies Check

4.6 Switch one of the battery strings OFF. Check that the only indication change is that the associated Battery Charger module's 24V LED changes from green to red.

4.7 Switch the battery string ON and check the associated battery charger module's 24V LED changes back to Green.

4.8 Repeat above process for the other battery string.

APPENDIX A - ALCAD Vantage Cells topping up procedure

Caution: These cells are pressurised

a) Slowly remove pressure vent cap to release pressure Do not place filler neck into cell.

b) Position over vent cap opening and inject water, observing level on external fill lines.

c) Check the vent seal is intact and not damaged before refitting vent cap. Tighten the cap until a positive stop is felt.

d) If the vent seal is not in good condition, report to your SM(S), noting whether the cap is bayonet or thread fitting.

After topping up cells, the fluid level can go up or down as the cell pressurises.

APPENDIX B - Battery Voltages for Vantage Cells

No. of Cells in Battery	Nominal Voltage	Maximum Voltage
1	1.42V	1.43V
2	2.84V	2.86V
3	4.26V	4.29V
5	7.1V	7.15V
10	14.2V	14.3V
15	21.3V	21.45V
20 #1	28.4V	28.6V
25	35.5V	35.75V
30	42.6V	42.9V
35	49.7V	50.05V
40 #2	56.8V	57.2V
45	63.9V	64.35V

No. of Cells in Battery	Nominal Voltage	Maximum Voltage
50	71V	71.5V
55	71.8V	78.65V
60	85.2V	85.8V
65	92.3V	92.95V
70	99.4V	100.1V
75	106.5V	107.25V
80	113.6V	114.4V
85 #3	120V	121.55V
90	127.8V	128.7V
95	134.9V	135.85V
100	142V	143V

#1: 24V Battery.
#2: 50V Battery.
#3: 110V Battery.

END

General

The Avel-Lindberg User Handbook contains information on settings and fault finding.

Inverters can be connected in following modes:

a) Hot standby (inverter running but not on load).

b) Cold standby (inverter not running).

c) Running permanently on load.

The 'hot' standby mode is the preferred method of connection.

Inverter systems can be a single unit only or two units acting as 'master' and 'slave'.

Due to the 'rectified DC' output from some battery chargers, it is advisable not to run the inverters from the output of a charger only as this can lead to damage of the inverter's electronics.

Switching between inverter modes (Main, Standby, Generator) can cause certain circuits (stick, indication etc) to drop and not re-pick. Always liaise with the Signaller and check all circuits are normalised on completion of testing.

All the test results shall be recorded on the record card.

1. Battery Charger

Some cells require a constant voltage charger. NR/SMS/PartC/EL00 (Electrical Equipment - General) gives you more details on these. If in doubt, ask your SM(S).

1.1 Disconnect the battery charger for 5 minutes and then test the batteries - carry out NR/SMS/PartB/Test/055 (Secondary Cell Test).

1.2 Reconnect the battery charger and (if applicable):

Measure the trickle charge current.

The charging rate is controlled electronically and is not adjustable.

1.3 Remove the BX110 and B110 fuses in turn and check that the 'Charger Supply Failed' lamp illuminates after about 10 seconds.

1.4 Replace the fuses and (if applicable) re-check the trickle charge current.

2. Automatic Switching Cabinet (Hot & Cold Standby Modes Only)

2.1 Check that all cut outs on the inverters are 'IN'.

The cut-out switches should be in the left-hand position.

Inverters on cold standby are prone to tripping when an inductive load is switched in.

If an inverter has tripped, you should also look for:

a) A low dc supply voltage, or

b) More than 10% AC ripple.

If the system is master and slave, the slave unit shall be re-set first followed by the master unit.

2.2 Check the indications on the switching cabinet.

The indications provided vary between installations. Any indicated faults shall be dealt with as corrective maintenance.

2.3 With the co-operation of the Signaller, test the standby supply.

Switch off the main power supply at its source. The inverter(s) should switch in after about 250ms. This delay can cause most relays to de-energise.

2.4 Check that a power failure is indicated on the switching cabinet and in the signal box.

2.5 Measure the following power supply values:

a) Input DC volts to the inverter switching cabinet (B110 bus-bar).

b) Output AC volts to equipment.

c) BX110 bus-bar voltage.

2.6 Check that the inverter can maintain the load without any system failures for a period representing 50% of the time that it is expected to cover. After this period, repeat step 2.5.

2.7 Test the load capability of the inverter.

Where a common 110V inverter / point battery exists, operate a double ended set of points both ways for three operations.

2.8 Restore the power supply and check that:

a) The inverters switch off.

b) The charger switches on.

c) Any cut-outs remain 'IN'.

d) Normal indications are obtained.

After carrying out a load test, you should check that the batteries are fully charged. If possible, this check should be on the following day.

3. Automatic Switching Cabinet (Permanently on Load Systems Only)

3.1 With the co-operation of the Signaller; switch off the supply to the inverter battery charger.

3.2 Check that a power failure is indicated on the switching cabinet and in the signal box.

3.3 Measure the following power supply values:

a) Input DC volts to the inverter switching cabinet (B110 bus-bar).

b) Output AC volts to equipment.

c) BX110 bus-bar voltage.

3.4 Check that the inverter can maintain the load without any system failures for a period representing 50% of the time that it is expected to cover. After this period, repeat step 3.3.

3.5 Test the load capability of the inverter.

Operate the equipment the inverter supplies.

3.6 Restore the supply to the inverter charger and operate the RESET button on the switching cabinet. Check that normal indications are received on the switching cabinet and in the signal box.

4. Generator Facility (If Fitted)

Some inverters are fitted with a generator socket.

4.1 Plug in a generator that has a large enough load capacity. Start it up and allow it to settle down.

4.2 Check all indications are normal.

4.3 Get the Signallers co-operation and switch off the main power supply.

This can switch Hot and Cold systems to inverter operation. Permanently on systems only indicate a power failure.

4.4 Turn the switch on the switching cabinet to the ‘Generator’ position to connect the generator supply.

4.5 Check that the generator is supplying satisfactory power to the signalling system. Measure the bus-bar voltages.

4.6 Disconnect the generator by turning the switch on the switching cabinet to the ‘Normal’ position and restore the main power supply.

4.7 Check that the inverter switching cabinet and signal box indications are normal.

Some systems require the operating of the reset button on the switching cabinet.

4.8 Switch off and unplug the generator.

END

Includes:	Uninterruptible Power Supplies, and the Powernetics Systems at Cromer

GENERAL

UPS systems contain mains supply voltages of 230V AC. Relevant safety procedures shall be complied with when working on this equipment.

1. UPS Tests (Not the Powernetics Systems at Cromer).

1.1 Check the indications on the unit so that it is working correctly. Investigate and rectify if any problems are found.

1.2 Simulate a power failure by disconnecting a fuse or link to the input supply of the UPS. Observe that the UPS maintains the load and that the relevant indications of a power failure are given.

1.3 Check that the UPS can maintain the load without any system failures for a period representing 50% of the time that it is expected to cover.

Measure the voltage at the start, middle and end of this period. Use these readings to estimate the UPS voltage at 100% of the expected period (where possible use manufacturers discharge graphs).

If the UPS voltage either falls below the lower supply limit or is predicted to do so it shall be reported to your SM(S).

1.4 Reconnect the power to the UPS and observe that the correct indications are given.

1.5 Where the batteries are external to the UPS, check that after the reconnection of power they are charging, NR/SMS/PartB/Test/055 (Secondary Cell Test).

1.6 Where the batteries are internal to the UPS or are maintenance free, they shall be tested and/or replaced at intervals recommended by the manufacturer.

2. Powernetics UPS at Cromer only UPS

2.1 Select “LOAD ON BYPASS” and operate Manual Bypass Switch to the UPS/BYPASS position.

2.2 Switch unit OFF in the correct sequence.

2.3 Move the Manual Bypass Switch to the BYPASS position.

2.4 Remove unit covers, check that loose earth leads are safely taped up.

2.5 Clean the inside of the unit.

2.6 Carry out a visual inspection of the system (Mechanical Electrical and Electronics, including connectors). Rectify and/or report defects.

2.7 Check PCB’s and other components for signs of overheating. Rectify as necessary.

2.8 Check that fans spin freely when operated with finger and that they feel ‘smooth’.

3. Batteries

3.1 Check the state of battery terminals. Clean and grease if required.

4. System Parameters

4.1 Move the Manual Bypass switch to the BYPASS/UPS position and power up the unit in the correct sequence.

4.2 Check that all fans turn at full speed.

4.3 Press the Auto Bypass switch to select “LOAD ON BYPASS” and move the Manual Bypass switch to the UPS position.

4.4 Record the following parameters on the NR/SMS Record Card :

a) Supply Voltage.

b) Charger Float Voltage.

c) Load Current (RMS) – with load on bypass.

d) Load Current (PEAK) – with load on bypass.

e) Output Voltage – with load on bypass.

f) Charger Current – after battery hold-up test.

g) End of discharge voltage.

If any adjustments requiring a load are to be done, then these adjustments shall be made using a dummy load, with the manual bypass switch in the BYPASS/UPS position.

4.5 Check that all displays and alarm functions operate satisfactorily. Rectify as necessary.

The common alarm verification can be done by contacting the Signaller.

5. Battery Hold-up Test

5.1 With the normal system load, switch off the I/P supply isolator and record the total battery voltage against elapsed time on the NR/SMS Record Card.

NOTE: *The duration of this test should be 30 minutes.*

6. Final Actions

6.1 If covers have been removed, select LOAD ON BYPASS on the unit and move the Manual Bypass switch to the UPS/BYPASS position. Switch off the unit in the correct sequence. Check that all fans stop slowly.

6.2 Move the Manual Bypass Switch to the BYPASS position.

6.3 Move the unit back to its normal position if it has been moved. If this is the case, check the tightness of incoming and outgoing connections.

6.4 Move the Manual Bypass Switch to the UPS/BYPASS position and power up the unit in the correct sequence.

6.5 When the unit is up and running, transfer the load onto the inverter.

6.6 Upon completion of the maintenance tasks check that all the breakers are in the ON position and all the panel/cover screws are tight.

END

Includes:	SAFT Air Saline Cells and Dry Cells
Excludes:	CEGASA Air Alkaline Cells

Disposal of old cells shall be as per current environmental policy (SMS/Part/A14).

General

Dry battery cells shall be stored in an upright position in a dry and clean environment.

They can deteriorate in storage therefore they shall be tested as below to check they are in a fit state for use.

SAFT air saline cells shall be set up according to the manufactures instructions taking care that the distilled water used to fill them is within the given limits.

Due to the chemical reaction when these cells are ‘activated’ heat is produced which can make the case of the cell hot.

Care shall be taken when handing newly ‘activated’ cells.

When SAFT air saline and dry primary cells are brought into service, caps and breathing holes should be treated as per the manufactures instructions.

Details about the maintenance and the replacement of CEGASA air alkaline cells can be found in NR/SMS/EL00

1. Primary Cell Test

1.1 Using a suitable meter connect an approved 1Ω shunt across the positive and negative terminals. Test the 1Ω shunt on the meters resistance range before use to check it is not open circuit.

Do not use a train shunt box for this task.

1.2 With the approved shunt in place and the meter on the DC volts range Measure the voltage across each primary cell.

1.3 Do not apply the shunt to the cells whilst they are connected in circuit unless you reach an agreement with the signaller.

Due to load put on the cell apply the shunt only momentarily. Do not continually use the shunt for periods of more than five minutes.

1.4 The cell shall be replaced if the obtained reading is at or below 0.9V

In some cases, it is advisable to replace the cell at a higher threshold (e.g. 1.1V) if there is a possibility due to the loading of the cell of it failing before the next maintenance visit

End

Includes:	System installed in the Seven tunnel
Excludes:	Any other emergency pull cable alarm systems

GENERAL

Carry out these tests in liaison with the Signaller during a no train period preferably under a system possession. It is also necessary to have competent person to observe the indications and alarms

TESTS

Severn Tunnel System (Only)

1. Tunnel Emergency Signals Cold Filament Proving

1.1 Ask the Signaller to operate the tunnel protecting signal on the road open to traffic to a proceed aspect.

1.2 Remove the lamp of the first tunnel emergency signal and observe that the tunnel protecting signal reverts to a red aspect.

1.3 Renew the lamp in the tunnel emergency signal and check that the Signaller is able to operate the tunnel protecting signal on the road open to traffic to a proceed aspect.

1.4 Repeat 1.2 and 1.3 for the other tunnel emergency signals.

1.5 Arrange for the tunnel emergency signals to be illuminated. Measure the lamp voltages and check they are within specification NR/SMS/PartB/Test/021 (Filament Signal Lamp Tests).

2. Pull Cable Test

2.1 Start at the beginning of the system (the Welsh portal of the tunnel). Operate the Pull Cable by physically pulling it.

2.2 Check that the Signaller’s Pull Cable display and alarm unit at Newport PSB and the Technicians unit at Seven Tunnel Junction interlocking indicate the correct Pullkey activation.

2.3 Check that the Pull Cable failed alarm is also sounded and that the red visual indication is illuminated on the Signaller’s panel at Newport PSB.

2.4 In liaison with the Signaller, check that any tunnel protecting signals that were displaying a proceed aspect prior to the test are now displaying a red aspect.

2.5 If visible in the tunnel, check that the tunnel emergency signals have illuminated.

2.6 On the Signaller's panel at Newport PSB check that the tunnel emergency signals are indicating illuminated.

2.7 Check that the two LED indications on the activated Pullkey unit are illuminated.

2.8 Reset the Pullkey unit by rotating the red knob on the front of the unit. Check that the two LED indications extinguish.

2.9 Check that the Pull Cable Display and Alarm units at Newport PSB and Seven Tunnel Junction interlocking are showing a normal indication with no active alarms.

2.10 If visible in the tunnel, check that the tunnel emergency signals have extinguished.

2.11 On the Signallers panel at Newport PSB check that the tunnel emergency signals are indicating extinguished.

2.12 Check that the Signaller's 'Emergency Pull Cable System' failed alarm is now showing a (white) clear indication and that it is possible to operate the tunnel protecting signals and can be cleared to a proceed aspect on the line open to traffic.

2.13 Repeat 2.2 to 2.12 for each of the Pull Cable sections.

<u>Chipping Sodbury Tunnel System (Only)</u>

3. Pull Cable Test

3.1 Start at the beginning of the system. Operate the Pull Cable by physically pulling it.

3.2 Check that the corresponding alarm and indication activate at the controlling signal box and indicate the correct section activation.

3.3 Check that any alarms or indications at any intermediate location are also activated.

3.4 In liaison with the Signaller, check that any tunnel protecting signals that were displaying a proceed aspect prior to the test are now displaying a red aspect.

3.5 Check that the two LED indications on the activated Pullkey unit are illuminated.

3.6 Reset the Pullkey unit by rotating the red knob on the front of the unit. Check that the two LED indications extinguish.

3.7 Check that the corresponding indication at the controlling signal box (and any other intermediate indication point) is showing a normal indication with no active alarms.

3.8 Check that it is possible to operate the tunnel protecting signals can be cleared to a proceed aspect on the line open to traffic.

3.9 Repeat for each of the Pull Cable sections.

END

These tests are only to be carried out during a no-traffic period and with permission of and in liaison with the Signaller.

There are two different systems that enable this function on SSI interlockings, one uses an ESOC relay, and one cuts the feed directly. Westlock Electronic Interlocks perform the function electronically.

With a system using an ESOC relay the Signaller will lose the 'Emergency Signals on Control' for the interlocking to be tested. With systems that cut the feed directly all signals within the interlocking area being tested will return to red.

TESTS

1 Systems using an ESOC Relay

Your SM(S) will issue a temporary strap so that you can carry out this test. Return the strap to your SM(S) when you have completed the test.

Only carry out this test if you have been given authority to do so by your SM(S).

This test enables the Emergency Signals On Control (ESOC) facility to be tested without shutting down the SSI interlocking.

Only applies to an SSI interlocking with an ESOC relay function that places all signals to danger by disconnecting the BX110 interlocking supply. For Westlock systems see section 3.

Carry out this test for each SSI interlocking within the signalling centre control area.

Applying the Temporary Strap

1.1. Check the continuity of the test strap using a meter.

1.2. Using the record copy diagrams; identify the ESOC circuit to be tested.

1.3. Strap-out the front contact of the ESOC relay within the BX110V interlocking supply circuit.

Testing the ESOC Relay

1.4. Connect a suitable meter on a resistance (ohms) range across the spare front contact of the ESOC relay.

1.5. Observe that the ESOC relay red LED is illuminated.

Non Ansaldo Systems Only

1.6. Arrange with the Signaller to press and release the ESOC button for the interlocking to be tested. Observe the following:

a) The red LED goes out when the button is pressed.

b) The ESOC relay de-energises, when the button is pressed. Watch the meter connected across the spare front contact.

c) The red LED illuminates when the button is released.

d) The ESOC relay re-energises not less than 15s after the button is released. Time this from the moment the LED illuminates.

e) Record the ESOC test date, interlocking name and relay energisation time (15s) in the site logbook. If the time is less than 15s or has significantly changed from the last test, tell your SM(S).

Ansaldo Systems Only

1.7. Arrange with the Signaller to press the red button at the bottom left of the Signaller's key pad, then press '0' and then 'ENTER' for the interlocking to be tested. Observe the following:

a) The red LED goes out when the red button is pressed.

b) The ESOC relay de-energises, when the red button is pressed. (Watch the meter connected across the spare front contact).

c) The red LED illuminates when 'ENTER' is pressed.

d) The ESOC relay re-energises not less than 15s after 'ENTER' is pressed. (Time this from the moment the LED illuminates).

1.8. Record the ESOC test date, interlocking name and relay energisation time (15s) in the site logbook.

If the time is less than 15s or has significantly changed from the last test, tell your SM(S).

Recovering the Temporary Strap

1.9. Disconnect and put away the temporary strap.

1.10. Ask a second competent signalling technician to check that the temporary strap has been disconnected from the circuit.

1.11. When you have completed the test on each interlocking, return the test strap to your SM(S).

2 Systems that Directly Cut the Feed

This test will return all signals in the interlocking area to red.

In liaison with the Signalman, this test shall only be undertaken when no trains are in or approaching the interlocking area.

Observe at least one of the trackside signals returning to danger

2.1. Check the Technicians terminal for faults. Rectify as necessary before undertaking the test.

2.2. Arrange with the Signaller for an external signal to be cleared on the interlocking to be tested and check by visual observation that the signal has cleared.

2.3. Ask the Signaller to depress the all signals on button for a minimum of 15 seconds.

2.4. Check that all signals on the associated IECC panel have returned to danger.

2.5. Check that the signal that was cleared outside has returned to red.

2.6. Ask Signaller to release button.

2.7. Check that Signaller can clear signals within the interlocking area.

2.8. Check Technician’s terminal for faults.

3 Emergency Signals on Control (ESOC) Test for Westlock Systems

During the test the Signaller will lose the ESOC for the interlocking being tested. For this reason, only carry out this test during a no-traffic period and with the authority of your SM(S)

Do not attempt to test or disconnect ESOC during an ESOC operation.

While the ESOC Test Wizard is running, no other Technician's Controls can be issued.

The ESOC Test Wizard allows the WESTLOCK Technician's Workstation user to test the Emergency Signals On Control (ESOC) button located on the Signaller's workstation, without actually setting the signals to their most restrictive aspect.

It does this by issuing a 'Disconnect ESOC' technician's request, valid for a maximum of five minutes. This allows the user to operate the ESOC button during this period, and to have the operation detected.

To operate the ESOC wizard and test the ESOC button, proceed as follows:

3.1. At the WESTLOCK Technician's Workstation, click in the Controls menu and select 'ESOC Test Wizard'. The 'Disconnect ESOC' dialogue box is displayed (See Figure 1):

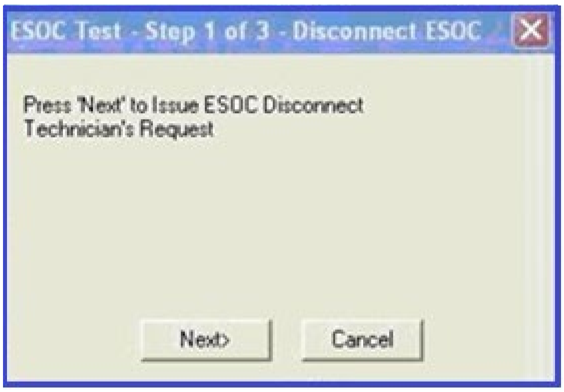

Figure 1 Disconnect ESOC Dialogue Box

3.2. Click 'Next'.

3.3. A Technicians' Request Confirmation dialogue box is displayed (See Figure 2). Type 'CIP' in the 'Confirm' box and click OK to confirm request.

Figure 2 Technician's Request Confirmation Dialogue Box

If the request is not confirmed within a short period, then 'CIP Cancelled Request' result is displayed (See Figure 3):

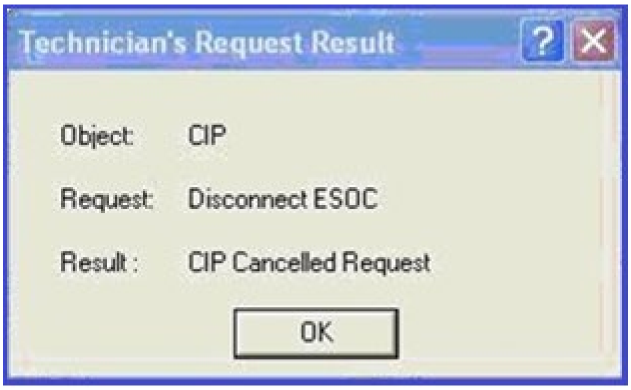

Figure 3 – 'CIP Cancelled Request' Result

If the request confirmation is successful, then 'Request Completed' result is displayed (See Figure 4):

Figure 4 – 'Request Completed' Result

3.4. Click OK. This causes the TW(L) to issue a ‘Disconnect ESOC’ technician’s request.

When the request is successfully completed the ‘Test ESOC’ dialogue box is displayed (See Figure 5) and a 5 minute timer is started and can be seen to count down. Clicking on ‘Cancel’ will close the dialogue box and cancel the procedure.

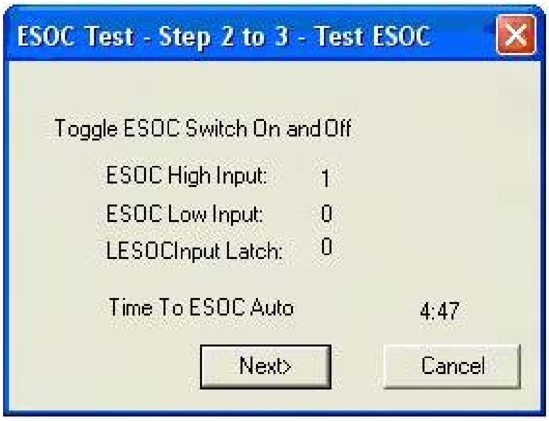

Figure 5 – ESOC Test Dialogue Box

3.5. Observe the dialogue box and check the values shown against the lines are as follows:

a) 'ESOC High Input' 1

b) 'ESOC Low Input' 0

c) 'LESOC Input Latch' 0

3.6. Request the Signaller to operate the ESOC button on his workstation and check the values shown against all three of these lines are updated as follows:

a) 'ESOC High Input' 0

b) 'ESOC Low Input' 1

c) 'LESOC Input Latch' 1

3.7. Request the Signaller to release the ESOC button on his workstation and check the values shown against all three lines in the dialogue box return to their original settings (See Figure 6).

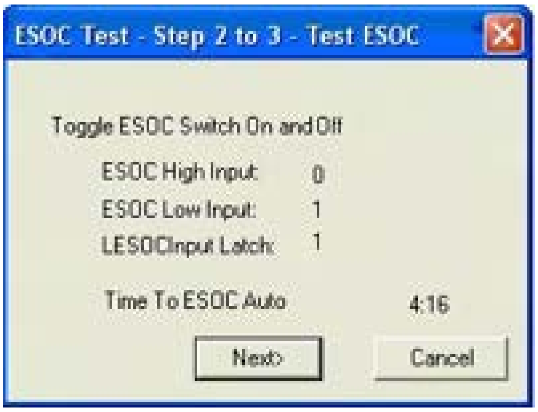

Figure 6 – ESCO Test Dialogue Box

3.8. Repeat 3.3 to 3.5 several times to confirm the operation of the ESOC switch is not intermittent.

It is essential that this is completed within the 5-minute timer period. On completion click 'Next' in the dialogue box.

If the end of the 5-minute period is reached, the ESOC will be automatically re-connected and an 'ESOC Reconnect' dialogue box displayed.

If the signaller presses the ESOC button after this time then the signals will be set to their most restrictive aspect.

The following dialogue box is displayed:

Figure 7 – ESOC Reconnect

3.9. Click on 'Finish'. An 'ESOC Connect' request is issued by the TW(L), and on successful completion the dialogue box is closed, and the procedure is completed.

If the ESOC input is automatically re-connected during the sequence by the 5-minute timer reaching zero, then the ESOC Reconnect dialogue box is displayed. Click on 'OK' in the dialogue box to close it.

Figure 8 ESOC Reconnect Dialogue Box

4 Emergency Signals on Control (ESOC) Test for Smartlock Systems Only

During the test the Signaller will lose the ESOC for the interlocking being tested. For this reason, the test shall only be carried out during a no-traffic period and with the authority of your SM(S).

ESOC testing shall not be undertaken if an axle counter has been reset and a sweep train has yet to prove the section clear.

ESOC testing shall not be undertaken if the support system has failed, as the central interlocking (CIXL) requires the support system to be operational in order to perform a restart.

Operation

4.1 Check the current state of the technician's controls against the written record.

4.2 Request that the Signaller press and immediately release one ESOC button.

4.3 Observe that the power is removed from the CIXL and TICC through all their indications being extinguished for at least 15 seconds.

4.4 Request that the Signaller confirms the standard alarms and behaviour for loss of communication between their panel or VDU system and the interlocking.

4.5 Once power has been seen to restore to the power supplies on both the CIXL and TICC(s), repeat steps 4.2 to 4.4 for each ESOC button provided for the CIXL.

It is not necessary for the system to be allowed to boot fully before performing subsequent tests using other ESOC buttons on the same CIXL.

Post ESOC test

Following the final ESOC button operation the system shall be allowed to complete its power up, which will take 2-3 minutes, at which time the technician will observe communication to restart through flashing of the LED indicators on the CIXL I/O cards.

Once started, the interlocking enters a 4-minute timeout, during which the VIXL within the affected CIXL will declare themselves in ‘Timing Out’ mode (‘tim’ on the Redman card's cyclic display and flashing green / grey on the Support System's CIXL mimic).

At the start of this timeout, the Signaller will observe tracks on the panel flood red, and then recover. Some tracks, near internal interlocking boundaries, may take a few seconds longer to clear.

Route locking will be seen to be applied, but this shall release after a timeout providing track sections are clear (or any occupied sections are behind signals). The system will not respond to requests made by the Signaller until this 4-minute timeout has expired.

Upon expiry of the 4-minute timeout, the technician will see the VIXL enter the on-line mode ("On" on the Redman card's cyclic display and green on the Support

System's CIXL mimic). The Signaller's panel, or VDU based system, will then respond to Signaller requests.

4.6 Request that the Signaller key all points to their current positions, and then to centre (or centre then back to their current position) and cancel any emergency replacement of auto signals which were not in place before the test.

4.7 Verify the applied technician's controls against the written record.

Multiple CIXL

4.8 Repeat steps 4.6 to 4.7 for each CIXL.

END

This test is applicable to all safety related timing function relays including:

- Level crossing timers (HJR, CON JR, reset timers etc).

This is usually done as part of LC annual test.

- Approach Locking Timers (e.g. ALSR).
- Track circuit timers (e.g. TJR).
- Signal approach control timers (e.g. AJR).
- Other Interlocking timers (OJR, USJR etc).

1. Test

1.1 Arrange for the function to be operated to cause the timer relay to run.

1.2 Check the timer operates within the required time cycle (i.e. the time specified on the signalling record). Adjust as necessary.

1.3 Record the result on the NR/SMS record card with the actual time, extent of any adjustment made and initial/ date of test.

If the timer is significantly out of adjustment and it cannot be corrected or replaced immediately, the signaller shall be advised and the relay reported as a fault.

Disconnection of the affected signalling controls shall be considered against the scope of the timing error.

Arrangements shall be made to have the relay replaced.

Point machine cut-out timers (e.g. WJR) are usually tested as part of a point machine service.

End

Includes:	All surge and lightning protection units connected to TDM, FDM, TD, SSI and other electronic equipment

Tests on any line protection units shall not be carried out if there is or the possibility of a thunderstorm in the vicinity of either end of the protected line.

GENERAL

Line Protection Units are used to protect equipment connected by line cables from actual or induced high voltage surges caused by lightning.

They can take the form from a basic ‘spark gap’ contained within a glass tubes to an electronic unit with LED indications.

They are connected between line cables and earth and under normal conditions they provide a very high resistance or open circuit path to earth.

If high voltages are present on the line, they can provide a low resistance or short circuit path to earth preventing the high voltage damaging the equipment they are protecting.

Line protection units can be connected in series or parallel with the line.

Removing the unit can disconnect the equipment from the line; always liaise with the signaller before attempting any disconnections.

Lightning and other types of extreme electrical surges can stress line protection units whilst they are providing protection. Each surge causes a small amount of degradation which can eventually cause the unit to fail.

In most cases, such a failure will not prevent the equipment it is fitted to working correctly, although surge protection can be reduced or lost leaving the system vulnerable to the next surge.

In electronic systems failed line protection units can cause noise levels to increase leading eventually to failure.

To protect against this line protection units shall be tested (or health unit lights inspected) at the next opportunity where it is known that they have been exposed to a lightning strike or other large electrical surge.

If any units are found to be faulty or not working correctly, report the matter as a corrective maintenance item immediately

1. Surge Arrestors AEI 16 or 26 Series Tubes in Bases

1.1 Remove the tube and examine the spark gaps on the base (use a magnifying glass and torch) for cracking or flaking plating.

a) If any is observed the unit is to be replaced.

b) Measure using a suitable meter on the Ohms range that the surge arrestor is not short circuit.

c) Replace the tube back into its base and replace the cover (if fitted).

Surge arrestor spark gaps are pre-set at the factory.

No attempt shall be made to alter this setting.

These are also now known as Semitron 1026 Series.

2. Surge Arrestors Units on 11 Pin Bases (Usually to BR 1937)

2.1 Unplug the unit. For any type, using a suitable meter Measure the resistance across the respective pins to

Check that the diodes, resistors and gas discharge tube are not short or open circuit as appropriate. (Appendix A).

For the Furse Unit, the Furse ESP PTE 002 test device shall be used since it gives a more accurate health check.

3. Line Connection Units (With Glass Covers)

3.1 Disconnect the LCU, remove the glass cover and remove the lightning protector.

3.2 Using a suitable insulation tester (e.g. Megger) on the 50V range connect the leads between the centre ring and one end of the protector. The obtained reading should be very high (MΩ) to infinity.

3.3 Repeat 3.2 with the insulation tester on the 500V range. The obtained reading should now be very low (Ω) to short circuit.

3.4 Reconnect the LCU to circuit.

4. Other Protection Units (not units with LED indications)

This is a generic test for units not covered by the other sections.

4.1 Disconnect the protection unit from the line.

4.2 Using a suitable insulation tester (e.g. megger) on the 50V range connect the leads between the terminal on the unit that is normally connected to the line and the terminal that is normally connected to earth.

The obtained reading should be very high (MΩ) to infinity.

4.3 Repeat 4.2 with the insulation tester on the 500V range. The obtained reading should now be very low (Ω) to short circuit.

700V or 1000V devices fitted to AC track circuits need to be tested at 1000V.

4.4 Reconnect the protection unit to the line.

5. Line Protection Units with LED Indications

Check the status of the line protection units taking action as stated below:

- Green lit only: No Action Required.
- Green and Red Lit: Replace unit within 7 Days.
- Red lit only: Replace unit immediately.

For units with other LED configurations, establish the equivalent indications from the manufacturer's data sheet.

APPENDIX A – Furse Units

Circuits of SSI Surge Protection Units (Numbers refer to base pins) Clippit Unit.

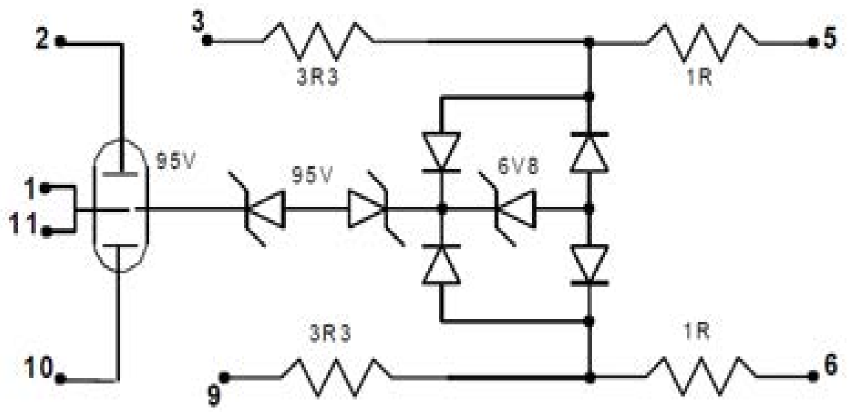

Figure 1 – Furse Unit (post 1994)

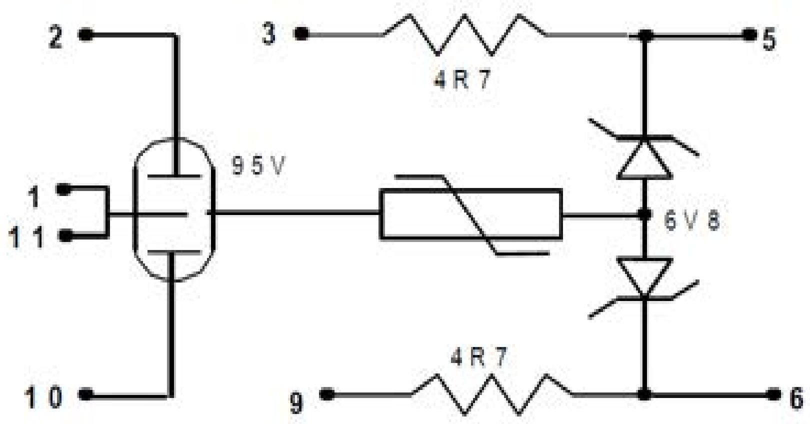

Figure 2 – Pre 1994 Furse units had components with different values.

ISPU

The ISPU is similar to the Furse Unit (post 1994) but has an isolating transformer with its secondary coil connected across pins 5 and 6 and its primary connected across the pair of Zener diodes.

There are several types of ISPU in use, and these differ only in the type of isolating transformer used.

The current model of ISPU is recognised by its orange case.

The ISPU is not interchangeable with the Furse or Clippit units, and shall only be fitted where indicated on the site wiring.

End

System Checks / Tests

1. Signallers Control Console

1.1 Check operation of the handset, headset and desk mic, including the associated PTT switches.

1.2 Check console (Figure 1), headset and loudspeaker volume controls on inbound calls.

Figure 1 – Console Volume Controls

1.3 Check that inbound and outbound audio is clear.

1.4 Check the console LEDs (red Tx LED on outbound calls, green Rx LED on inbound calls), Figure 2.

Figure 2 – Console LEDs

1.5 Check that the connectors to the rear of the console are seated correctly.

1.6 Clean the console touch screen.

2. 2-Wire Dial-Up Interfaces

2.1 Using the Signallers Control Console (Figure 3), carry out a Full System Test over the 4-wire and confirm that a response is received from each site.

2.2 Connect a 2-wire dial-up (the 2-wire icon change to green).

2.3 Disconnect the system 4-wire interface (4-wire icon changes to red).

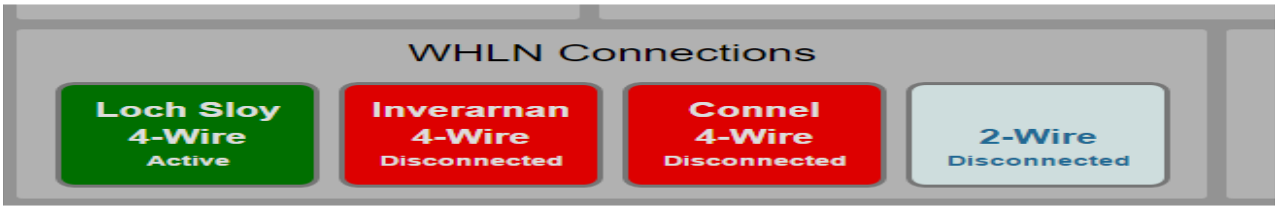

Figure 3 – Signallers Control Console

2.4 Perform audio tests and token exchanges to confirm access to the radio chain.

2.5 Perform a Full System Test over the dial-up and confirm that a response is received from each site.

2.6 Disconnect the dial-up (the 2-wire icon returns to grey).

2.7 Repeat steps 2.1 to 2.6 for each dial-up present on the system.

2.8 Reconnect the 4-wire interface (the 4-wire icon returns to green).

3. Basic Radio Rack Checks

3.1 Dust the cabinet.

3.2 Check that all the shelves and equipment are securely mounted.

3.3 Check that all the cable connectors are secure and undamaged.

3.4 Check the external cables are undamaged and in good condition.

3.5 Check there is satisfactory ventilation around the cabinet and that any cooling fans are working correctly.

3.6 Check any fan filters are clean, replace if necessary.

3.7 Check that the terminal connections to the following 4 items at the back of the rack are secure and in good condition:

a) Wire
b) 2 Wire
c) Signallers console
d) SSI

3.8 Check that the auto test/enable/disable function works for each base station that should be able to be accessed.

4. Extended Radio Rack Checks

4.1 Use the MSS graphing tool to check the system controller internal power supplies, and unit temperature. Compare readings with limits, and with historical data. Identify and report any changes/issues.

4.2 Check that all cables and connectors are secure and undamaged.

4.3 Check that only the green 'Lightning' LED on the power distribution unit (PDU) - (Figure 4) at the rear of the control rack is lit. Investigate if 'polarity' or 'Earth' indicators LEDs are lit. Replace the PDU if necessary.

Figure 4 - PDU

4.4 Check that the 'AC OK' and 'DC OK' LEDs on the two power supply modules (Figure 5) at the front of the rack are green. If any are red, investigate and replace the module if necessary.

Figure 5 – Power Supply Module

4.5 Check that the cooling fans on the PSUs are running and are unobstructed. Clean if necessary.

5. System Current Issues Checks

5.1 Log in to the MSS and select Current Issues.

5.2 Use the filtering options in the left hand pane to select the RETB line of interest, issue types, and timespan.

5.3 Review any logs displayed in the right hand pane. Note any that require immediate attention, e.g. Mains Supply alarm, Battery Low alarm.

6. Network Data Integrity Testing (end-to-end BER testing)

This test is system-invasive and should only be carried out with the co-operation of the signaller.

6.1 Check that the 4-wire interface is connected and all 2-wire dial-ups are disconnected.

6.2 Select MSS > Live System > System Testing > BER.

6.3 Select the radio site at one end of the radio segment of interest from the 'Source ID' pull-down menu, e.g. Mallaig Cell.

6.4 Select the radio site at the other end of the segment from the 'Sink ID' menu, e.g. Banavie SC.

6.5 Click 'Initialise test'.

6.6 Click 'Start test'. A test data packet is sent over the radio network to the radio ID entered. This performs a bit error rate (BER) check.

6.7 If the number of Repeats/Test Runs is set to 1, the following message appears in the small window after a few seconds:

Reply from (for example if using radio unit 1234).

1234, bits: 2176 (expected: 2176), errors: 0

The number of errors should be 0. If it is not, repeat the test a number of times to confirm consistency of bit errors. If bit errors persist then there is a weak point in the radio chain and further testing and diagnostics (e.g. received signal strength (RSS) checks) should be performed over smaller sections to isolate it.

(The number of bits is increment by 2176 for each test run. 'Initialise test' resets the bit counter to 0)

6.8 Repeat for remaining segments of the radio network. Record any weak links that need attention.

6.9 Repeat the BER test with 2-wire dial-up connected instead of the 4-wire, and the Source and Sink IDs reversed.

END

On-Site Power Supply Checks

Mains voltages at 240V AC are present in the power supply. Extreme caution shall be taken (See NR/SMS/PartC/EL00 (Electrical Equipment General) - Hazards Associated with Electrical Supplies.

The equipment includes a UPS function - Power might still be present even though external power has been disconnected.

Batteries are present with large current capacity. Care shall be taken not to short battery contacts. For installations with multiple batteries, do not connect batteries together in any other arrangement other than prescribed in the manufacturer's instructions.

Batteries shall have satisfactory ventilation. Explosive gases are released in charging which shall be allowed to dissipate prior to any works. Keep sparks and flames well away.

UPS Reset Procedure

The UPS (Figure 1) shall be reset, if it has shutdown, before any power is applied to the wall-frame. This would be necessary following:

a) Disconnection and then re-connection of a battery, or
b) If a battery is discharge to a very low level and replaced with a charged battery while no mains is present.

Reset is actioned by pressing the Yellow button mounted within the PSU cabinet. The UPS operation can be verified by an orange LED lights on DRU30 unit.

Figure 1 - UPS

Voltage is also present at the output.

1. Equipment Required

a) PSU cabinet key.

b) Digital multimeter (accurate to 0.1V).

c) Battery tester (e.g. Hioki 3554).

Alarms might be heard on the FSI loudspeaker.

Readings outside of the prescribed limits should fault the equipment.

2. PSU In-Service Health Indication Check

2.1 Open the PSU cabinet and check that the LEDs on all PSU modules (DRE240, DBR60, DRU30, Figure 2) are green.

Figure 2 – PSU Modules

2.2 Visually inspect the battery/batteries for signs of swelling or leakage. Replace if damaged.

2.3 Check that the LEDs on the front of the FSI are as follows: AC: green, BATT: off, PSU: green.

2.4 Measure the voltage across the red and black DIN terminals (Figure 3) on the 'Site Interface' panel.

Expected voltage: 12.5V (Limits 12.0V to 14.0V).

Figure 3 – Red and Black DIN Terminals

3. Basic PSU Output and Alarm Check

3.1 Disconnect the mains.

3.2 Confirm that the Signaller receives a 'mains failure' alarm from the site (displayed on console).

3.3 Check that the FSI LED indications change to: AC: off, BATT: green, PSU: green.

3.4 Check that the LED on the DRU30 unit indicates orange.

3.5 Measure the voltage across the red and black DIN terminals on the 'Site Interface' panel.

Expected voltage: 12.5V (Limits 12.0 to 14.0V assuming healthy state of charge).

3.6 Reconnect the mains.

3.7 Confirm that the Signaller receives a 'mains fault cleared' message from the site.

3.8 Check that the FSI LED indications return to: AC: green, BATT: off, PSU: green.

3.9 Check that the LED on the DRU30 unit returns to green.

4. Battery Tests - Standard Capacity PSU (one 12V battery)

4.1 Disconnect the battery (Figure 4) by separating the grey SBS Anderson connectors inside the cabinet.

Figure 4 – Battery Disconnection

4.2 Visually inspect the battery for signs of swelling or leakage. Replace if damaged.

4.3 Measure the voltage across the battery terminals.

Expected voltage: 12.0V to 13.6V.

4.4 Configure the battery tester for a 20V and 20mΩ range.

4.5 Place the probes onto the battery terminals, wait until a steady reading is established and measure internal resistance.

Model	Good (mΩ)	Warning (mΩ)	Fail (mΩ)
XL12V85	<8.6	8.6-11.5	>11.5

Table 1 – Internal Resistance Values (1)

4.6 If the internal resistance is within the warning zone notify your SM(S).

4.7 If the battery is above the fail limit the battery should be replaced.

4.8 Compare with historical results.

5. Battery Tests - High Capacity PSU (two 6V batteries)

5.1 Disconnect the batteries by separating the yellow SBS Anderson connectors from the "Y" adaptor cable (P1062-CBL-12-03).

Figure 5 – High Capacity PSU

5.2 Visually inspect the batteries for signs of swelling or leakage. Replace if damaged.

5.3 Measure the voltage across the terminals of each battery, in turn.

Expected voltage: 6.0V to 6.8V

5.4 Configure the battery tester for a 20V and 20mΩ range.

5.5 Place the probes onto the terminals of one battery, wait until a steady reading is established and measure internal resistance.

Model	Good (mΩ)	Warning (mΩ)	Fail (mΩ)
XL6V180	<2.4	2.4-3.2	>3.2

Table 2 – Internal Resistance Values (2)

5.6 If the internal resistance is within the warning zone notify your SM(S).

5.7 If the battery is above the fail limit the battery should be replaced.

5.8 Compare with historical results.

5.9 Repeat steps 5.5 to 5.8 for the other battery.

6. Battery Charger Test

6.1 Batteries should still be disconnected following the battery tests above, if required, disconnect the battery(s) by separating the grey SBS Anderson connector inside the PSU cabinet. On a High Capacity PSU, separate the grey connector on the "Y" adaptor cable.

Figure 6 - PSU

6.2 Measure the voltage across the BATT +/- screw terminals on the DRU30 unit (s).

6.3 Expected voltage: 13.6V (Limits: 13.2 to 14.0V).

6.4 Reconnect the battery / batteries to the PSU.

6.5 Reset the UPS (press Yellow button and check Orange LED lights on DRU30 unit).

END

On-Site Antenna System Checks

High power RF signals are generated by the radio equipment. Always disconnect the DC power feed to the fixed station radio or frame before removing or reinstating any connections to the antenna.

Inspection and maintenance of the aerial tower, fall arrest system, antennas, and feeders shall be undertaken as detailed in NR/L2/TEL/30088, by others, and is not part of these checks.

Equipment Required, antenna tester (VSWR meter / Bird Watt Meter).

1. Antenna System Inspection

1.1 Check that the site fixture cabling is secure and undamaged and that all RF connectors are finger tight.

1.2 From ground level, visually inspect the condition of the mast, the security of feeder cables and the antenna elements for obvious defects, including approximate bearing.

2. Antenna VSWR Measurements

2.1 Using the results obtained during Fixed Station Radio & Site Interface Equipment testing - Radio Test – TX Output Power Plot the Forward and Reverse power reading on a VSWR Chart to obtain VSWR Value.

2.2 A VSWR reading in excess of 2.0 should prompt investigation. The reading for each antenna should be compared with historical measurements and the result report by the Maintenance terminal.

2.3 Re-connect the feeder to the bulkhead after making the measurement.

2.4 Repeat for each VHF antenna at the site.

END

Pre-Visit Fixed Site Checks using MSS (Maintenance Support Sub-System)

1. 4-Wire Line Level Check

With the 4-wire connected, check the gains at both ends of the line (Rack and FSI) as follows:

1.1 Select MSS > Live System > System Testing > Line.

1.2 Select the 4-wire interface site, e.g. Crianlarich, from the 'Site' pull-down menu.

1.3 Click 'Test'. The following message should be received:

a) Rx level at Rack: X.X dB, Rx level at FSI: Y.Y dB

b) The target for both reported levels : 0.0 dB (Limits : -1.0 dB to +1.0 dB).

If adjustments are necessary, they are to be made onsite in the FSI configuration.

If the reported Rx level at the Rack is -1.0 dB, then an increase of 1.0 dB is required to the output gain of the FSI.

If the reported Rx level at the FSI is +1.0 dB, a reduction of 1.0 dB in the input gain of the FSI is required.

2. 2-Wire Dial-Up Line Level Check

With the 2-wire connected, check the gains at both ends of the line (Rack and FSI) as follows:

2.1 Select MSS > Live System > System Testing > Line.

2.2 Select the 2-wire interface site, e.g. Buchannan House, from the 'Site' pull-down menu.

2.3 Click 'Test'. The following message should be received:

a) Rx level at Rack: X.X dB, Rx level at FSI: Y.Y dB

b) The target for both reported levels : 0.0 dB (Limits : -1.0 dB to +1.0 dB).

If adjustments are necessary, they are to be made onsite in the FSI configuration. If the reported Rx level at the Rack is -1.0 dB, then an increase of 1.0 dB is required to the output gain of the FSI.

If the reported Rx level at the FSI is +1.0 dB, a reduction of 1.0 dB in the input gain of the FSI is required.

3. Site Interface Parameter Check

3.1 Log in to the MSS, select Graphs and then use the filter in the left hand side pane to select an RETB system, e.g. WHLS.

3.2 Select the site of interest, e.g. Loch Sloy.

3.3 Select ‘Site Interface’, and then select the ‘Supply & temperature’ report type.

3.4 Set the start and end search date and time appropriately, e.g. from date of last service.

3.5 Click ‘Submit’ to plot the graph. Inspect the 3 graphs displayed.

a) Maximum temperature should be < 40 degC.

b) Minimum temperature should be > 0 degC.

c) Supply Voltage should be between 12.0 and 14.0 V.

d) Supply Current should be < 1.0 A.

3.6 Plot the ‘Line levels’ graphs if the site has a line interface. Inspect it for line levels less than 1.0 dB or greater than +1.0 dB.

3.7 Compare the latest FSI graphs with historical data and report any significant changes.

4. Radio Parameter Check

4.1 If present in the Filter tree, select the ‘Cell’.

4.2 Plot the ‘Temperature’ graphs.

a) Maximum Unit and Power Amp temperatures should be < 45 degC.

b) Minimum Unit and Power Amp temperatures should be > 0 degC.

4.3 Plot the ‘Supply & VSWR’ graphs.

a) VSWR is only recorded when the transmitter is active and should be less than 1.7V.

b) Supply Voltage should be between 12.0 and 14.0 V.

c) The supply voltage should dip by no more than 0.5V during keying events.

d) The supply current level when the unit was not keyed should be less than 0.6 A.

e) The supply current level when the unit was keyed should be between 3.5 and 5.0 A, if configured for 25W / +44dBm output power.

4.4 Plot the 'Interference calls' graphs.

Note and report any unusually high numbers of interference events.

4.5 Plot the 'Received signal strength' graph with 'Fixed sites' selected as the 'Linked site'.

4.6 Check the Mean and Min RSS level reported for the neighbouring Link site(s). The levels should not drop below -95 dBm. Variation should be less than 10 dB.

4.7 Repeat steps 4.2 to 4.6 for each Link radio in the Filter tree. In this case the Linked site is the neighbouring Cell.

On-Site Radio Equipment and Site Interface Checks

Equipment Required:

a) Transportable Token Unit (TTU).

b) Digital multimeter.

c) Engineering Terminal laptop and cables.

5. Installation Checks

5.1 Check that all equipment is clean and tidy. Clean and dust as necessary.

5.2 Check the cabling is secure and undamaged and that all RF connectors are finger tight.

5.3 Check the condition of the BT (or other telecom service provider) to railway internal telephone system connection sockets.

5.4 Check the 'RJ' connectors of all inter-unit cables on the fixed site frame are clicked in place. Replace any cables with broken clips.

6. FSI LED Check

6.1 Check that the FSI front panel LEDs indicate a 'No Fault' status as follows (See Table 1):

AC	Green
BATT	Off
PSU	Green
GPS	Green
'Mimic'	Orange (where a radio is fitted)
2W Line	Orange, periodically flashing Red (when the 2-wire dial-up is active)
4W Line	Orange, periodically flashing Red (when the 4-wire interface is active)

Table 1 – FSI Front Panel LEDs

7. FSI Line Level Adjustment (where applicable)

This is only required at sites with 2 or 4-wire line interfaces that require level adjustment, as highlighted by Pre-Visit checks.

7.1 Connect the Engineering Terminal to the FSI using a standard network cable, open the Chrome browser and direct it to 192.168.1.200.

7.2 Select the FSI > Line testing tab.

7.3 If the site has a 4-wire interface, click 'Line test'.

7.4 If the site has a 2-wire dial-up interface, have the signaller connect the dial-up and then click 'Line test'.

Line level figures for Rx Power and Reported Tx Power is displayed in units of dB.

The target for each is 0.0 dB (Limits : -1.0 dB to +1.0 dB).

7.5 If adjustment to either level is necessary, perform the following steps:

a) Click on the FSI > Configuration tab.

b) Click 'Read from device'.

c) To adjust a 4-wire interface, use the '4 wire line output gain' and '4 wire line input gain' controls.

d) To adjust a 2-wire dial-up interface, use the '2 wire line output gain' and '4 wire line input gain' controls.

e) To adjust the 'Rx Power' figure use the INPUT gain (step size = 0.5).

f) To adjust the 'Reported Tx Power' figure use the OUTPUT gain (step size = 1.0).

g) After incrementing or decrementing the required control, click 'Write to device'.

h) Return to the FSI > Line testing tab and re-test the levels. Adjust again if required until both figures are as close to 0.0 as possible.

8. Radio Tests – Reported Parameters

These tests are intrusive or disruptive to network operation and should only be carried out with the co-operation of the signaller.

8.1 Connect the Engineering Terminal to the FSI, if not already connected.

8.2 Click the 'Overview' tab.

8.3 For the first active radio, e.g. a Cell radio, use the 'Tx Key' button to key and de-key the unit.

8.4 The following should be observed on the radio overview (See Table 2):

Supply voltage (idle)	12.0 V min
Supply voltage (keyed)	11.5 V min
Supply current (idle)	0.5 A max
Supply current (keyed)	3.5 to 5.0 A (Tx Power set to +44dBm)
	1.5 to 2.5 A (Tx Power set to +37dBm)
Antenna VSWR (keyed)	< 1.7
Internal temp	> 0 deg C, < 40 deg C
Power amp temp	> 0 deg C, < 45 deg C
Tx disabled	Off (grey) or red for a unit on standby, e.g. White Corries.
Poor VSWR	Off (grey)
Tx protection active	Off (grey)

Table 2 – Radio Overview

8.5 Check that radio is de-keyed (idle).

8.6 Repeat for the remaining radios.

9. Radio Tests – Tx Output Power

Test the output power of each radio fitted on the frame as follows:

9.1 For the first active radio, e.g. a Cell radio, disconnect the antenna feeder at the bulkhead connector at the top of the frame and connect the RF Power Meter to the connector.

9.2 Key the radio using the 'Tx Key' button. Note and record the output power indicated by the meter. This should be within +/-1.5 dB of the 'Tx Power' setting. Record the result for use during Antenna Systems Testing.

9.3 With the radio De-keyed, change the RF Power Meter element for a lower power rated one and using the TX Button, measure reverse power. Record the result for use during Antenna Systems Testing.

9.4 Disconnect the power meter and re-connect the antenna feeder. Check the connector is finger tight.

9.5 Repeat for the remaining radios.

10. Radio Tests – Received Signal Strength

<u>Sites with a main coverage Cell radio</u>

10.1 Check the received signal strength due to the neighbouring Link site(s) as follows:

a) Select the Cell radio tab (Port 1).

b) Select the Port 1 > 'History' tab.

c) Click the 'Rx Signal strength' link in the left hand pane to check that the graph is plotting received signal strength.

d) Click 'Clear graph'.

e) Select the Port 1 > 'RSS testing' tab.

f) Set the 'Neighbour remote key network ID' to the ID of one of the neighbouring Link radio sites.

g) Click 'Tx 5 sec silence' and immediately jump back to the 'History' tab.

h) Observe that the 'Receive' LED lights green and note the Rx signal strength on the graph whilst the Link site is keyed up. Compare the figure with the historical data recorded in the site documentation.

10.2 Repeat this for the neighbouring Link radio site in the opposite direction (where applicable).

Sites with Link radios

10.3 Check the received signal strength due to the Link's neighbouring Cell site as follows:

a) Select a Link radio tab (Ports 2, 3 or 4).

b) Select the 'History' tab.

c) Click the 'Rx Signal strength' link in the left hand pane to check that the graph is plotting received signal strength.

d) Click 'Clear graph'.

e) Select the 'RSS testing' tab.

f) Set the 'Neighbour remote key network ID' to the ID of the neighbouring Cell radio site.

g) Click 'Tx 5 sec silence' and immediately jump back to the 'History' tab.

h) Observe that the 'Receive' LED lights green and note the Rx signal strength on the graph whilst the Cell site is keyed up. Compare the figure with the historical data recorded in the site documentation.

10.4 Repeat this for the remaining Link radios and their neighbouring Cell, where applicable.

11. Radio Tests – Received Signal Strength at Neighbour Sites

Sites with a main coverage Cell radio

11.1 Check the received signal strength at the neighbouring Link site(s) as follows:

a) Select the Cell radio tab (Port 1).

b) Select the Port 1 > 'RSS testing' tab.

c) Set the 'Target network ID' to the ID of one of the neighbouring Link radio sites.

d) Click 'Get Rx signal strength'.

A signal strength response (e.g. -83 dBm) should be received from the Link with the Target ID.

11.2 Compare the figure with the historical data recorded in the site documentation.

11.3 Repeat this for the neighbouring Link radio site in the opposite direction (where applicable).

Sites with Link radios

11.4 Check the received signal strength at the Link's neighbouring Cell site as follows:

a) Select a Link radio tab (Ports 2, 3 or 4).

b) Select the 'RSS testing' tab.

c) Set the 'Target network ID' to the ID of the neighbouring Cell radio site.

d) Click 'Get Rx signal strength'.

A signal strength response should be received from the Cell with the Target ID. Compare the figure with the historical data recorded in the site documentation.

11.5 Repeat this for the remaining Link radios and their neighbouring Cell, where applicable.

END

Includes:	SELC SET 45 -18 Timer (Level Crossing) and SELC 850 AWCU
Excludes:	All other timers

Equipment Identification Image

Figure 1 - SELC SET Digital Timer

Figure 2 - SELC 850 AWCU

1. SELC SET Digital Timer - Set up Process

NOTE: *These style time clocks restrict the output to the yodels when ON, therefore the times need to reflect this, so the ON & OFF times are the opposite to the older mechanical style time clocks.*

1.1 Press PRG button. “SET” appears with first zero flashing.

1.2 Keep pressing OK button until you set the first security code digit which is 4.

1.3 Press PRG button again.

1.4 Enter second security digit which is 7.

1.5 Press PRG again. Timer can now be set up or checked.

1.6 To check what times are inputted without altering; keep pressing PRG which scrolls through each time for ON & OFF. Dashes (--:--) indicate no time is set and timer ignores the setting, so ALL times are to be set.

1.7 To adjust any times; from step 1.5, press PRG until hour or minute flashes and use the OK button (keep pressing or hold down) to adjust each time.

1.8 Set each time (to local instruction, or to standard time which is ON at 2330 and OFF at 0700).

1.9 Keep pressing the PRG button and set ALL times. Note: the days all flash at the bottom, however these do not change as the programmed times are the same for all days of the week. These timers are factory set for specific railway use.

1.10 After each time has been set, press PRG and the following appears; YEAR > MONTH > DAY> TIME.

1.11 Use the OK button to set any of these if wrong.

1.12 Pressing PRG again shows BST/GMT auto change function by either b 1 (ON) or b 0 (OFF). This shall be set to b 1 to enable automatic BST/GMT yearly changes.

1.13 Note: the timer has built in auto leap-year compensation.

1.14 Press PRG to return to main screen.

1.15 Check the main time is correct; the day is correct and according to the time of the day the ON / OFF icon is showing the correct setting.

1.16 Check all the settings again, especially if any have been changed, paying particular attention to the ON and OFF icon making sure the times are correctly matched.

Additional Notes

a) Pressing PRG and OK buttons together results in the timer being reset and clearing all pre-programmed times and settings, and sets the time and date to 00:00 01/01/12, and BST/GMT setting to b 1 (ON).

b) If no buttons are pressed, the screen times out after 30 seconds.

c) Use the MAN button to change the ON / OFF icon over so the yodal's are louder/quieter to test output or to quieten them during engineering work (during the daytime), remember to change back before leaving site if altered.

d) Battery back-up to keep programmed settings is by a lithium cell and lasts up to five years from date of manufacture. It provides up to 12 months back-up if the mains fail. It is NOT user-changeable, so the timer shall be replaced. If exposed to temperatures of +100 degrees Celsius, the cell is liable to explosion. If no LED's lit on buttons, this signifies mains failure.

2. SELC 850 AWCU – Set up process

2.1 Start Set up process (Figure 3).

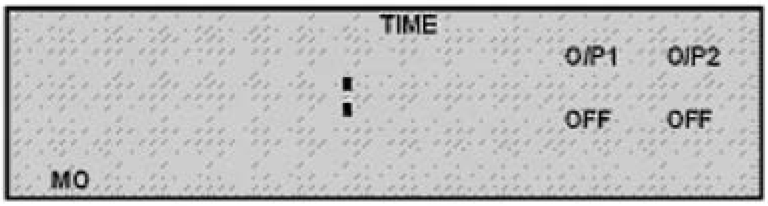

Figure 3 – Start Point

2.2 Output 1 (O/P1) is not used for this application so to move to the Output 2 setup press the MODE button repeatedly until (O/P2) is displayed see (Figure 4).

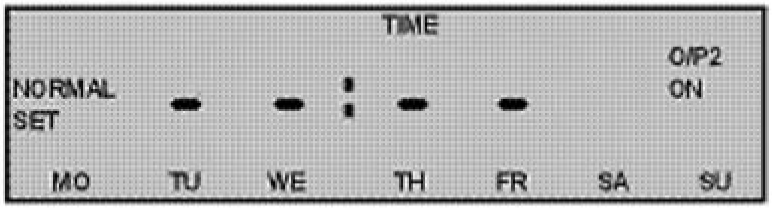

Figure 4 – Output 2 setup

2.3 The hours start to flash (Figure 5)

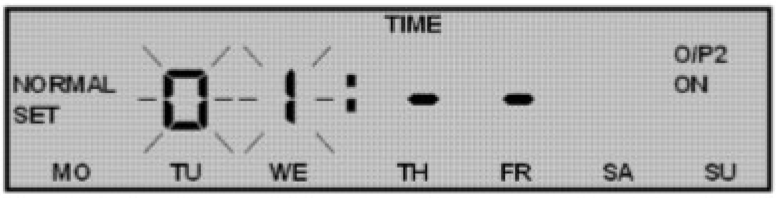

Figure 5 – Hours flashing (Loud)

2.4 Set time for the clock to switch to the loud setting (ON).

2.5 Increase the hours by pressing SET button, once the correct hour is displayed press MODE button once to move to set the minutes (Figure 6).

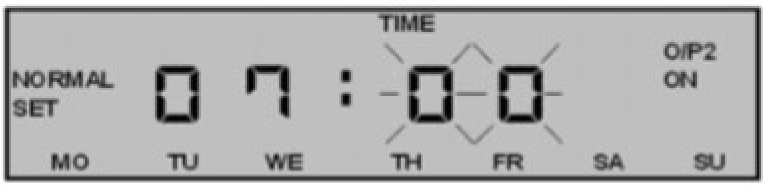

Figure 6 – Minutes flashing (Loud)

2.6 Increase the minutes by pressing the SET button, once the correct minutes are displayed press the MODE button. This causes Monday - Sunday to flash (Figure 7).

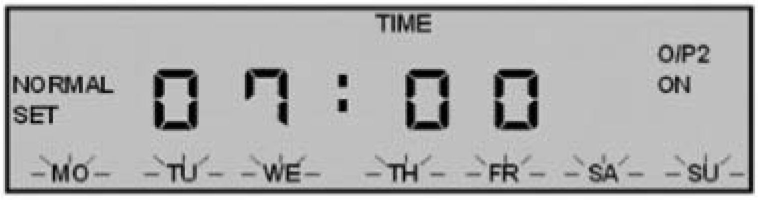

Figure 7 – Days of the week (Loud)

2.7 Press the SET button once, the Monday to Sunday continues to flash now press the SET button again (Figure 8).

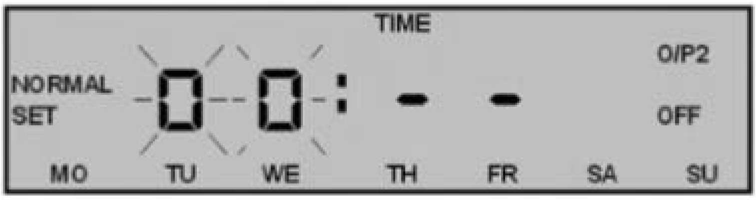

Figure 8 - Set

2.8 Set time for the clock to switch to the quite setting (OFF).

2.9 Increase the hours by pressing the SET button, once the correct hour is displayed press the MODE button once to move to set the minutes.

2.10 Increase the minutes by pressing SET button, once the correct minutes are displayed press MODE button. This causes Monday - Sunday to flash (Figure 9).

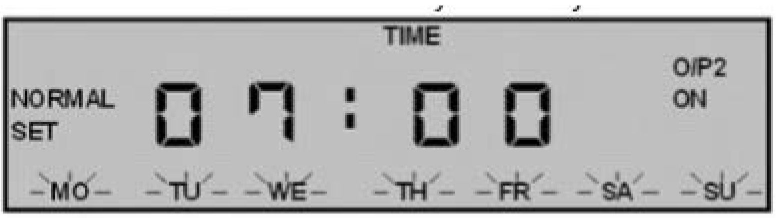

Figure 9 –

2.11 Press SET button once, the Monday to Sunday continues to flash now press SET again.

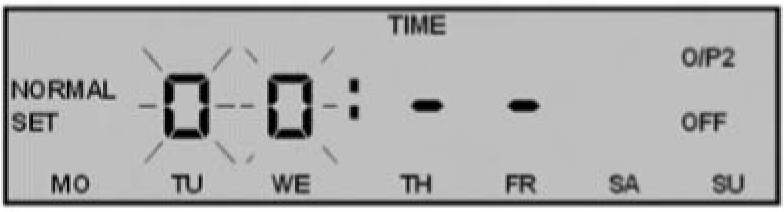

Figure 10

2.12 Set time for the clock to switch to the quite setting

2.13 Increase the hours by pressing SET button, once the correct hour is displayed press MODE button once to move to set the minutes (Figure 10)

2.14 Press the MODE button until Year is displayed (takes several presses)

Figure 11

2.15 Press the SET to increase the (Tens) for the year, once the Tens are correct press the MODE button to move to the (Units). (Figure 11)

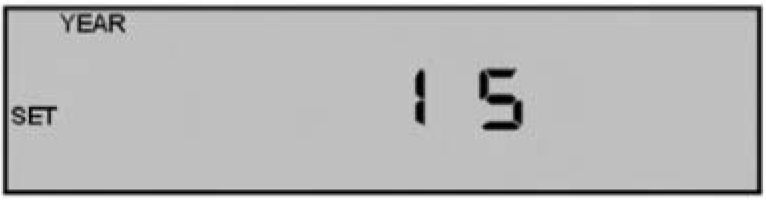

Figure 12

2.16 Press the SET button to increase the (Units) for the year, once the Units are correct press the MODE button to move to Month (Figure 12)

2.17 Press the SET button to increase month (Figure 13)

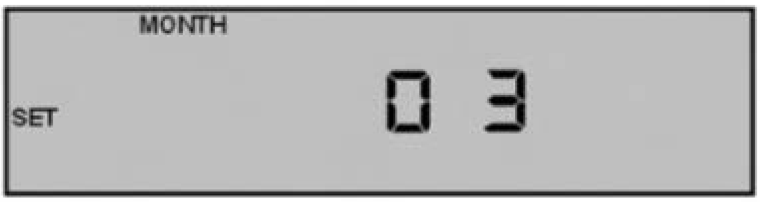

Figure 13

2.18 Once the correct month is displayed press the MODE button to move to the day setup. Press the SET button to increase the day. (Figure 14)

Figure 14

2.19 Once the correct day is displayed press the MODE button to move to the day of the week setup.

2.20 The day of the week flashes (Figure 15)

Figure 15

2.21 Press the SET button once, the day of the week continues to flash. Press the MODE button to move to the next day of the week. Once the current day of the week is displayed press the SET button once.

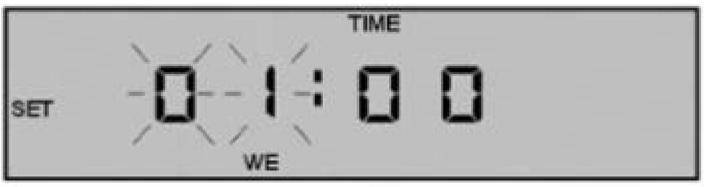

Figure 16

2.22 Press the SET button to increase the hours to display the current hour, then press the MODE button. (Figure 16)

2.23 The minutes now flash

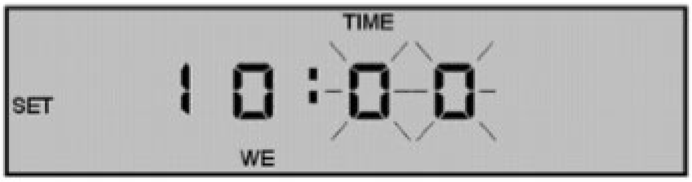

Figure 17

2.24 Press the SET button to increase the minutes to display the current time, then press the MODE button. (Figure 17)

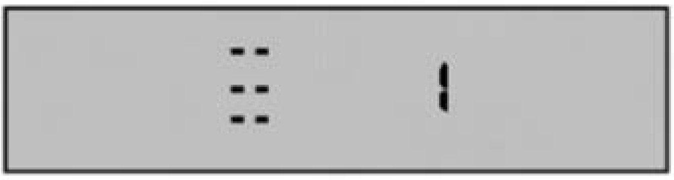

Figure 18

2.25 The screen as displayed above is the setup for BST/GMT changeover and should be left at 1. Press MODE to move to next screen. (Figure 18)

2.26 The next screen is the latitude which should be set at 52. (Figure 19)

Figure 19

2.27 Press the MODE button once which completes the setup and the screen should look something similar to that displayed in Figure 20. (It moves to this screen automatically after a few seconds).

Figure 20

2.28 The state of O/P1 & 2 and the current time is normally displayed.

END

Includes:	All types of Automatic Half Barrier Crossing (AHBC)
Excludes:	All other crossing types

General

Liaise with the Signaller before any tests are carried out.

Check in the crossing control tables for any special controls that affect the automatic control sequence.

On early designs of crossings ATC and Strike in treadle reverse proving is required in the automatic sequence and the crossing sequence starts as soon as the strike in treadles are operated. Check the diagrams.

Where the word EXIT occurs the strike out treadle shall be operated.

On single lines or where bi-directional controls exist, the leaving track circuit shall also be operated.

Where directional proving controls exists the bi-directional strike out treadle shall also be operated in the correct sequence.

Service A - Tests

1. Local Control Sequence

1.1 Operate the LCU to the LOWER position, observe road lights illuminate, audible warnings operate, boom lamps illuminate and the barriers lower.

1.2 Confirm that no trains are approaching.

a) Operate the LCU to the RAISE position.

b) Observe the barriers rise, the road lights extinguish and audible warnings, where designed to sound when barriers are lowered, cease (check diagrams).

1.3 Operate the LCU to the LOWER position, allow the lowering sequence to take place and then operate the LCU switch to the AUTO position.

a) Observe the barriers rise, the road lights extinguish and audible warnings where designed to sound when barriers are lowered cease (check diagrams).

1.4 Close and lock the LCU door.

a) Check the door cannot be locked unless the switch is in the AUTO position.

On BR standard Mk1&2 units (penguin).

b) Check the door cannot be locked unless the AUTO operating lever is in the vertical position and has fully engaged the AUTO button.

2. Automatic Control Sequence

2.1 Simulate an approaching train by shunting a controlling track circuit and/or treadle operation. Observe the following:

a) On double lines 10 seconds elapse before the crossing sequence commences. On single lines the sequence starts immediately.

b) All the amber road signals illuminate, and the audible warnings commence concurrently (Yodel alarms at normal warbling rate).

c) After 3 seconds (5 seconds at older installations) all the amber signals extinguish, and all the red road signals and any pedestrian lights start to flash.

d) After approximately a further 4 seconds (8 seconds at older installations) the barriers commence to lower and the boom lamps illuminate.

e) Check sighting of boom lamps.

f) The barriers take 6 to 8 seconds to reach the fully lowered position.

g) Red road lights and any pedestrian lights continue to be illuminated and flash alternately with the road lights.

h) Audible warnings can continue to sound depending on design (check diagrams).

i) When lowering the final 10 to 15 degrees is damped.

j) Check booms are horizontal when completely lowered.

2.2 Operate the exit function and remove the train simulation if controlling track circuit shunted. Observe the following:

a) The barriers begin to rise.

b) The red road lights extinguish and the audible warnings (depending on design check diagrams) cease before the barriers have reached 45° from the horizontal.

c) The boom lights extinguish when the barriers have reached approximately 81° from the horizontal.

d) The barriers do not take more than 7 seconds to reach the fully raised position of between 81° and 85° from the horizontal.

2.3 Repeat 2.1 and 2.2 for the opposite direction on a single line and the other direction on double lines.

3. Double Lines Second Train Approaching Sequence

3.1 Simulate a train striking in on line one as per 2.1.

3.2 Simulate a second train striking in on line two.

Observe the following:

a) The barriers remain lowered.

b) The road lights and any pedestrian lights continue to flash.

c) The audible warning rate where designed to sound when barriers are lowered continues at the normal rate (check diagrams).

3.3 Operate the exit function and remove the simulation for the first train if controlling track circuit shunted. Observe the following:

a) The barriers remain lowered.

b) The road lights and any pedestrian lights continue to flash.

c) The audible warning rate where designed to sound when barriers are lowered changes to the increased rate (check diagrams).

3.4 Operate the exit function and remove the simulation for the second train. Observe that the sequence is the same as described in 2.2.

3.5 Repeat steps 3.1 to 3.4 for a train striking in on line two first and a second train striking in on line one.

3.6 Where possible, observe the correct crossing sequence during passage of a train(s).

4. Indications

4.1 Check that the correct indications are received in the monitoring signal box throughout a local control and automatic sequence.

Situation	Indication
Automatic control, no train approaching or no train	Barriers Raised
Crossing on Local Control or any barrier proving contact	Barriers Working Barriers
Automatic control, train approaching or train simulation	Barriers Working

Indications can be by needle instrument or lamp depending on the age of the crossing.

*: Check the diagrams for the contacts in the barrier proving circuit ((Xing)KR).
**: The barriers failed indication occur after 180 seconds on a single line or 240 seconds on a double line along with an audible warning.

Service B – Tests

These tests are for the full annual test of the crossing. NR/SMS/PartD/Index lists the indexes and references to the A4 format (with tick boxes) of this test for the use of the person testing the crossing.

END

Includes:	All types of Automatic Barrier Crossing Controlled Locally (ABCL)
Excludes:	All other types of Level Crossing

Liaise with the Signaller before any tests are carried out. Check in the crossing control tables for any special controls that affect the automatic control sequence. Where the word EXIT occurs, operate the strike out treadle.

On single lines or where bi-directional controls exist, operate the leaving track circuit.

Where directional proving controls exists operate the bi-directional strike out treadle in the correct sequence.

The following abbreviations are used in this service:

- DRL: Driver's Red Light.
- DWL: Driver's White Light.

SERVICE A TESTS

1. Local Control Sequence

1.1 Operate the LCU to the lower position:

a) Observe road lights illuminate, audible warnings operate, crossing headlights illuminate and the barriers lower.

b) Check the DWLs do not illuminate.

1.2 Confirm that no trains are approaching. Operate the LCU to the raise position:

- Observe the barriers rise, the road lights extinguish, the crossing headlights extinguish, and audible warnings cease.

1.3 Operate the LCU to the lower position, allow the lowering sequence to take place and then operate the LCU switch to the auto position:

a) Observe the barriers rise, the road lights extinguish and audible warnings cease.

b) Check that all DRL are flashing.

1.4 Close and lock the LCU door. Check the door cannot be locked unless the switch is in the auto position.

1.5 Check that the DRL is flashing for all signalled directions.

2. Automatic Control Sequence

2.1 Observe, with no train approaching, all DRLs are flashing.

2.2 Simulate an approaching train by shunting a controlling track circuit. Observe the following:

a) On double lines 10 seconds elapse before the crossing sequence commences. On single lines the sequence starts immediately.

b) All the amber road signals illuminate, and the audible warnings begin at the same time (Yodalarms at normal warbling rate).

c) After 3 seconds all the amber signals extinguish and all the red road signals and any pedestrian lights start to flash.

d) The crossing headlights illuminate the crossing at the same time the red road lights commence to flash.

e) After approximately a further 4 seconds the barriers commence to lower and the boom lamps illuminate.

f) Check the sighting of the boom lamps.

g) As the barriers commence to lower, the driver's red light extinguishes and the DWL commences to flash for the direction where the train simulation was applied. The DRL continues for the opposing directions.

h) The barriers take 6 to 8 seconds to reach the fully lowered position.

i) The crossing headlights, red road lights and any pedestrian lights continue to be illuminated and audible warnings continue to sound.

2.3 Operate the exit function and remove the train simulation. Observe the following:

a) The barriers begin to rise.

b) The DWL for the direction where the simulation was applied extinguishes and the DRL (if provided) commences to flash.

c) The red road lights and crossing headlights extinguish and the audible warnings cease when the barriers have reached approximately 45° from the horizontal.

d) The boom lights extinguish when the barriers have reached approximately 81° from the horizontal.

e) The barriers do not take more than 7 seconds to reach the fully raised position of between 81° and 85° from the horizontal.

2.4 Repeat steps 2.2 and 2.3 for the opposite direction on a single line and the other direction on double lines.

3. Double Lines Second Train Approaching Sequence

3.1 Simulate a train striking in on line one as per 2.2.

3.2 Simulate a second train striking in on line two. Observe the following:

a) The barriers remain lowered.

b) The road lights and any pedestrian lights continue to flash.

c) The audible warning rate continues at the normal rate.

d) The crossing headlights continue to illuminate.

3.3 Operate the exit function and remove the simulation on line one. Observe the following:

a) The barriers remain lowered.

b) The road lights and any pedestrian lights continue to flash.

c) The audible warning rate changes to the increased rate.

d) The crossing headlights continue to illuminate.

e) The DWL for the direction of the simulation on line one extinguishes and the DRL commences to flash.

f) The DRL for the simulation on line two extinguishes and the DWL commences to flash.

3.4 Operate the exit function and remove the simulation on line two. Observe that the sequence is the same as described in 2.3.

3.5 Repeat steps 3.1 to 3.4 for a train striking in on line two first and a second train striking in on line one.

3.6 Where possible, Observe the correct crossing sequence during passage of a train(s).

SERVICE B TESTS

These tests are for the full annual test of the crossing. NR/SMS/PartD/Index lists the indexes and references to the A4 format (with tick boxes) of these tests for the use of the person testing the crossing.

APPENDIX A - Indications

Table 1 lists the driver indications displayed throughout a local control and automatic sequence.

<table>
<tr><th>Situation</th><th>Indication</th></tr>
<tr><td>Automatic control, no train approaching, or no train simulation applied</td><td rowspan="2">DRL Flashing DWL Extinguished</td></tr>
<tr><td>Crossing on operating on Local Control</td></tr>
<tr><td>Automatic control, train approaching or train simulation applied, barriers started to lower</td><td>DRL Extinguished DWL Flashing</td></tr>

</table>

Table 1 – Driver Indications Table

Notes:

The DWL should only operate for the direction in which the train is approaching or the train simulation has been applied. The DRL should be operating for all other directions.

* Check the diagrams for the contacts in the DWL control circuit (this includes the (PO)PR function).

END

Includes:	All types of Automatic Open Crossing Locally Monitored (AOCL).
Excludes:	All other types of Crossing

General

Liaise with the signaller before any tests are carried out.
Check in the crossing control tables for any special controls that affect the automatic control sequence.

On early designs of crossings ATC and Strike in treadle reverse proving is required in the automatic sequence and the crossing sequence starts as soon as the strike in treadles are operated. Check the diagrams.

Where the word EXIT occurs, the strike out treadle shall be operated.
On single lines or where, bi-directional controls exists, the leaving track circuit shall also be operated.

Where directional proving controls exists the bi-directional strike out treadle shall also be operated in the correct sequence.

The following abbreviations are used in this service:

- DRL: driver's red light.
- DWL: driver's white light.

Service A

Tests

1. Local Control Sequence (If Provided)

1.1 Operate the LCU to the On position and Observe the road lights and audible warnings operate.

1.2 Check that the DWLs do not illuminate.

1.3 Confirm that no trains are approaching

1.4 Operate the LCU to the Off position and Observe the road lights extinguish and audible warnings cease.

1.5 Operate the LCU to On position, allow the sequence to complete then switch to the Auto position. Observe the road lights extinguish and audible warnings cease.

On modern installations the switch can be put straight to the auto position and the door locked.

1.6 Close and lock the LCU door. Check the door cannot be locked unless the switch is in the Auto position.

1.7 Check (if applicable) that the DRL is flashing for all signalled directions.

2. Automatic Control Sequence

2.1 Observe, with no train approaching, all DRLs (if applicable) are flashing.

2.2 Simulate an approaching train by shunting a controlling track circuit. Observe the following:

a) On double lines 10 seconds elapse before the crossing sequence commences. On single lines the sequence starts immediately.

b) All the amber road signals illuminate and the audible warnings commence concurrently (Yodel alarms at normal warbling rate).

c) After 3 seconds (5 seconds at older installations), all the amber signals extinguish and all the red road signals and any pedestrian lights start to flash.

d) The crossing headlights illuminate the crossing at the time the red road lights commence to flash.

e) The DRL (if applicable) extinguishes and the DWL commences to flash for the direction where the train simulation was applied. The DRL (if applicable) continues for the opposing directions.

2.3 Operate the exit function and remove the train simulation. Observe the following:

a) The road lights, any pedestrian lights and audible warnings cease immediately.

b) The DWL for the direction where the simulation was applied extinguishes.

c) The DRL (if applicable) commences to flash.

d) Repeat steps 2.2 and 2.3 for the opposite direction on a single line and the other direction on double lines.

3. Double Lines Second Train Approaching Sequence

3.1 Simulate a train striking in on line one as per 2.2.

3.2 Simulate a second train striking in on line two. Observe the following:

a) The road lights and any pedestrian lights continue to flash.

b) The audible warning rate continues at the normal rate.

c) The crossing headlights continue to illuminate.

3.3 Operate the exit function and remove the simulation for the first train. Observe the following:

a) The road lights and any pedestrian lights continue to flash.

b) The audible warning rate changes to the increased rate.

c) The ATC signs (if Illuminating) illuminate, flash and the words are correct.

d) The crossing headlights continue to illuminate.

e) The DWL for the direction of the simulation on line one extinguishes and the DRL (if applicable) commences to flash.

f) The DRL (if applicable) for the simulation on line two extinguishes and the DWL commences to flash.

3.4 Operate the exit function and remove the simulation on line two. Observe that the sequence is the same as described in 2.4.

3.5 Repeat steps 3.1 to 3.4 for a train striking in on line two first and a second train striking in on line one.

3.6 Where possible, observe the correct crossing sequence during passage of a train(s).

Service B

Tests

These tasks are for the full annual test of the crossing. NR/SMS/Part/D lists the indexes and references to the A4 format (with tick boxes) of these tasks for the use of the person testing the crossing.

APPENDIX A-INDICATIONS

The following table lists the driver indications displayed throughout a local control and automatic sequence.

Situation	Indication
Automatic control, no train approaching or no train simulation applied	DRL Flashing* DWL Extinguished
Crossing on operating on Local Control	
Automatic control, train approaching or train simulation applied, road lights operating	DRL Extinguished* DWL Flashing
Crossing operated by train simulation, DWL operating, any DWL proving contact broken, power off**	DRL Flashing* DWL Extinguished

Table 1 – Driver indications

The DWL should only operate for the direction in which the train is approaching or the train simulation has been applied. The DRL should be operating for all other directions.

*: The DRL indications are applicable to installations that are fitted with DRL/DWL units

**: Check the diagrams for the contacts in the DWL control circuit (this includes the (PO)PR function).

End

Includes:	All types of Automatic Open Crossing Remotely Monitored (AOCR).
Excludes:	All other types of Crossing

General

Liaise with the signaller before any tests are carried out Check in the crossing control tables for any special controls that affect the automatic control sequence.

Where the word EXIT occurs the strike out treadle shall be operated.

On single lines or where bi-directional controls exist, the leaving track circuit shall also be operated.

Where directional proving controls exists the bi-directional strike out treadle shall also be operated in the correct sequence.

Service A

Tests

1. Local Control Sequence

1.1 Operate the LCU to the on position:

1.2 Observe road lights and audible warnings operate.

1.3 Confirm that no trains are approaching

1.4 Operate the LCU to the off position and Observe the road lights extinguish and audible warnings cease.

1.5 Operate the LCU to the on position, allow the sequence to complete then switch to the auto position.

1.6 Observe the road lights extinguish and audible warnings cease.

1.7 Close and lock the LCU door. *Check* the door cannot be locked unless the switch is in the auto position.

2. Automatic Control Sequence

2.1 Simulate an approaching train by shunting a controlling track circuit. *Observe* the following:

a) On double lines 10 seconds elapse before the crossing sequence commences. On single lines the sequence starts immediately.

b) All the amber road signals illuminate and the audible warnings commence concurrently (Yodel alarms at normal warbling rate).

c) After 3 seconds all the amber signals extinguish and all the red road signals and any pedestrian lights start to flash.

2.2 Operate the exit function and remove the train simulation and *observe* the road lights, any pedestrian lights and audible warnings cease immediately.

2.3 Repeat steps 2.1 and 2.2 for the opposite direction on a single line and the other direction on double lines.

3. Double Lines Second Train Approaching Sequence

3.1 Simulate a train striking in on line one as per 2.1

3.2 Simulate a second train striking in on line two. *Observe* the following:

a) The road lights and any pedestrian lights continue to flash.

b) The audible warning rate continues at the normal rate.

3.3 Operate the exit function and remove the simulation on line one. *Observe* the following:

a) The road lights and any pedestrian lights continue to flash.

b) The audible warning rate changes to the increased rate.

3.4 Operate the exit function and remove the simulation on line two. *Observe* the road lights, any pedestrian lights, and audible warnings cease immediately.

3.5 Repeat steps 3.1 to 3.4 for a train striking in on line two first and a second train striking in on line one.

3.6 Where possible, *observe* the crossing sequence during passage of a train.

4. Indications

4.1 Check that the correct indications are received in the monitoring signal box throughout a local control and automatic sequence.

Situation	Indication
Automatic control, no train approaching or no train simulation applied	In Order* In Order**
Crossing on Local Control or any crossing proving contact broken #2	No Illumination* No Legend** Failed/Local Control* #1 No Legend** #1
Automatic control, train approaching or train simulation applied	No Illumination* No Legend**

Table 1 – Signal box indications

Indications can be by needle instrument or lamp depending on the age of the crossing.

* : Indications given by a lamp type indicator.

** : Indications given by a needle type indicator.

#1: The crossing failed indication occurs after 180 seconds on a single line or 240 seconds on a double line along with an audible warning.

#2: Check the diagrams for the contacts in the crossing proving circuit.

SERVICE B TESTS

These tests are for the full annual test of the crossing. NR/SMS/Part/D lists the indexes and references to the A4 format (with tick boxes) of these tests for the use of the person testing the crossing.

End

Includes:	All types of Miniature Stop Light Crossing (MSL)
Excludes:	All other types of Crossing

General

Check in the crossing control tables for any special controls that affect the automatic control sequence. Where the word EXIT occurs the strike out treadle (where provided) shall be operated.

If gates or barriers are found open, close to roadway and inform your SM(S).

Tests

1. Sequence Test

1.1 Simulate an approaching train by shunting a controlling track circuit. Observe the following:

a) The green lamps on all light units extinguish and the red lamps illuminate.

b) The audible warnings (if provided) sound.

1.2 Operate the exit function and remove the train simulation. Observe the following:

a) The red lamps on all light units extinguish and the green lamps illuminate.

b) The audible warnings (if provided) cease.

1.3 Repeat steps 1.1 and 1.2 for all other directions where controls are provided.

2. Double Lines Second Train Approaching Sequence

2.1 Simulate an approaching train as in 1.1 on line one.

2.2 Simulate a second train striking in on line two.

2.3 Operate the exit function for the train simulation on line one, observe the following:

- The green lamps on all light units stay extinguished and the red lamps stay illuminated.
- The audible warnings (if provided) changes to the increased rate.

2.4 Operate the exit function for the train simulation on line two and observe that the sequence is as 1.2.

2.5 Repeat steps 2.1 to 2.4 for a train striking in on line two first and a second train striking in on line one.

2.6 Where possible, observe the correct crossing sequence during passage of a train(s).

These tests are for the full annual test of the crossing. NR/SMS/Part/D lists the indexes and references to the A4 format (with tick boxes) of these tests for the use of the person testing the crossing.

End

Includes:	Manually Controlled Barriers (MCB) & all Derivatives including MCB-CCTV, MCB- OD, MCB-RB, Traincrew Operated Barriers (TOB)
Excludes:	CCTV equipment (see NR/SMS/PartC/TV01 & TV02)

GENERAL

For Signaller's controls at newer installations that have a STOP button on the control unit, one press of the LOWER or RAISE button commences the requested sequence. However some installations have been modified so that the LOWER button has to be kept pressed to continue the sequence. If you are in doubt, check the diagrams or ask your SM(S).

At older installations without a STOP button the LOWER button has to be kept pressed to continue the sequence, but only one press of the RAISE button is required for the raise sequence.

Older MCB crossings do not have local control units. At these sites, the tasks against the LCU do not apply.

At MCB-CCTV installations, the sequence cannot be initiated unless a picture on the monitor is called.

Some MCB-CCTV installations have an auto lower facility (these usually have additional Signaller audible warnings) and/or an auto raise facility.

SERVICE A TESTS

1. Barrier Operation Sequence Signallers Controls

At MCB, MCB-CCTV and MCB-RB crossings the following sequence may be performed by yourself, with permission of the Signaller, or observed whilst the Signaller operates/auto lower initiates the barrier sequence for the passage of a train.

At MCB-CCTV installations, observation can be via the crossing monitor (with on-site assistance for the audible warnings.)

At MCB-OD the tests shall be carried out at site.

1.1 Observe the following sequence as the barriers are lowered:

a) All the Amber lights illuminate and show a steady light.

b) The audible warnings (if fitted) sound when the amber lights illuminate and continue until all the barriers have fully lowered.

c) After approximately 3 to 5 seconds the amber lights extinguish, and all the red lights begin to flash.

d) After approximately 4 to 6 seconds after the red lights have started to flash the barriers begin to lower. At installations with four barriers, check that the nearside barriers (YN& ZN) lower first and are completely lowered before the offside barriers (YO & ZO) begin to lower.

e) The boom lights on each barrier illuminate when the barrier is approximately 80° from the horizontal.

f) Each barrier takes between 6 to 10 seconds to completely lower. Confirm barrier damping (if fitted) is effective when the barrier is approximately 10° from the fully lowered position.

g) The audible warnings (if fitted) cease to sound when all the barriers have fully lowered.

1.2 At MCB, MCB-CCTV and MCB-RB, check that protecting signals cannot be cleared until the ‘crossing clear’ function is operated.

1.3 At MCB-OD crossings, check that, if the crossing is clear, the obstacle detector allows protecting signals to clear approximately 4 seconds after all barriers are detected down (check the DOWN indication in signal box goes from flashing to steady white).

Check that an obstruction on the crossing prevents crossing clear being given (DOWN indication remains flashing, does NOT go steady).

After the barrier management sequence has completed (exit barriers raise and stay raised if crossing is occupied). The Signaller receives an alarm approximately 30 seconds after the exit barriers have raised (by AUTO indication flashing plus an audible alarm).

1.4 Check at MCB-CCTV installations that have auto raise, if this is selected the monitor picture is extinguished when the crossing clear function is operated.

1.5 Observe the following sequence as the barriers are raised:

a) The raise sequence cannot be initiated unless protecting signals are at red.

b) All the barriers begin to rise simultaneously and take 4 to 10 seconds to reach the fully raised position at between 83° and 85° from the horizontal.

c) The flashing red lights continue to show until the barriers have reached approximately 45° from the horizontal.

d) The boom lights extinguish when all the barriers have passed 80° from the horizontal.

2. Additional Checks for MCB-CCTV installations with Auto Lower Facilities

2.1 Check (if provided) an audible warning is given, and a picture is called on the monitor when the crossing sequence is initiated.

2.2 Check (if provided) an audible warning is given when all barriers are fully lowered.

3. Barrier Sequence Operation (Local Control)

These tests are 'If Provided'. At installations that have Auto Lower and/or Auto Raise.

3.1 Check that the manual position is selected for these tests.

3.2 In liaison with the Signaller open the LCU door and switch to local control.

If door proving is fitted, the Signaller receives a failed indication when the door is opened, otherwise it fails when local control is taken.

3.3 Carry out steps and observations as per 1.1 and 1.5.

NOTE: *Because the crossing is now in LCU mode, it will also be failed and so it is not possible for Crossing Clear to be registered or for the protecting signals to clear.*

3.4 Return the crossing control back to the Signaller.

At newer installations when giving local control back, the barriers shall be in the lowered position, then close and lock the LCU door.

The Signaller shall first select LOWER/DOWN (to correspond their controls to the actual barrier position) and can then operate the barriers to the raised position which proves that they have regained control.

4. Barrier Sequence Operation (TMOB)

4.1 Check that the barrier sequence is initiated when the controlling TC is occupied, and the driver's plunger are operated.

4.2 Check that the lowering sequence is as step 1.1.

4.3 Check the DCI (white light) operates only when all barriers are fully lowed for the direction of the applied simulation.

4.4 With the controlling TCs clear, check the raising sequence is as 1.3.

4.5 Check the DCI (white light) is extinguished.

5. Indications (Signallers Controls)

5.1 Check that the correct indications (Table 1) are received on the Signaller's panel throughout a lowering and raising sequence.

SITUATION	INDICATION
Barriers Raised	Barriers Raised
Lower button operated, red road lights operating, barriers raised	Barriers Raised Y Road Lights Z Road Lights
Lower button operated, red road lights operating, barriers lowering	Y Road Lights Z Road Lights
Barriers Lowered	Barriers Lowered Y Road Lights Z Road Lights Crossing Clear*
Barriers Rising	None till all barriers raised; then Barriers Raised
Local Control (if provided)	Barriers Failed

Table 1 – Signallers Indications

* If provided, this will be flashing until the function is operated.

6. Local Control Indications (if provided)

6.1 Check that the correct indications (Table 2) are received on the local control unit throughout a lowering and raising sequence.

Situation	Indication
Signaller Control	No Indication
Local Control	Barriers Raised
Barriers Lowering	No Indication
Barriers Lowered	Barriers Lowered
Barriers Rising	No Indication
Barriers Raised	Barriers Raised

Table 2 – Local Control Indications

SERVICE B TESTS

These tests are for the full annual test of the crossing.

NR/SMS/Part/D lists the indexes and references to the A4 format (with tick boxes) of these tests for the use of the person testing the crossing.

END

Includes:	All types of On Call Barriers (OCB)
Excludes:	All other types of Barrier

General

Check that the signaller receives the correct indications throughout the barrier operation sequence.

Service A

Tests

1. Barrier Operation Sequence

The following sequence can be performed by the technician with permission of the signaller or observed whilst the signaller operates the barriers for the passage of a train.

1.1 Operate the lower switch/button and *Observe* the following:

a) The audible warnings sound.

b) The Barriers commence to fall 8 to10 seconds after the audible warnings commence and are fully lowered in a further 8 to15 seconds.

c) The booms lights illuminate when the barriers are approximately 80° from the horizontal.

d) The audible warnings continue to sound until both barriers are fully lowered.

1.2 Operate the raise switch/button and *Observe* the following:

a) The barriers commence to rise.

b) The boom lights extinguish when the barriers have passed 80° from the horizontal.

c) The barrier cut-off is effective when the barriers reach the fully raised position of between 83° and 85° from the horizontal.

d) The barriers take 8 to 15 seconds to reach the fully raised position.

Service B

Tests

These tests are for the full annual test of the crossing. NR/SMS/Part/D lists the indexes and references to the A4 format (with tick boxes) of these tests for the use of the person testing the crossing.

End

Includes:	Single white light units.
Excludes:	All other types of Crossing

Service A

1. Sequence Test

1.1 Train shunt the controlling track circuits and Observe that the lamps extinguish. Remove the train shunt and observe that the lamps illuminate.

Directional and/or route setting controls can affect the operation of these lights. If in doubt, ask your SM(S).

End

Includes:	Mechanically Operated Gates, Locked Gates, Keylock Operated Gates, Hand Operated Gates
Excludes:	All other Gates

SERVICE A TESTS

1. Mechanically Operated Gates

The sequence in 1.2 may be performed by yourself with permission of the Signaller or observed whilst the Signaller operates the gates for the passage of a train.

1.1 With the gates closed to rail traffic and open to road traffic, check that the gate stops are effective in holding the gates.

1.2 Operate the gates so that they are open to rail traffic and closed to road traffic. Check the following:

a) Audible warnings (if provided) operate correctly.

b) The release and gate stop levers operate without excessive force being required.

c) The gate stops fall and rise correctly in the correct sequence.

d) The gates operate without excessive force required on the operating mechanism.

e) The gates do not catch on the road surface during any part of their movement.

f) On completion on their movement the gates are held effectively in the gate stops.

g) The gate stop levers are correctly locked in the frame.

1.3 Repeat 1.2 operating the gate so that they are closed to rail traffic and open to road traffic.

1.4 Check that any locked wickets gates are effective when the locking lever is reversed in the frame. When locked, the gate should not be able to be opened sufficiently to allow a person to pass.

2. Locked Gates (Black's Locks & Bottle Locks)

These tests shall be carried out in liaison with the Signaller or crossing keeper.

2.1 With the gates closed to rail traffic and open to road traffic. Check the following:

a) The gate lock is effective in holding the gates.

b) The frame release lever is locked in the frame.

2.2 Operate the gates so that they are open to rail traffic and closed to road traffic. Check the following:

a) The gates swing without excessive force being required.

b) The gates do not catch on the road surface during any part of their movement.

2.3 When the gates are closed to road traffic, check the following:

a) The bolt enters the locking mechanism smoothly and can be turned without excessive force being required.

b) When both gate bolts are fully engaged in the locking mechanism, the frame release lever can be reversed.

c) When the frame release lever is fully reversed, the gate bolts are locked in the locking mechanism.

2.4 Place the release lever normal in the frame and check the gate bolts can be turned and withdrawn from the locking mechanism smoothly and without excessive force being required.

3. Keylock Gates (not Fortress style)

These tests shall be carried out in liaison with the Signaller or crossing keeper:

3.1 Check that with the gates open for road traffic, the keys are locked in the gate lock units.

3.2 Check the following in the signal box or gate box:

a) Mechanical Signal Boxes - The frame release lever is locked.

b) Panel Signal Boxes - The protecting signals cannot be cleared.

c) Gate Boxes - A release to the controlling signal box cannot be given.

3.3 Close the gates to road traffic and check the following:

a) The gates swing without excessive force being required.

b) The gates do not catch on the road surface during any part of their movement.

3.4 Check that the keys are not released from the lock units until the gate bolt is fully home.

3.5 Check with the keys removed, the gate bolts cannot be withdrawn.

3.6 Place the first key into the release unit in the signal/gate box and turn. Check the conditions remain as in 3.2.

3.7 Place the second key into the release unit and turn. Check that the first key is locked.

3.8 With both keys turned in the release unit check:

a) Mechanical Signal Boxes - The frame release lever is unlocked and can be reversed.

b) Panel Signal Boxes - The protecting signals can be cleared.

c) Gate Boxes - A release to the controlling signal box can be given.

3.9 Check that the keys are locked in the release unit until:

a) Mechanical Signal Boxes - The frame release lever is returned to the normal position.

b) Panel Signal Boxes - The protecting signals are returned to their most restrictive aspect.

c) Gate Boxes - The release from the controlling signal box is given back.

3.10 Remove the keys (in the correct order) from the release unit and check the conditions return to as described in 3.2.

3.11 Replace the keys in the gates and check the gate bolt can be withdrawn.

4. Fortress Key Locks

4.1 For each gate in turn:

a) Close the gate: Operate the bolt and lock to release the key.

b) Check that the key cannot be withdrawn until the bolt is in the unit and that once the key is withdrawn, the bolt cannot be released from the lock.

c) Return the key to the lock and open the gate.

4.2 For each lever fitted with a lock:

a) Check that the lever cannot be released until the key/s is/are put into the lock and turned.

b) Check that the key/s cannot be removed once the lever is moved out of the lock position.

4.3 For each solenoid lock:

a) Check that signals cannot be cleared until the key is put into the lock and turned.

b) If appropriate, check that the key/s cannot be removed once signals have been cleared for a train to approach.

5. Hand Operated Gates

Manned hand gates open across the rails, user operated hand gates open away from the rails.

5.1 Check the following on hand gate operation:

a) If provided, any equipment for calling the gatekeeper operates correctly.

b) The gates swing without excessive force being required.

c) Gates on bridleways have latches that can be operated by mounted horse riders.

d) The gates do not catch on the road surface during any part of their movement.

e) Any gate self-closing mechanism (if provided) is effective.

f) When open to road traffic, (if provided) any gate securing mechanism is effective.

END

Includes:	SD cards in a PLC unit used in EBI Gate 200 Crossing System
Excludes:	All other SD cards

GENERAL

Before any data collection is carried out, power down the EBI Gate 200 System.

The system can be irreparably damaged if the SD Card is removed whilst the system is powered up and working.

Only a SIEMENS SIMATIC memory card can be used.

Downloading the Daylog Data

1. SD Card Removal

1.1 Power down the Panel Fuse on TB2 at the top rear of the lower enclosure.

1.2 Open the SD Card Cover on PLC by pulling gently on the tab on the top right-hand corner of the cover (See Figure 1). This clicks as the cover releases.

Figure 1 – Lower Enclosure

1.3 Remove the SD Card by gently pressing the SD Card inwards and releasing it (See Figure 2). The SD Card slot is sprung-loaded, and the SD Card releases.

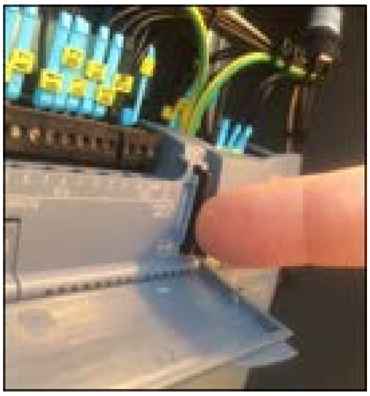

Figure 2 – Press the SD Card inwards

1.4 Downloaded the data to a laptop as described within Section 2.

NOTE: *a replacement SD card of the correct type can be inserted to allow the removed SD Card to be downloaded off site.*

1.5 Re-insert the SD Card back into the PLC. Push gently until you hear the SD Card "click" into place.

2. Copy DayLog Data

2.1 The SD Card (Figure 3) is a standard size and fits into standard SD Card readers/Slots on PC's/Laptops.

Figure 3 – SD Card

2.2 Plug the SD Card into the PC/Laptop SD Slot (Figure 4).

Figure 4 - SD Card into the PC/Laptop SD Slot

2.3 The SIMATIC MC symbol (Figure 5) appears on the desktop.

Click the icon to open.

Figure 5 – SIMATIC MC Symbol

DO NOT Delete or alter the Data or the files on the SD Card. Only copy the data.

2.4 When the SD Card is opened, there are 3 objects in the SD Card Folder (Figure 6).

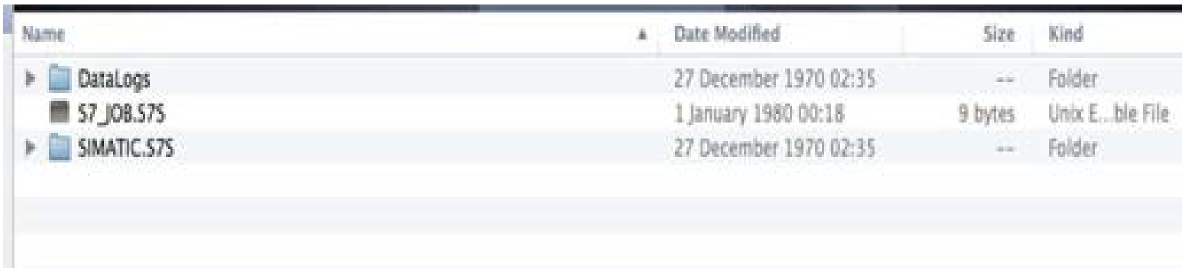

Figure 6 – SD Card Folder

2.5 Open the DataLogs folder, DO NOT open the other files or folders, the DayLog files appear (Figure 7).

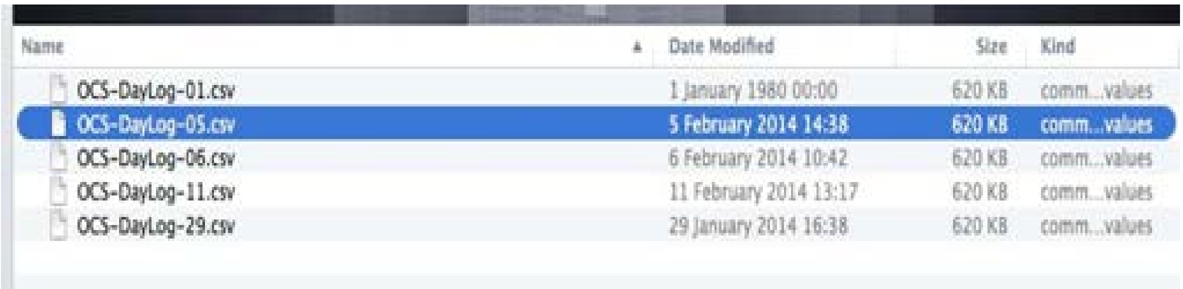

Figure 7 – DayLog Files

The DayLog files are date stamped to the day they were generated. These files are saved in a .csv format and open with Excel software.

2.6 When you open the DayLog files, they look like this (Figure 8).

NOTE: *Information on the Interpretation of the Datalog Files is covered in [NR/SMS/Appendix 09]() - General information on EBI Gate 200 Level Crossing System.*

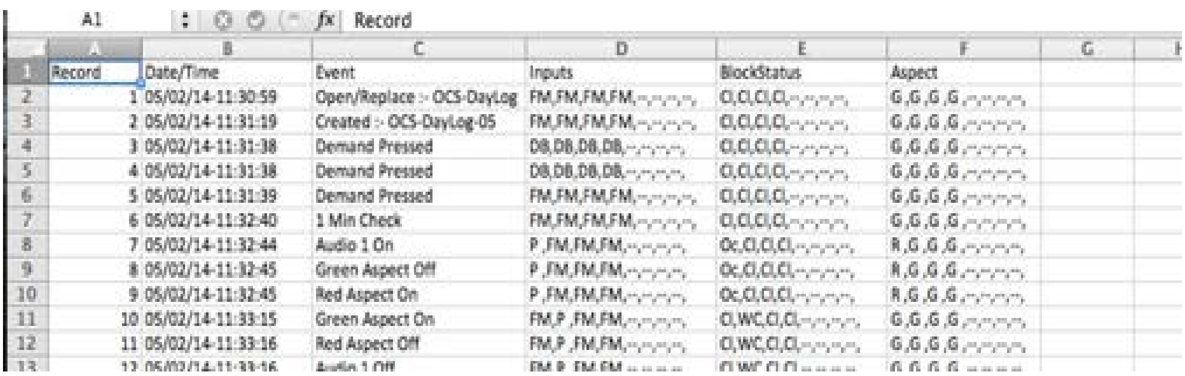

Figure 8 – Open DayLog Files

2.7 Save the file to the PC/Laptop for future reference.

2.8 Eject the SD Card from the PC/Laptop. DO NOT just pull it out of the slot, this might damage the data stored on the SD Card.

2.9 If an SD card has not already been inserted, re-insert the SD Card back into the PLC. Push gently until you hear the SD Card “click” into place.

DO NOT power up the system before replacing the SD card.

2.10 Only after the SD Card has been replaced, power up the UPS isolation fuse.

END

Includes:	AHBC controlled by a level crossing predictor
Excludes:	Any other type of AHBC, or other automatic crossing

Service A

Tests

1. **Physical Inspections**

Any obstructions or conditions likely to prove detrimental to the reliability of the level crossing system shall be dealt with immediately (if practicable) or brought to the notice of the SM(S) and dealt with as soon as possible.

The objective of this examination is to find and remove potential causes of failure and check that, as far as possible, the level crossing can function satisfactorily until the next examination.

This test requires the use of a frequency meter.

1.1 Walk through all approaches and the Island Circuit, and Check the following:

- The integrity of all tail cables and that they are securely attached to the rails as shown on the site set-up sheet.
- The integrity of all fixed and variable shunts and that they are securely attached to the rails.
- The integrity of all bonding within the Predictor approach areas.
- The integrity of cable fasteners on rails and sleepers.
- The integrity of Wideband Joint Couplers and connections.
- That there is at least two turns per foot on twisted pair wiring.
- The frequency of track voltages against the site set-up sheet in the circuit diagrams.
- For insulation deterioration and rail end burring over insulated rail joints.
- Where appropriate, the scorched earth policy is being complied with.
- For metallic or other contaminations on the surface of the rails.
- Check for rust and other contamination on the surface of the rails.
- Check the integrity of rail and clip insulations on the track with concrete or metal sleepers.
- Check the condition of the ballast and report any build-up of ballast against the rails, wet beds in the vicinity or insulated rails joints, and significant

patches of wet ballast.

2. Local Control Sequence

If the frequency of timetabled train services during the test period is such that an extended gap exists between trains on both lines, arrangements should be made for the completion of crossing sequence observations to be carried out on a subsequent visit.

2.1 Operate the LCU to the LOWER position, observe that the road lights illuminate, audible warnings operate, boom lamps illuminate, and the booms lower.

2.2 Confirm that no trains are approaching

2.3 Operate the LCU to the RAISE position, observe that the booms rise, the road lights extinguish and the audible warnings cease.

2.4 Operate the LCU to the LOWER position, allow the lowering sequence to take place and then operate the LCU to the AUTO position. Observe the booms rise, the road lights extinguish, and the audible warnings cease.

2.5 Close and lock the LCU door. Check the door cannot be locked unless the switch is in the AUTO position.

3. Automatic Control Sequence.

During the Automatic Control Sequence tests, Check that trains never reach the level crossing in less than 27 seconds from initiation of the warning sequence.

Any such occurrence should be immediately reported to your SM(S).

As trains approach, check that the loop impedance (EZ – WRSL, RX – GETS) decreases in a steady manner.

3.1 With a train approaching the crossing, Observe that the following sequence takes place:

a) If applicable on double lines that with no other train in section, all amber lights illuminate, and all audible warnings sound at the normal rate.

b) The output of the Level Crossing Predictor is not energised, and that any associated indication is not illuminated.

c) After 3 seconds the amber lights extinguish and all the red flashing road traffic light signals and any pedestrian signals commence to flash, audible warnings continue to sound.

d) After approximately 4 seconds the booms commence to lower and the boom lamps illuminate when the booms are at approximately 80° from the horizontal.

e) The booms take 6 to 8 seconds to reach the lowered position and are horizontal when fully lowered.

f) When the train arrives at the level crossing the associated Island Circuit is de- energised and that any associated indication is not illuminated.

g) The red flashing road traffic light signals and any pedestrian signals are continue to flash and the audible warnings continue to sound.

3.2 When the train has passed over the crossing, Observe the following:

a) The booms begin to rise without significant delayAfter the train has left the crossing the output of the Level Crossing Predictor is restored and that any associated indication is illuminated and the appropriate Island Circuit is restored and that any associated indication is illuminated.

b) Before the booms have reached 45° above the horizontal the red flashing road traffic lights extinguish, and the audible warning ceases.

c) After the booms have reached approximately 81° above the horizontal, the boom lights extinguish.

d) After commencing to rise, the booms reach their final position in no more than 7.5 seconds.

e) When raised, the booms are between 81° and 85° from the horizontal.

3.3 Check that the level crossing operates in accordance with the sequence in 3.1 and 3.2 when repeating these observations for a train approaching from any other direction.

4. Double Line Second Train Approaching Sequence.

4.1 With a train entering the crossing control area on line one, Observe that the sequence is the same as that detailed in 3.1

4.2 When a second train enters the crossing control area on line 2, Observe the following:

a. The booms remain lowered.

b. The road traffic lights and any pedestrian lights continue to flash and the audible warning continues at the normal rate.

4.3 When the leading end of either train passes over the crossing Check that the audible warning rate changes to the increased rate.

4.4 When the train in 4.3 has passed completely over the crossing, Observe the following:

a. The booms remain lowered.

b. The road traffic lights and any pedestrian lights continue to be flash and the audible warning continues at the increased rate.

4.5 When the second train has passed completely over the crossing Observe that the sequence is the same as that detailed in 3.2.

4.6 Where there is a suitable frequency of trains, repeat 4.1 to 4.5 for other combinations of approaching trains.

5. Indications.

5.1 Check that the correct indications are received in the monitoring signal box throughout the local control and automatic sequence tests.

Situation	Indication
Automatic control, no train approaching, or no train simulation applied	Barriers Raised
Crossing on Local Control or in failure #1	Barriers Working Barriers Failed #2
Automatic control, train approaching or train simulation applied	Barriers Working
Power Removed from LCP	Standby In Use

Table 1 – Indications

#1 Check the circuit diagrams for the contacts in the barrier proving circuit.

#2 The Barriers Failed indication occurs no more than 180 seconds after the Barriers Working indication is displayed on a single line, and no more than 240 seconds after the Barriers Working indication is displayed on a double line. The Barriers

Failed indication is accompanied by an audible warning.

Service B

Tests

These tests are for the full annual test of the crossing. NR/SMS/Part/D lists the indexes and references to the A4 format (with tick boxes) of this test for the use of the person testing the crossing

End

Includes:	MSL crossing controlled by a Level Crossing Predictor
Excludes:	Any other type of MSL, or automatic crossing

Service A

Tests

1. Physical Inspections

The objective of this examination is to find and remove potential causes of failure and check that, as far as possible, the level crossing will function satisfactorily until the next examination.

Any obstructions or conditions likely to prove detrimental to the reliability of the level crossing system shall be dealt with immediately (if practicable) or brought to the notice of the SM(S) and dealt with as soon as possible.

This test requires the use of a frequency meter.

1.1 Walk through all approaches and the Island Circuit, and Check the following:

a) The integrity of all tail cables and that they are securely attached to the rails as shown on the site set-up sheet.

b) The integrity of all fixed and variable shunts and that they are securely attached to the rails.

c) The integrity of all bonding within the Predictor approach areas.

d) The integrity of cable fasteners on rails and sleepers.

e) The integrity of Wideband Joint Couplers and connections.

f) That there is at least two turns per foot on twisted pair wiring.

g) The frequency of track voltages against the site set-up sheet in the circuit diagrams.

h) For insulation deterioration and rail end burring over insulated rail joints.

i) Where appropriate, the scorched earth policy is being complied with.

j) For metallic or other contaminations on the surface of the rails.

k) For rust and other contamination on the surface of the rails.

l) The integrity of rail and clip insulations on the track with concrete or metal sleepers.

m) The condition of the ballast and report any build up of ballast against the rails, wet beds in the vicinity or insulated rails joints, and significant patches of wet ballast.

2. Automatic Control Sequence.

2.1 During the Automatic Control Sequence tests, Check that trains never reach the level crossing in less than:

a) 20 seconds from initiation of the warning sequence on a Footpath Crossing,

b) And not less than 40 seconds on a Bridleway or User Worked Crossing.

Any such occurrence shall be immediately reported to your SM(S).

2.2 As trains approach, check that the loop impedance (EZ – WRSL, RX – GETS) decreases in a steady manner.

2.3 With a train approaching the crossing, Observe that the following sequence takes place:

a) If applicable on double lines that with no other train in section, all green lights are extinguished, all red lights illuminate and, where provided, all audible warnings sound.

b) The output of the Level Crossing Predictor is not energised, and that any associated indication is not illuminated.

c) When the train arrives at the level crossing the associated Island Circuit is de-energised and that any associated indication is not illuminated.

d) The red lights signals are illuminated and that, where provided, the audible warnings continue to sound.

2.4 After the train has passed completely over the crossing, observe that the red lights are extinguished, all green lights are illuminated and, where provided the audible warning ceases without significant delay.

2.5 Check that after the train has left the crossing the output of the Level Crossing Predictor is restored and that any associated indication is illuminated.

2.6 Check that the appropriate Island Circuit is restored and that any associated indication is illuminated.

2.7 Check that the level crossing operates in accordance with the sequence in 2.2 to 2.6 when repeating these observations for a train approaching from any other direction.

3. Double Line Second Train Approaching Sequence.

3.1 With a train entering the crossing control area on line one, observe that the sequence is the same as that detailed in 2.1

3.2 When a second train enters the crossing control area on the line 2, Observe the following:

a) The red lights remain illuminated.

b) Where provided, the audible warning continues at the normal rate

3.3 When the leading end of either train passes over the crossing Check where provided that the audible warning rate changes to the increased rate.

3.4 When the train in 3.3 has passed completely over the crossing, Observe the following:

a) The red lights continue to be illuminated.

b) Where provided, the audible warning continues at the increased rate.

3.5 Observe the second train passing completely over the crossing and observe that the sequence is the same as that detailed in 2.2 to 2.6.

3.6 Where there is a suitable frequency of trains, repeat steps 3.1 to 3.4 for other combinations of approaching trains.

Service B

Tests

These tests are for the full annual test of the crossing. NR/SMS/Part/D lists the indexes and references to the A4 format (with tick boxes) of this test for the use of the person testing the crossing.

End

Includes:	Systems fitted with **"both"** IMC & ACB Boards
Excludes:	Systems fitted with **"only"** IMC Boards

General

Before work is undertaken that affects the normal operation of the level crossing system the Signaller shall be informed. Normally a possession of the equipment or a no train period is required.

The tests in sections 1 to 3 are required when wheel sensors are replaced or removed and re-fitted.

1. Frauscher RSR123 Wheel Sensor Test (System Adjustment)

1.1 Before starting work the system shall be powered down by the removal of the main supply fuse in the master post.

1.2 Disconnect the wheel sensor cable in the trackside connection box (GAK unit).

1.3 Connect a multimeter set on 0-1V DC to the AMB001 test box socket (See Figure 1). Press the toggle switch on AMB001 to the battery symbol. The multimeter reading shall be > 0.75 V, if not the battery of the test box AMB001 needs replacing.

Figure 1 – AMB001 Test Box

1.4 Sensor System 1. Connect wire 1 (brown) to the red connector and wire 2 (yellow) to the black connector (See Figure 2). The adjustment procedure starts automatically. After approximately 10 seconds the multimeter shall show a value between 0.49 V and 0.515 V.

Figure 2 - AMB001 Test Box Connected

1.5 If the measurements are outside of this range then try re-aligning the head to the centre of the tolerances, reference NR/SMS/PartC/AX40 (Frauscher Advanced Axle Counter) - Period Task 3. If this is unsuccessful then the wheel sensor shall be replaced.

1.6 Within 50 seconds of test step 1.3 place the testing plate PB200 over sensor system 1 (see Figure 3) and check that the multimeter value is between 330mV and 375mV.

Figure 3 – PB200 Over Sys1

1.7 If the measurements are outside of this range then try re-aligning the head to the centre of the tolerances, reference NR/SMS/PartC/AX40 (Frauscher Advanced Axle Counter) - Periodic Task 3. If this is unsuccessful then the wheel sensor shall be replaced.

1.8 Reconnect the wires to the trackside connection box to wiring diagrams.

1.9 Sensor System 2. Connect wire 3 (green) to the red connector and wire 4 (white) to the black connector. The adjustment procedure starts automatically. After approximately 10 seconds the multimeter shall show a value between 0.49 V and 0.515 V.

1.10 If the measurements are outside of this range then try re-aligning the head to the centre of the tolerances, reference NR/SMS/PartC/AX40 (Frauscher Advanced Axle Counter) - Periodic Task 3. If this is unsuccessful then the wheel sensor shall be replaced.

1.11 Within 50 seconds of test step 1.8 place the testing plate PB200 over sensor system 2 (see Figure 4) and check that the multimeter value is between 330mV and 375mV.

Figure 4 - PB200 Over Sys2

1.12 If the measurements are outside of this range then try re-aligning the head to the centre of the tolerances, reference NR/SMS/PartC/AX40 (Frauscher Advanced Axle Counter) - Periodic Task. If this is unsuccessful then the wheel sensor shall be replaced.

1.13 Power up the axle counting system, as described in Section 2 of this document.

1.14 Undertake the wheel sensor detection capability test, as described in Sections 4 & 5 of this document

2. Level Crossing System Power Up

2.1 At the master post replace the main supply fuse to energise the system.

2.2 Check that the Green “DC Okay” LED is illuminated on the 24vDC power supply.

2.3 Check the two 5V LEDs (green) on the ACB board illuminate and observe that the display initially shows LRNO for approximately 5 seconds.

2.4 Observe the ACB display changes to flashing **** for approximately 10 seconds indicating system initialisation. After 10 seconds the ACB display changes to an alternating display of -109 / -209. This indicates that the system is now waiting for the axle counter section to be occupied and cleared.

2.5 Observe the two green PWR LEDs on the IMC evaluator board are illuminated.

2.6 To reset the ACB displays to 0 undertake one of the options, as described in section 3 of this document.

3. Block Section Test and Reset Sequence

3.1 To test and reset the ACB displays to 0, undertake one of the options 3.3 or 3.4.

3.2 To reset all Block Sections simultaneously undertake option 3.5.

3.3 Observe the passage of a train on each line.

a) Observe the number of axles counted in and the ACB Occupied LED (red) is lit.

b) Check all the axles are counted out of the section and the ACB display count shows 0.

c) Check the Occupied LED (red) is extinguished.

3.4 Activate the axle counter heads in sequence using the test plate PB200 over each head for each line.

a) In the normal direction of travel slowly sweep test plate PB200 over a Strike-in wheel sensor. This simulates one axle in block section.

b) check the section ACB display shows 1 and the Occupied LED (red) is lit.

c) In the normal direction of travel slowly sweep the test plate over the section Strike-out head.

d) Check that the ACB for block section 1 shows 0 and the Occupied LED for the section is extinguished.

e) Check the ACB for block section 2 shows 1 and the Occupied LED is lit.

f) In the normal direction of travel slowly sweep the test plate over the Strike-out head for the block section 2.

g) Check that the section ACB display shows 0 and the Occupied LED (red) is extinguished.

3.5 Operate the reset switch.

3.6 The successful completion of either 3.3, 3.4 or 3.5 initialises the system, ready for service.

3.7 Failure of any of the above tests should be reported as corrective maintenance.

4. Wheel Sensor Test for NDI and NDO heads (Detection Capability)

4.1 Identify the Evaluation Board (IMC) related to the axle counter sensor to be tested and check the section is indicating clear. The IMC Board should only have the two green power LEDs lit (Figure 5) and the associated ACB display shows 0 (Figure 6).

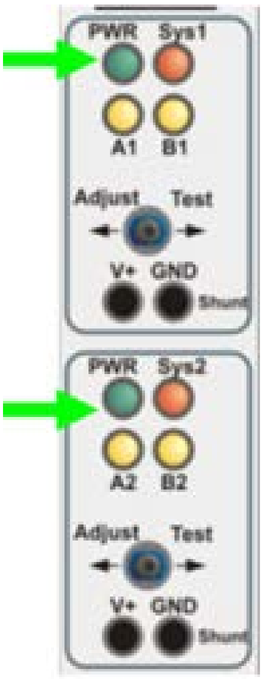

Figure 5 - IMC Board

Figure 6 – ACB Board

4.2 Place the PB200 testing plate on the railhead, on the approach side of the axle counter wheel sensor, for a train moving in the normal direction. This is the start position (Figure 7).

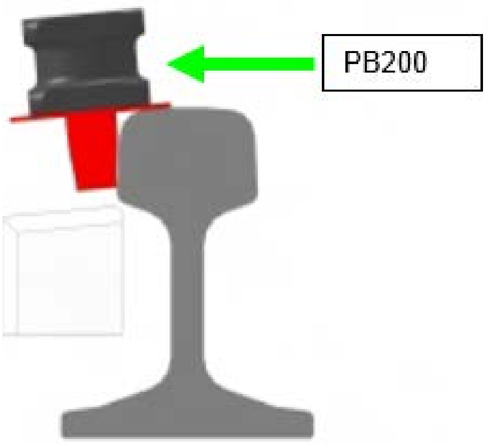

Figure 5 - PB200

4.3 Move (slide) the PB200 slowly in the normal direction of travel and stop over the first wheel sensor (Figure 8).

4.4 Check the LED indications SYS1 and B1 are illuminated (Figure 9) and the ACB display shows <00> (Figure 13). Whilst testing the NDO, BS1/BS3 ACB shows an error code and BS2/BS4 shows as per Figure 10.

Figure 6 – PB200 Over Sys1

Figure 7 – IMC Board

Figure 8 – ACB Board

4.5 Move (slide) the PB200 slowly in normal direction of travel and stop in between the two wheel sensors systems (Figure 11).

4.6 Check the LED indications SYS1, SYS2 and B1, B2 are illuminated (Figure 12).

Figure 11 – PB200 Mid Position

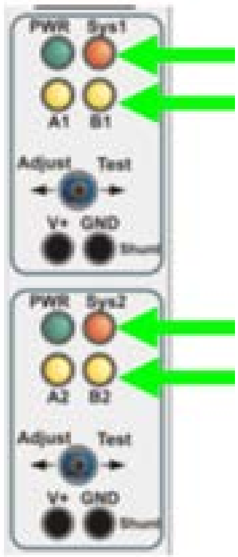

Figure 12 – IMC Board

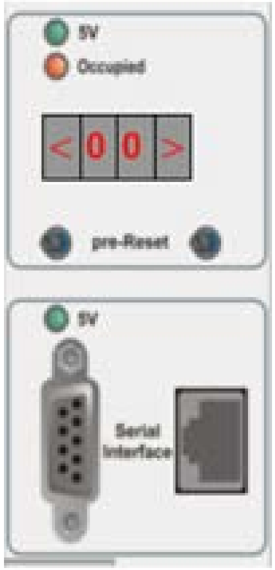

Figure 13 – ABC Board

4.7 Move (slide) the PB200 slowly in normal direction of travel and stop over the second wheel sensor (Figure 14).

4.8 Check the LED indications SYS1 and B1 have extinguished and the LED indications SYS2 and B2 remain illuminated (Figure 15).

Figure 14 – PB200 Over Sys2

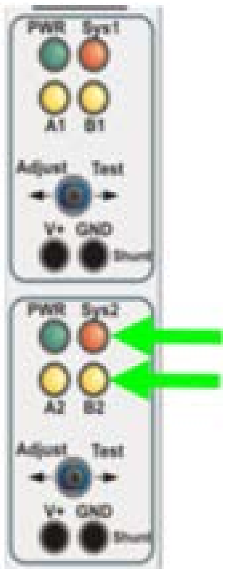

Figure 15 – IMC Board

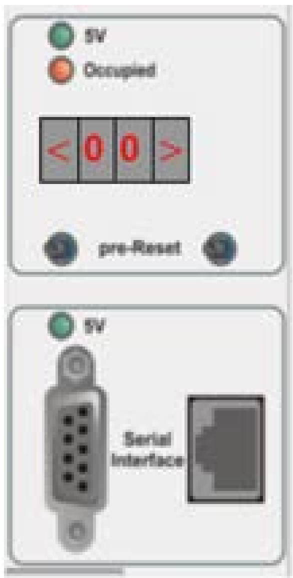

Figure 16 – ACB Board

4.9 At the end of the simulation, when the PB200 testing plate has passed beyond the sensor check the LED indications SYS2 and B2 have extinguished on the IMC Board leaving the two PWR indications illuminated, this indicates that the head/sensor has sensed a complete sweep (Figure 17). Check the ACB Display now indicates a single axle count (Figure 18). Whilst testing the NDO, BS1/BS3 ACB shows an error code and BS2/BS4 ACB displays a count of one.

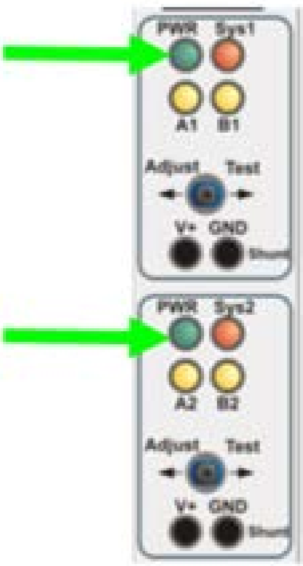

Figure 17 – IMC Board

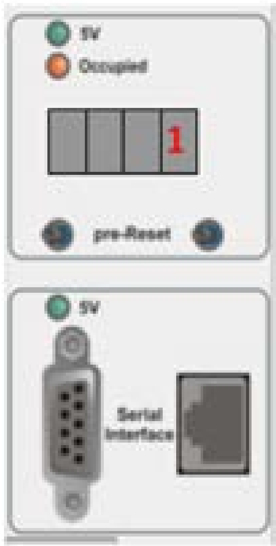

Figure 18 – ACB Board

4.10 The PB200 shall now be traversed over the axle counter sensors in the reverse direction to clear the section / track. When testing the NDO, BS2/BS4 ACB resets to zero and the BS1/BS3 ACB displays an error code.

Figures 8, 11 and 14 illustrate the PB200 moving over a sensor mounted on the cess rail, if the sensor were fitted on the 10ft rail then the direction of travel of the PB200 would be reversed.

4.11 If a wheel sensor detection test is carried out in isolation the on an NDO it is likely to have caused BS1/3 to fail. To clear this issue the system shall be reset.

5. Wheel Sensor Test for XDI heads (Detection Capability)

5.1 Identify the Evaluation Board (IMC) related to the axle counter sensor to be tested and check the section is indicating clear. The IMC Board should only have the two green power LEDs lit (Figure 19) and the associated ACB display shows 0 (Figure20).

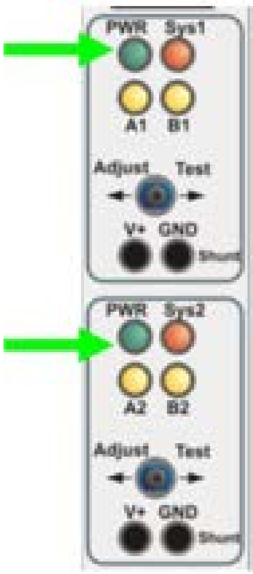

Figure 9 – IMC Board

Figure 10 – ACB Board

5.2 Place the PB200 testing plate on the railhead, on the approach side of the axle counter wheel sensor, for a train moving in the wrong direction. This is the start position (Figure 7).

5.3 Move (slide) the PB200 slowly in wrong direction of travel and stop over the first wheel sensor (Figure 21).

5.4 Check the LED indications SYS2 and B2 are illuminated (Figure 22) and the ACB display shows <00> (Figure 23).

Figure 21 – PB200 Over Sys2

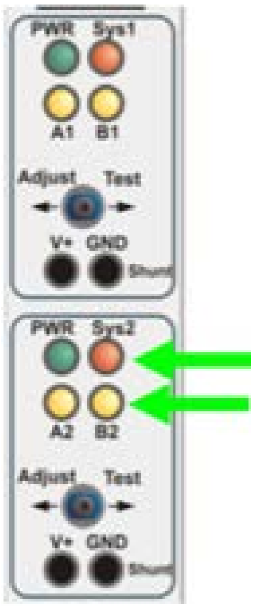

Figure 11 - IMC Board

Figure 23 – ACB Board

5.5 Move (slide) the PB200 slowly in wrong direction of travel and stop in between the two wheel sensors systems (Figure 24).

5.6 Check the LED indications SYS1, SYS2 and B1, B2 are illuminated (Figure 25).

Figure 24 – PB200 Mid Position

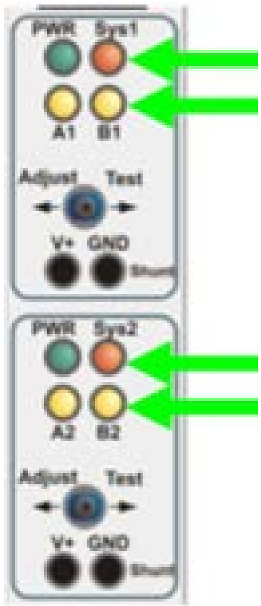

Figure 12 - IMC Board

Figure 26 – ACB Board

5.7 Move (slide) the PB200 slowly in normal direction of travel stop over the second wheel sensor (Figure 27).

5.8 Check the LED indications SYS1 and B1 have extinguished and the LED indications SYS2 and B2 remain illuminated (Figure 28).

Figure 27 – PB200 Over Sys1

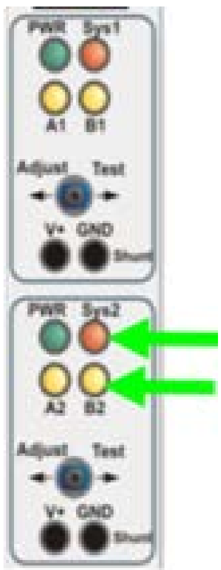

Figure 28 – IMC Board

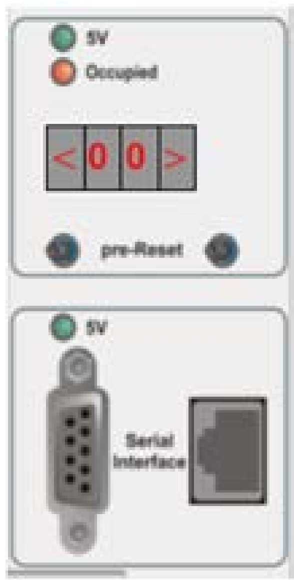

Figure 13 – ACB Board

5.9 At the end of the simulation, when the PB200 testing plate has passed beyond the sensor check the LED indications SYS2 and B2 have extinguished on the IMC Board leaving the two PWR indications illuminated, this indicates that the head/sensor has sensed a complete sweep (Figure 30). Check the ACB Display now indicates a single axle count (Figure 31).

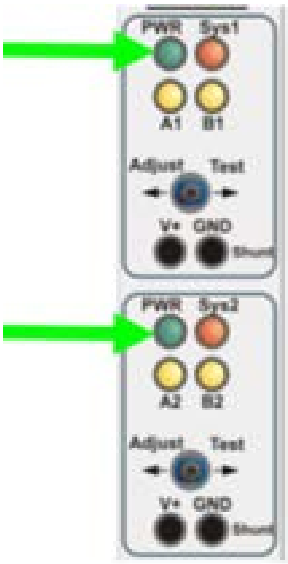

Figure 30 – IMC Board

Figure 31 – ACB Board

5.10 The PB200 shall now be traversed over the axle counter sensors in the reverse direction to clear the section/track.

5.11 If a wheel sensor detection test is carried out in isolation the on a single unit it is likely to have caused the associated block section to fail. To clear this issue the system shall be reset using the Test/Reset facility.

Figures 21, 24 and 27 shows the PB20 moving over a sensor mounted on the cess rail, if the sensor were fitted on the 10ft rail then the direction of travel of the PB200 would be reversed.

6. Functional Task – Operational Sequence Test

6.1 Check no train enters the level crossing strike in area from any direction for the duration of test.

6.2 Push the On-Demand button on one of the units if applicable and observe the green lights illuminate in both units. Commence timing the lights and check that the green lights are extinguished after 5 minutes.

6.3 Press the on demand button (if provided). Simulate a train occupying an entrance section by entering one axle using the test switches on a Strike-in evaluator board (IMC). Observe the green lights in both units are extinguished; the red lights illuminate and check the audible warnings sound. Observe the entrance block section ACB display shows 1 and the ACB Occupied LED (red) is illuminated.

6.4 Simulate a train arriving at the crossing and exiting the entrance section by entering one axle using the test switches on the Strike-out evaluator board (IMC) to clear the axle counter section. Observe the crossing lights change from red to green and Check the audible warning ceases. Observe the entrance section ACB display shows 0 and the ACB Occupied LED (red) is extinguished.

Reference should be made to local documentation as the toggle switch sequence is related to the layout of the sensor heads.

Observe the exit block section ACB display shows 1 and the ACB Occupied LED (red) is illuminated.

6.5 To complete the sequence, simulate the train leaving the exit block section. Observe that the ACB display for the exit block section shows 0 and the ACB Occupied LED (red) is extinguished.

6.6 Repeat 6.3 to 6.5 for all other lines (normal direction strike-in), there is no need to wait for 5 minutes to elapse between tests.

7. Double Lines Second Train Approaching Sequence Test

7.1 Push the On-Demand button (if applicable/fitted) on one of the posts and observe the green lights illuminate in both units.

7.2 Simulate a train occupying an entrance section on line 1. Enter two axles using the test switches on a Strike-in evaluator board (IMC) for line 1. Observe the green lights in both units are extinguished the red lights illuminate and check the audible warnings sound. Observe the entrance section ACB display shows 2.

Reference should be made to local documentation as the toggle switch sequence is related to the layout of the sensor heads.

7.3 Simulate a second train occupying an entrance section on line 2. Enter two axles using the test switches on a Strike-in evaluator board (IMC) for line 2. Check the lights continue to show red. Observe the entrance section ACB display for the second line shows 2 and the ACB Occupied LED (red) is illuminated.

7.4 Simulate the train on line 1 arriving at the crossing by entering one axle using the test switches on the entrance section Strike-out evaluator board (IMC) for line 1. Observe the red lights remain illuminated and check the audible warning changes to the increased ATC rate. Observe the entrance section ACB display shows 1.

7.5 Simulate the train on line 1 exiting the entrance section by entering a second axle using the test switches on the Strike-out evaluator board (IMC) for line 1. Observe that the light units continue to show a red light and check the increased audible warning rate continues. Observe the entrance and exit section ACB displays shows 0 and the ACB Occupied LED (red) is extinguished.

7.6 Simulate the train on line 2 arriving and exiting the entrance section by entering two axles using the test switches on the entrance section Strike-out evaluator board (IMC) for line 2. Observe that the red lights are extinguished; the green lights are illuminated and check the audible warning ceases. Observe the entrance section ACB display for the second line shows 0 and the ACB Occupied LED (red) is extinguished.

7.7 At this stage the exit section in the direction of travel, for both lines are occupied. To complete the sequence, simulate the train leaving the exit block section on both lines. Observe that the ACB display for the exit block section shows 0 and the ACB Occupied LED (red) is extinguished.

7.8 Repeat 7.1 to 7.7 for all other normal direction ATC permutations.

END

Includes:	All types of Automatic Open Crossing Locally Monitored plus Barriers (AOCL+B)
Excludes:	All other types of Crossing

Liaise with the Signaller before any tests are carried out

Check in the crossing control tables for any special controls that affect the automatic control sequence.

Where the word EXIT occurs, the strike out treadle shall be operated.

On single lines or where bi-directional controls exist, the leaving track circuit shall also be operated.

Where directional proving controls exists the bi-directional strike out treadle shall also be operated in the correct sequence.

The following abbreviations are used in this service:

- DRL: Driver's Red Light.
- DWL: Driver's White Light

SERVICE A

1. Local Control Sequence (If Provided)

1.1 Operate the Local Control Unit (LCU) to the on/lower/hand position: Observe road lights illuminate, audible warnings operate, crossing headlights illuminate and the barriers lower. Check the DWLs do not illuminate

1.2 Confirm that no trains are approaching before proceeding.

1.3 Operate the LCU to the off position. Observe the barriers rise, the road lights extinguish, the crossing headlights extinguish and audible warnings cease.

1.4 Operate the LCU to the on/lower/hand position, allow the lowering sequence to take place and then operate the LCU switch to the auto position, close and lock the LCU door.

1.5 Observe the barriers rise, the road lights extinguish, and audible warnings cease.

1.6 Check that all DRL are flashing.

1.7 Check the LCU door cannot be locked unless the switch is in the auto position.

1.8 Check that the DRL is flashing for all signalled directions.

2. Automatic Control Sequence

2.1 Observe, with no train approaching, all DRLs are flashing.

2.2 Simulate an approaching train by shunting a controlling track circuit. Observe the following:

a) On double lines 10 seconds elapse before the crossing sequence commences. On single lines the sequence starts immediately.

b) All the amber road signals illuminate, and the audible warnings commence concurrently (Yodalarms at normal warbling rate).

c) After 3 seconds all the amber signals extinguish, and all the red road signals and any pedestrian lights start to flash.

d) The crossing headlights illuminate the crossing at the same time the red road lights commence to flash.

e) After approximately a further 4 seconds the barriers commence to lower and the boom lamps illuminate. Check the sighting of the boom lamps.

f) As the barriers commence to lower the driver's red light extinguishes and the DWL commences to flash for the direction where the train simulation was applied. The DRL continues for the opposing directions.

g) The barriers take 6 to 8 seconds to reach the fully lowered position.

h) The crossing headlights, red road lights and any pedestrian lights continue to be illuminated and audible warnings continue to sound.

2.3 Operate the exit function and remove the train simulation. Observe the following:

a) The barriers begin to rise.

b) The DWL for the direction where the simulation was applied extinguishes and the DRL (if provided) commences to flash.

c) The red road lights and crossing headlights extinguish and the audible warnings cease when the barriers have reached approximately 45° from the horizontal.

d) The boom lights extinguish when the barriers have reached approximately 81° from the horizontal.

e) The barriers do not take more than 7 seconds to reach the fully raised position of between 81° and 85° from the horizontal.

2.4 Repeat steps 2.2 and 2.3 for the opposite direction on a single line and the other direction on double lines.

3. Double Lines Second Train Approaching Sequence

3.1 Simulate a train striking in on line one as per 2.2

3.2 Simulate a second train striking in on line two. Observe the following:

a) The barriers remain lowered.

b) The road lights and any pedestrian lights continue to flash.

c) The audible warning rate continues at the normal rate.

d) The crossing headlights continue to illuminate.

3.3 Operate the exit function and remove the simulation on line one. Observe the following:

a) The barriers remain lowered.

b) The road lights and any pedestrian lights continue to flash.

c) The audible warning rate changes to the increased rate.

d) The crossing headlights continue to illuminate.

e) The DWL for the direction of the simulation on line one extinguishes and the DRL commences to flash.

f) The DWL for the simulation on line two continues to flash.

3.4 Operate the exit function and remove the simulation on line two. Observe that the sequence is the same as described in 2.3.

3.5 Repeat steps 3.1 to 3.4 for a train striking in on line two first and a second train striking in on line one.

3.6 Where possible, observe the correct crossing sequence during passage of a train(s).

SERVICE B

These tests are for the full annual test of the crossing. NR/SMS/PartD/Index lists the indexes and references to the A4 format (with tick boxes) of these tests for the use of the person testing the crossing.

APPENDIX A - Indications

Table 1 lists the driver indications displayed throughout a local control and automatic sequence:

<table>
<tr><th>Situation</th><th>Indication</th></tr>
<tr><td>Automatic control, no train approaching, or no train simulation applied</td><td rowspan="2">DRL Flashing
DWL Extinguished</td></tr>
<tr><td>Crossing on operating on Local Control</td></tr>
<tr><td>Automatic control, train approaching, or train simulation applied, barriers started to lower</td><td>DRL Extinguished
DWL Flashing</td></tr>
<tr><td>Barriers lowered by train simulation, DWL operating, any DWL proving contact broken, power off. ✱</td><td>DRL Flashing
DWL Extinguished</td></tr>
</table>

Table 1 – Driver Indications

The DWL should only operate for the direction in which the train is approaching, or the train simulation has been applied.

The DRL should be operating for all other directions

✱ Check the diagrams for the contacts in the DWL control circuit (this includes the (PO)PR function).

END

Do not enter the potential entrapment zone whilst the gate is in operation.

This includes the space between the gate, when open, and any obstruction such as fences, wall and landscaping.

1. Before commencing any adjustment

1.1 Check the gate is properly installed and all nuts are tight.

1.2 Check the top gate rail is horizontal.

1.3 Check the gate swings feely in both directions.

1.4 Check the gate engages and the solenoids lock without binding.

1.5 Check the solenoids sit in the centre of the gate latch jaws.

2. Limit Switch Adjustment

The open and closed limits of the actuator arm may need to be adjusted to guarantee flush fitting of the gate into the solenoid locks when the gate is fully open and fully closed.

The limit switches set the point at which the actuator stops driving.

For testing / adjustment purposes you may find it easier to release the actuator and turn it upside down to access the limit switch adjustment screws which are located on the underside of the actuator unit.

Once adjustments are completed flip the actuator back to the correct final installation position.

2.1 The limit switch adjustments are located on the bottom of the actuator (See Figures 1 and 2):

Figure 1 - Location of limit switches

Figure 2 - Close up

2.2 Remove the dust plug to make adjustments. Only use a small flat blade manual screwdriver.

2.3 Each gate should be tested individually. Disable gate 2 (See Figure 3) by turning to dipswitch SW 4 to the off position.

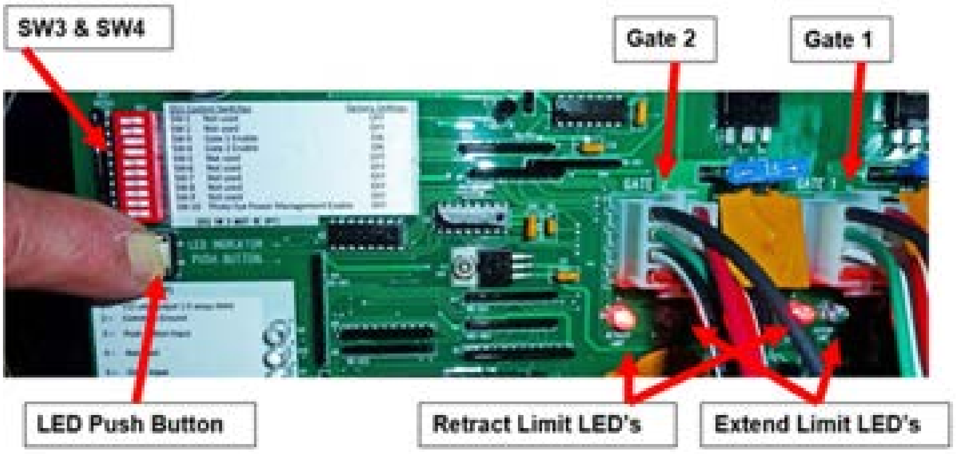

Figure 3 – NR Control Board

Closed Gate Adjustment

2.4 Operate gate 1 to the fully closed position and check it is latched. Press the LED indicator button. This should cause the extend limit LED under gate 1 to illuminate. (if the LED illuminates move to 2.9).

2.5 If the LED fails to illuminate or illuminates before travel is completed, adjust the limit switch to extend or reduce length of the actuators travel.

2.6 To extend (increase) gate travel towards the closure position turn the extend length adjustment screw clockwise. As indicated in red in Figure 4.

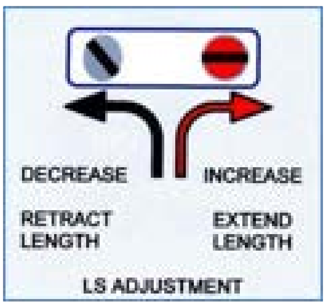

Figure 4 – Extend

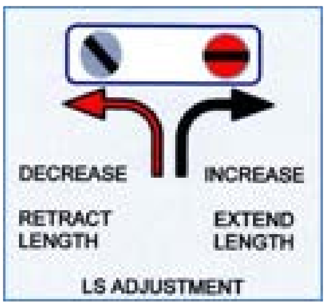

Figure 5 - Retrack

2.7 To reduce (decrease) gate travel towards the closure position turn the extend length adjustment screw counter clockwise. As indicated in red in Figure 5.

2.8 When the actuator is correctly adjusted the extend limit LED illuminates.

Open Gate Adjustment

2.9 Operate gate 1 to the open position and press the LED indicator button this should cause the retract limit LED under gate 1 to illuminate. (if the LED illuminates move to 2.14)

2.10 If the LED fails to illuminate or illuminates before travel is completed, the limit switch requires adjusting to extend or reduce length of the actuators travel.

2.11 To extend (increase) gate travel towards the open position turn the retract length adjustment screw clockwise. As indicated in red in Figure 6.

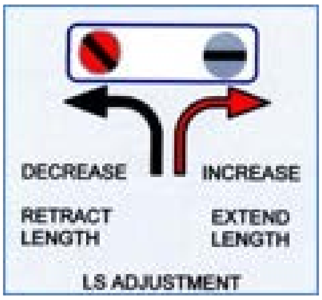

Figure 6 – Extend

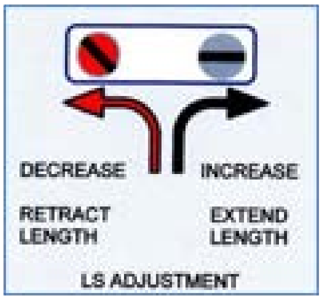

Figure 7 - Retract

2.12 To reduce (decrease) gate travel towards the open position turn the retract length adjustment screw counter clockwise. As indicated in red in Figure 7.

2.13 When the actuator is correctly adjusted the retract limit LED illuminates.

2.14 Replace the dust covers.

Remember to return the actuator to it correct position if you carried out the adjustment with the unit upside down.

3. Gate Reaction Test

3.1 Identify which gate is gate 1 and which is gate 2.

As a rule, gate 1 will be closest to the control panel and is deemed the Master with the gate across the track designated gate 2 and deemed the Slave.

3.2 Attach the 300mm extension spacer to the Closing Force Tester and Check the “ready for measurement” indication is showing (see Figure 8).

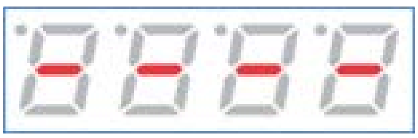

Figure 8 – Ready Indication

3.3 Open the Gate fully using the green button or the open/close button on the Control Board.

3.4 Press the Close gate button.

3.5 As the gate closes place the Closing Force Tester between the gate and the “Closed” post so the closing gate applies force to the pressure plate (See Figure 9).

Care should be taken to avoid crushing injuries and the correct PPE should be worn including gloves.

Figure 9 - Force tester in position

3.6 Check and record the reaction time recording the results on approved record card

If you are unsure of how to interpret the indications displayed on the “Closing Force Tester” then you should refer to Appendix A.

The reaction time of the gate shall be less than 0.75 seconds. If the response time exceeds this than the current sensor should be adjusted to lower the reaction time to below 0.75 seconds.

3.7 Report any failure to meet the required standard to your SM(S).

4. Current Sensor Adjustment

If any adjustment is made to a Current Sensor it is a requirement that you carry out a Gate Reaction Test before returning the gate into service. Check you have a serviceable tester before commencing any adjustment.

4.1 To carry out the adjustment you shall identify the correct current sensor potentiometer. These are found on the top edge of the Control Board and are marked as Gate 1 and Gate 2 (circled in Figure 10), one for each gate.

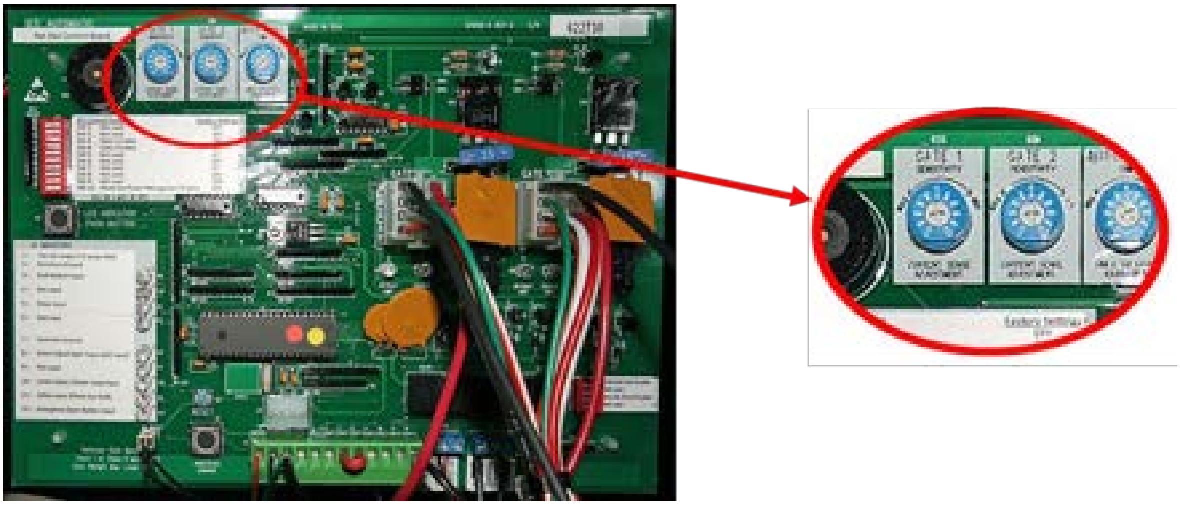

Figure 10 – NR Control Board

4.2 Using a small electrical screwdriver gently adjust the Current Sensor Potentiometer:

- To increase the Force pushing the gate you should adjust anticlockwise.
- To decrease the Force pushing the gate you should adjust clockwise.

4.3 After each adjustment the gate action time shall be rechecked using clauses 3.2 to 3.6.

The gate shall not be left to operate in automatic mode in the event of non-compliance with reaction time test.

APPENDIX A - Closing Force Tester

<u>Interpreting the outputs from the Closing Force Tester</u>

The Closing force Tester produces a series of five readings for completeness. All five are explained below. However only the second and fifth readings are recorded on the record card as explained in Clause's 2 and 5.

1. **The first indication:** This shows the closing force in Nm and is shown as a full number. This can be read directly from the unit when the force has been released.

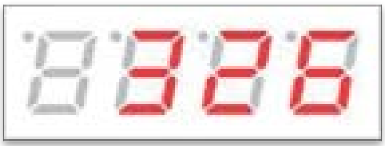

Figure 11 – Closing Force

The example in Figure 11 shows 326 N.

2. **The second indication:** In addition to the closing force reading. When the second display segment from the left flashes this indicates the dynamic time exceeded 0.75ms.

Figure 12 – Display Segment 2

3. **The third indication:** In addition to the closing force reading. When the third display segment from the left is flashing this indicates the force value exceeded 25 N at the end of the 5 second measurement period.

Figure 13 – Closing Force < 25Nm

4. **The fourth indication:** In addition to the closing force reading. When the third and fourth display segments from the left are both flashing this indicates the force value exceeded 80 N at the end of the 5 second measurement period.

Figure 14 – Closing Force < 80Nm

5. **The fifth indication:** If clause 2 has indicated a measurement in excess of 0.75 seconds then the control button on the Force Tester should be pressed once. The display shows actual dynamic time in milliseconds and this should be entered on to the record card.

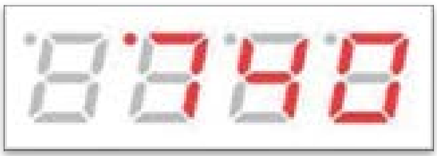

Figure 15 – Dynamic Time

The example in Figure 15 shows 740ms.

6. **The sixth Indication:** If clause 3 has indicated a measurement in excess of 25 Newtons then the control button on the Force Tester can be pressed twice. The display shows actual force value in Newton's.

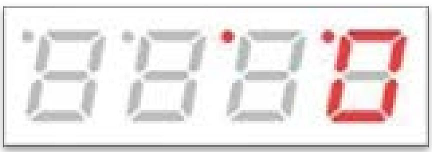

Figure 16 – Actual Force in Newton

The example in Figure 16 shows Zero Newtons.

Pressing the control button returns the user to the initial readings. The tester can be turned off by pressing and holding the button in for 2 seconds. After 5 minutes of inactivity the device powers down.

END

Includes:	Servosafe 7788, 7788R, 7789, 7789R, 8889, 8889R
Excludes:	Servotrim 9909

The tasks in these tests can be carried out by other teams or equipment specialists.

SERVOSAFE SERIES

Previously the alarm levels were checked by using the servo pen recorder. This is no longer possible due to no spares available to enable repair. Also, the pen recorder paper is now obsolete.

To check that the DPU is sending out alarms at the correct level the system has to be fully powered and the transmission link to the Signal Box disconnected (prevents alarms being transmitted whilst the unit is set up).

Connect telephone 'ear piece' with connections to R1 & R2 alarm transmitters whilst the alarm levels are being set.

Once alarms are triggered they should be heard as 'beeps'.

Once the alarm levels are set, the transmission can be turned off, links reconnected, and signaller informed prior to when transmission switched back on.

1. Locator Tests

Inform the Signaller that routine tests are being carried out. Carry out test between trains.

These tests refer to the signal box end of the equipment.

1.1 Switch OFF the 110Vac power supply and check that the system failure alarm operates (15 to 40 seconds). Restore the 110Vac power supply.

1.2 Operate Normal/Failure switch to Failure and check system failure alarm operates. Restore the Normal/Failure switch to Normal.

1.3 Certain Ex BR-WR sites only

a) Remove signal input plug and check system failure alarm operates.

b) Cancel system failure alarm by operating Normal/Failure switch to Failure.

c) Replace signal input plug and check system failure alarm operates.

d) Cancel system failure alarm by operating Normal/Failure switch to Normal.

1.4 Operate the locator reset button and observe that total alarms and axle number displays show zero.

NOTE: *For the following tasks, use the test buttons on the back of the locator:*

- TEST RL 2 (R/H alarm)
- TEST RL 1 (L/H Alarm)
- TEST WHEEL COUNT

1.5 Operate test wheel count push button twelve times.

1.6 Check that 12 is displayed in the axle number counter.

1.7 Check that total alarms remains zero.

1.8 Wait 30 seconds then operate test wheel count button once.

1.9 Observe that the axle number counter resets to 001.

1.10 Enter nine alarms, by using the TEST RL 1 and TEST RL 2 test buttons, interspersed by test wheel counts.

1.11 Check that the hot axle box alarm sounds intermittently.

1.12 Cancel the hot axle box alarm by operating the audible alarms reset button.

1.13 Check that the hot axle box indications appear under the first and last digits in the axle number display.

1.14 Check the results in the total alarms display and axle number display by use of the display selector switch.

1.15 Operate the locator reset button.

2. Calibration Tests

2.1 Make arrangements with the Signaller to enable the apparatus to be disconnected.

2.2 Switch OFF the carrier system and switch the signal box locator to FAILURE.

Calibration Temperature

2.3 Place the thermometer in the shade adjacent to the Scanners.

2.4 Switch the function simulator power and gate switches to the OFF position.

2.5 Connect the function simulator by its cable to the data processing unit and switch the function simulator power switch to the ON position.

Pedestal Pulse

2.6 On the test panel select DIR 1 and RAIL 1 and set the test panel pulse amplitude control to minimum.

NOTE: *The test panel deflection meter should display pedestal pulses of approximately 1.5mm amplitude.*

2.7 Check that the pedestal pulse amplitudes are constant, and no spurious alarms are produced.

2.8 Adjust, if necessary, RAIL 1 Pulse Processor PED ADJ control whilst observing the test panel deflection meter.

2.9 Select RAIL 2 on the test panel and repeat items 2.3 and 2.4. Adjust, if necessary, RAIL 2 pulse processor PED ADJ control.

2.10 Reset the test panel and allow the integrity test to complete.

Absolute Alarm Check (A.M.A. Right Hand Servolarm Unit)

2.11 Remove the fuse on the differential alarm unit. (A.M.D. Left-hand Servolarm Unit).

2.12 On the test panel select DIR 1 and RAIL 1.

2.13 Set the test panel test pulse amplitude control to give 15.5mm reading on the deflection meter.

2.14 On the absolute alarm unit (A.M.A. Right-hand Servolarm Unit), adjust alarm level RAIL 1 potentiometer until the alarm triggers so that there is an intermittent miss in triggering.

2.15 On the test panel increase the test pulse amplitude control to 16mm and check that triggering always occurs. Decrease the test pulse amplitude control to 15mm and check that triggering does not occur.

2.16 On the test panel select RAIL 2 and repeat items 2.9 to 2.12. Adjust the absolute alarm level RAIL 2 potentiometer.

2.17 On the differential alarm unit (A.M.D Left-hand Servolarm unit) restore the fuse.

2.18 Set the test panel pulse amplitude control to minimum.

Differential Alarm Check (A.M.D. Left hand Servolarm Unit).

2.19 On the test panel select RAIL 1.

2.20 Remove the absolute alarm fuse. Set the test pulse amplitude control to give 9.5mm reading on the deflection meter.

2.21 On the differential alarm unit (A.M.D. Left hand Servolarm Unit) adjust alarm level RAIL 1 potentiometer until the alarm triggers so that there is an occasional missing triggering.

2.22 On the test panel increase the test pulse amplitude control to 10mm. Check that triggering always occurs. Decrease the test pulse amplitude control to 9mm. Check that triggering does not occur.

2.23 On the test panel select RAIL 2 and repeat items 2.17 to 2.19. Adjust the Differential Alarm Unit (A.M.D. Left hand Servolarm Unit) Alarm Level RAIL 2 potentiometer. Re-fit the absolute alarm fuse.

2.24 On the test panel set the test pulse amplitude control to minimum. Reset the test panel and allow the integrity test to complete.

Pulse Processor Gain

2.25 Place the function simulator on the step of the RAIL 1 Scanner. For the 7788R system, use the saddle fixture.

2.26 Note the ambient temperature. On the function simulator adjust the coarse and fine temperature controls to indicate a temperature of 130º f above ambient.

2.27 Allow the function simulator about 3 minutes to warm up and then switch the function simulator gate switch to ON.

2.28 On the test panel select RAIL 1.

2.29 Adjust RAIL 1 pulse processor unit GAIN control to give a test panel deflection meter reading of (see Table 1):

<table>
<tr><th>Equipment Type</th><th>Reading</th></tr>
<tr><td>7788</td><td rowspan="2">6mm</td></tr>
<tr><td>7789</td></tr>
<tr><td>7788R</td><td>12.5mm</td></tr>
<tr><td>8889</td><td rowspan="2">12mm</td></tr>
<tr><td>8889R</td></tr>
</table>

Table 1 – Deflection Readings

2.30 Check that the deflection meter reading is steady, any variations should not exceed + 0.5mm.

2.31 Move the function simulator to RAIL 2 and select RAIL 2 on the test panel.

2.32 Repeat items 2.26 to 2.27 and adjust RAIL 2 pulse processor unit GAIN control.

2.33 Remove the function simulator from the scanner.

2.34 Switch the function simulator gate switch off and switch the power switch off.

2.35 Disconnect the function simulator from the data processing unit.

SERVOTRIM SERIES

Includes:	Servotrim 9909
Excludes:	Servosafe 7788, 7788R, 7789, 7789R, 8889, 8889R

SERVICE A TESTS

3. DPU Keypad Tests

3.1 Press * to enable the keypad. Then check the date and time:

a) Press D/ENT/2/ENT/

b) Check that time and date are correct. Press * to clear.

If not correct:

c) Press D/ENT/ - followed by: Month/ENT/Day/ENT/Year/ENT/Hour/ENT/ Minute/ENT/ENT/

d) Check again and press * to clear.

Should the readings have been more than a few minutes out, report it as corrective maintenance.

3.2 Check the alarm level:

a) Press E/ENT/1/ENT

b) Check that alarm level E1 is set to 14.

If wrong, enter the correct value and press:

c) ENT

d) Press /ENT/ again and E2 will be displayed. Continue in this way and check/correct values:

e) E1=14; E2=14; E3=08; E4=08; E5=08; E6=08.

If any values are found to be incorrect, report it as corrective maintenance

3.3 Run the processor and integrity tests:

a) Press C/ENT/3/ENT

b) Check that A1 is displayed.

c) Press * to clear.

3.4 Place thermometer outside in the shade near to the temperature probe and allow to stabilise.

a) Press C/ENT/5/ENT

b) Check that the display corresponds to the thermometer ±2° F. Press * to clear.

3.5 Shut down the keypad:

a) Press F/ENT

3.6 Where practicable, count the number of axles on two trains and check with the Signaller that the signal box received the same.

SERVICE B TESTS

4. Signal Box Display Equipment

4.1 Unplug the transmission line from the back of the modem and check that a ‘Comms Alarm’ is received.

4.2 Replace plug and check that the alarm is cancelled correctly.

4.3 Where the readout is computer based, switch the power off, leave for 10 seconds and power up.

4.4 Check that the computer boots up correctly and, where possible, that the next train is correctly reported.

5. Keyboard

5.1 Check that the system responds to a keyboard command by typing:

S/RETURN

NOTE: *This performs a self-test, and the ensuing report should be examined on the printer (i.e., "system test: passed + date and time).*

6. System Functions

NOTE: *Each time the sensor is adjusted, it is necessary to refresh the display by entering: C/ENT/5/ENT*

6.1 Plug the function simulator cable into the back of the DPU and the function simulator.

6.2 Set the function simulator to 130º F above ambient temperature, turn on the gate switch and power switch, and allow to warm up.

6.3 When the neon indicator is seen to be cycling on/off, place the saddle on the trailing end of rail 1 scanner and place the function simulator onto the saddle.

6.4 On the DPU Keypad press:

a) C/ENT/2/ENT

b) Check that the lowest cycling point on the display is 12.0. If it's not, adjust R58A on the front edge of board 2 of DPU.

6.5 Using a digital voltmeter, measure the voltage between TP61A (+) and TP78A (-)

- 2VDC (±0.05V). If it is outside these limits, adjust R13A to correct.

6.6 Move saddle and function simulator across to rail 2 scanner.

6.7 Check that the lowest cycling point on the display is 12.0. If it's not, adjust using R48A on the front edge of board 2 of the DPU.

6.8 Using a digital voltmeter, Measure the voltage between TP52A (+) and TP78A (-)

- 2VDC (±0.05V). If it is outside these limits, adjust R17A to correct.

NOTE: *It should be borne in mind that the values in 6.4/6.5 and 6.7/6.8 are interrelated and should be rechecked if either pair are adjusted.*

6.9 Switch the function simulator “gate” off and remove the function simulator from the scanner.

6.10 If any adjustments have been made in 6.5; 6.6; 6.7 or 6.8, benchmark the equipment by pressing C/ENT/2/ENT/*

Holding the * in until the function simulator LED on the front panel goes out. Then (within 5 secs) Press C/ENT/1/ENT

This initiate an integrity test.

Record the integrity values displayed. Press * to clear the display and exit.

6.11 Recover the function simulator, saddle, and cable from the track.

CYBERSCAN 2000 (TRIM II)

7. DPU Tests

Use a laptop or desktop PC to carry out these tests via the DPU interface terminal.

Report as corrective maintenance if any of the tests fail.

7.1 Check and Record the DPU time by typing:

NOW/ENT

7.2 Check and Record the system parameters and software installed by typing:

VER/ENT

7.3 Check and Record the system integrity by typing:

I or INTEG/ENT

END

Caution: 7788 HABD Equip is fragile, primarily due to its age. Care shall be taken when working on this equipment.

NOTE: *Excessive power down & up cause component failure.*

Inform the Signaller that routine tests are being carried out.

Carry out test between trains.

These tests refer to the signal box end of the equipment. Before starting the full alignment test check the scanners are aligned to each other.

This confirms that, once all checks have been carried out, the scanners should be looking at the same area, each side of the same axle of the passing train. Until this is achieved the tests will not be effective.

Check the alignment jig to confirm it is not bent, as it is easily mis-shaped due to bad storage or misuse.

Scanner & bolometer lens covers need to be removed. The centre of bolometer lens can now be obtained, and a straight line drawn across rail top. This can be done by using a large T square or the servo alignment jig by looking vertically down at the lens until the edge of the horizontal 'bar' is square to the running rail and aligns with the centre of the bolometer lens. R1 & R2 bolometer rail top marks should align.

Adjust scanner metal base plate to align scanners. Check that the scanner base has not moved backward or forward after this alignment or has been moved up/down or in/out to the rail.

If unable to initially align scanners inform your SM(S).

1. Alignment of transducers and optical alignment of scanners ballast mounted scanners

1.1 Check that the system is either powered down as per notes in the general section of each equipment type or the system is disconnected from the Signal Box.

NOTE: *Appendix A shows the details for Servosafe (Figure 2) rail mounded scanners, Servotrim systems (Figure 3), and Trim II systems (Figure 4). The transducers are marked as A, B & C.*

1.2 Fit the alignment jig & target mirror (Appendix C).

a) Establish the centre of the scanner lid aperture, square to the running rail.

b) Mark across the rail top for this position, complete for both scanners.

c) Check both R1 & R2 rail top marks align.

d) Move scanners to achieve alignment. If unable to align scanners report it as corrective maintenance.

e) Check that the positions of the transducers.

f) Measure ‘Z’ distance from the centre of each bolometer lens, mark on rail top towards ‘A’ & ‘B’ transducers.

g) Mark each rail at this point.

h) Note the measurement (via alignment jig) at which the centre of the fixture post sits, compare this measurement with the fixture bar setting table (Appendix B).

1.3 Report as corrective maintenance if the fixture bar measurements is outside those given in the setting table.

1.4 By use of a ferrous object, establish and mark the magnetic centres of the transducers A and B.

- If Servotrim transducers are used the magnetic centre can be found by use of an Allen key held in the hand.
- If Servopole transducers are used mark the ‘physical’ centre manually.

1.5 The scanner to transducer rail top mark now becomes the datum mark for A & B transducers.

a) Measure from this datum, distance ‘X’, marking the rail top. Then distance ‘Y’ and again mark the rail top. Marks first made on the transducers, in 1.2 should align to the marks on the rail top - distance ‘X’ & ‘Y’.

b) Adjust transducers to confirm alignment.

c) If unable to align, inform SM (S).

1.6 Check the alignment for ‘C’ Transducer. If unable to align, inform SM (S).

1.7 Check that the scanner mounting metal base plate is level by using a spirit level.

a) View the mirror through the hole in the target plate.

b) Check that the red spot appears within the black circle. Section 3 lists actions to be taken if the red spot is outside the black circle.

c) Report as corrective maintenance if any of these actions fail to solve the problem.

1.8 Remove alignment jig & target mirror and refit the lens cover and scanner housing.

1.9 Repeat as per 1.2 to 1.5 for the second scanner (rail top marking only required for the transducer rail).

1.10 Check external anti-vibration mounts are not excessively loose. Visually check, where possible, for deterioration.

1.11 Refit the lens cover and scanner housing.

1.12 Restore the power to the equipment as per notes in the general section of each equipment type or reconnect the system to the Signal Box.

Remember to allow the system to stabilise after being powered down as per the notes in the general section of each equipment type before handing back to the Signaller.

2. Alignment of transducers and optical alignment of scanners rail mounted scanners

2.1 Check that the system is either powered down as per notes in the general section of each equipment type or the system is disconnected from the Signal Box.

NOTE: *Appendix A shows the details for Servosafe rail mounded scanners, Servotrim systems, and Trim II systems. The transducers are marked as A, B & C.*

2.2 Check that the cant nuts are all set to the same number. For 113lb flat bottom vertically inclined rail the lowest number on the cant nut is used (positioned at the top).

2.3 Fit the alignment jig & target mirror (Appendix C).

a) To obtain the scanner to transducer datum mark, position the assembled alignment jig on the scanner/transducer rail.

b) Move the alignment jig towards A & B transducers until the target mirror red dot is within the black circle of the target plate.

c) Check that the alignment jig sits correctly on the rail and the fixture post and target plate are secure when aligned with target.

d) Mark the rail top with the centre of the alignment jig position at this point.

e) Note the measurement (via alignment jig) at which the centre of the fixture post sits and compare this measurement with the fixture bar setting table (Appendix B – Figure 6).

2.4 Report as corrective maintenance if the fixture bar measurements is outside those given in the setting table.

2.5 By use of a ferrous object, establish and mark the magnetic centres of the transducers A and B.

- If Servotrim transducers are used the magnetic centre can be found by use of an Allen key held in the hand.
- If Servopole transducers are used mark the 'physical' centre manually.

2.6 The scanner to transducer rail top mark now becomes the datum mark for A & B transducers.

a) Measure from this datum, distance 'X', marking the rail top.

b) Then distance 'Y' and again mark the rail top. Marks first made on the transducers, in 2.3, should align to the marks on the rail top - distance 'X' & 'Y'.

c) Adjust transducers to confirm alignment.

d) If unable to align, inform SM (S).

2.7 Check the alignment for 'C' Transducer. If unable to align, inform SM (S).

2.8 Check that the scanner mounting metal base plate is level by using a spirit level.

a) View the mirror through the hole in the target plate.

b) Check that the red spot appears within the black circle. Section 4 lists actions to be taken if the red spot is outside the black circle.

c) Report as corrective maintenance if any of these actions fail to solve the problem.

2.9 Remove alignment jig & target mirror and refit the lens cover and scanner housing.

2.10 Repeat as per 2.2 to 2.9. for the second scanner (rail top marking only required for the transducer rail).

2.11 Check external anti-vibration mounts are not excessively loose. Visually check, where possible, for deterioration.

2.12 Restore the power to the equipment as per notes in the general section of each equipment type or reconnect the system to the Signal Box.

Remember to allow the system to stabilise after being powered down as per the notes in the general section of each equipment type before handing back to the Signaller.

3. Suggested action to be taken if alignment is incorrect for ballast mounted scanners

This is a list of suggested actions to be taken to correct alignment; they are not mandated actions to be taken in all cases.

3.1 Check the scanner unit mounting base/plates are not obstructed by ballast or other objects preventing adjustment.

3.2 Check that the scanners are still aligned to each other if any additional adjustment is carried out i.e. A combination of adjusting the scanner metal base plate up or down, in or out to the rail, along with the bolometer mounting base, should enable compliance with 1.2.

After adjustment, check that the metal base plate is level by using a spirit level.

3.3 Check the scanner unit mounting base/plates have adjustment available.

Inform your SM(S) if no adjustment available to comply with 1.9.

3.4 Check for damage to the scanner metal base plate i.e. bent, mis-shaped.

Usually after being driven over by RRVs or hit by Tamper's.

Inform your SM(S) if plate is damaged.

3.5 Check for damage to the metal base plate mountings.

Inform your SM(S) if mountings are damaged and or preventing compliance with 1.9.

3.6 Check bolometer anti-vibration mounts are not deteriorated or have been damaged. Replace if necessary.

3.7 Check alignment bar is in correct position i.e. middle of bar aligns with the Z distance (Appendix B) rail top mark.

a) Check fixture post set to correct setting.

b) Check the alignment bar is flush/pushed down onto the rail top.

Alignment checks should be combined with an onsite 'system check'. Other than 'fault conditions' or equipment replacement after track work, is usually undertaken every 12 months'.

4. Suggested action to be taken if alignment is incorrect for rail mounted scanners

4.1 Check the scanner is secure and correctly fitted. Loose fixing bolts or dirt/debris behind the clamps.

4.2 Check that the scanner and is not damaged (e.g. hit by an object hanging from a train). Correctly secure or replace as necessary.

4.3 Check that the correct alignment can be obtained within the tolerances given in Appendix B.

4.4 Check that the railhead does not have a layer of swarf/rust or has burrs. Clean or Rectify as required.

4.5 Check that the scanner mountings are not deteriorated, replace if necessary.

4.6 Check that the internal anti-vibration mounts are not deteriorated or have been damaged. Replace if necessary.

4.7 Check if provided, the scanner cant clamp nut (or cant cam).

On 113lb flat bottom vertically inclined rail this should be at the lowest number, positioned at the top.

If the fixture bar measurements cannot be obtained (with cant nuts correct) and no spare scanner is available, additional special packing pieces (fit between the anti-vibration pads and scanner body) are available to adjust scanner alignment, if required.

Advise your SM(s) if packings are required.

Note that this may have been adjusted previously to obtain correct alignment.

4.8 If none of the previous steps solve the problem, replace the scanner with a known 'good' unit and recheck the alignment.

APPENDIX A - Equipment Positions

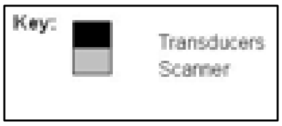

Figure 1 - Positioning of transducers and scanner (not to scale)

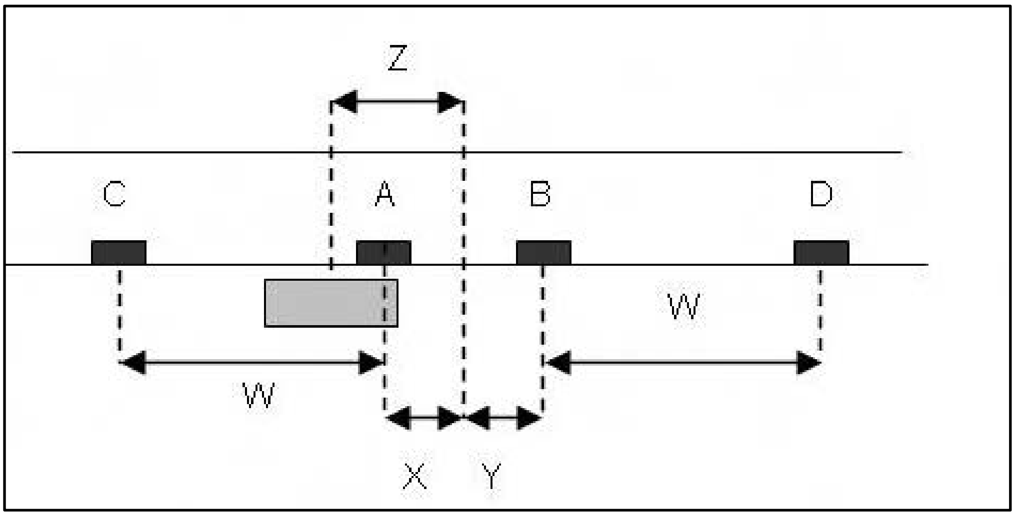

Figure 2 – Servo Safe Series

NOTE: *The Servosafe diagram shows rail mounted scanners*

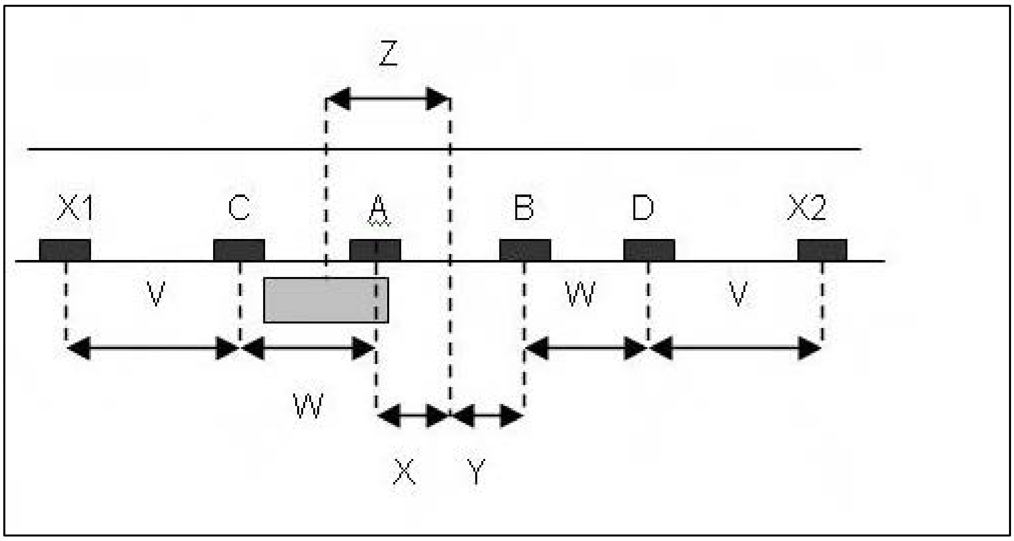

Figure 3 – Servotrim Series

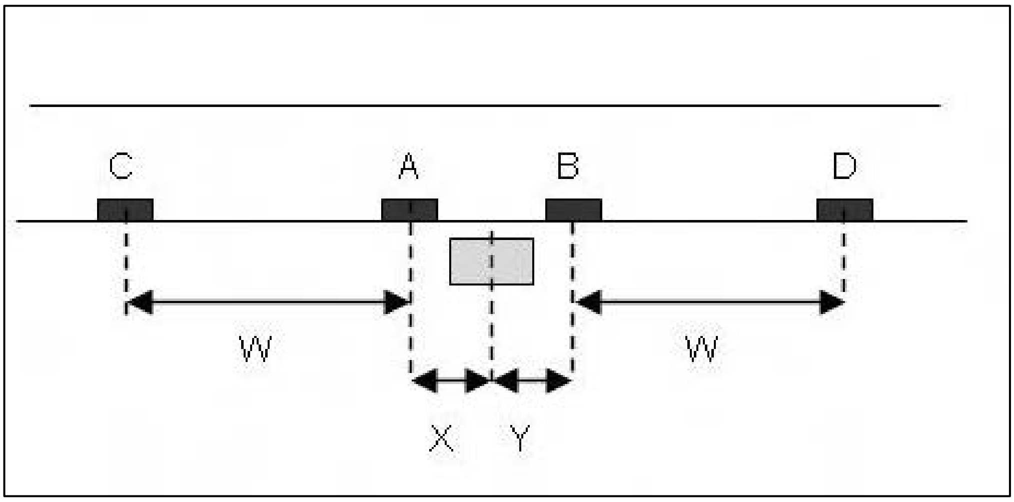

Figure 4 – Trim II Series

APPENDIX B - Setting Tables

Equip. Type	Distance (Inches)				
	W	X	Y	X+Y	Z
7788	433 ±6	10	10	20	35¾
7788R	433 ±6	12	12	24	19½
7789	433 ±6	10	10	20	35¾
8889	433 ±6	12	12	24	19⅓
8889R	433 ±6	12	12	24	20⅔
9909	864 ±6	13½	13½	27	20⅔
Trim II	480 ±6	13½	13½	27	0

Table 1 – Distance Setting Table

NOTE: *Distant Z can vary on older systems, it is important that the scanners are aligned to each other. See the general section.*

Distance Z is between the centre points of X/Y and the centre of the scanner mirror/aperture.

Distance 'V' (X1/2 to C/D transducers) is applicable only to the Servotrim 9909 series (transducers X1/2 are on this system only) and is a distance of 500 feet (±10 inches).

Distances V, W, X and Y are between the magnetic centres not the physical centres

Equipment Type	Fixture Bar Setting (inches)
7788 and 7789 rail mounted scanners	14.5
7788 ballast mounted scanners	13.5
7788R	6.75 (+¼ / - ½)
8889	13.125
8889R	6.75 (+¼ / - ½)
9909	6.75 (+¼ / - ½)

Table 2 – Fixture Bar Setting Table

APPENDIX C - Scanner Alignment

NOTE: *The diagrams shows rail mounted scanners:*

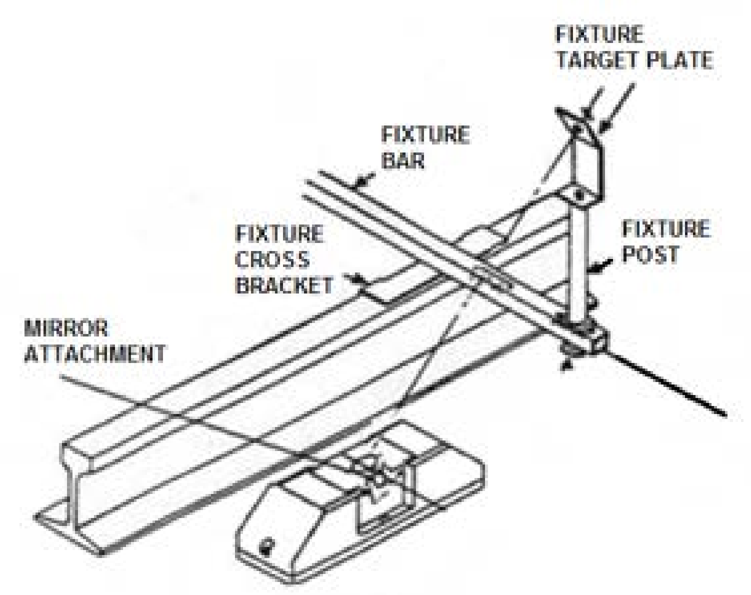

Figure 5 – Scanner Alignment

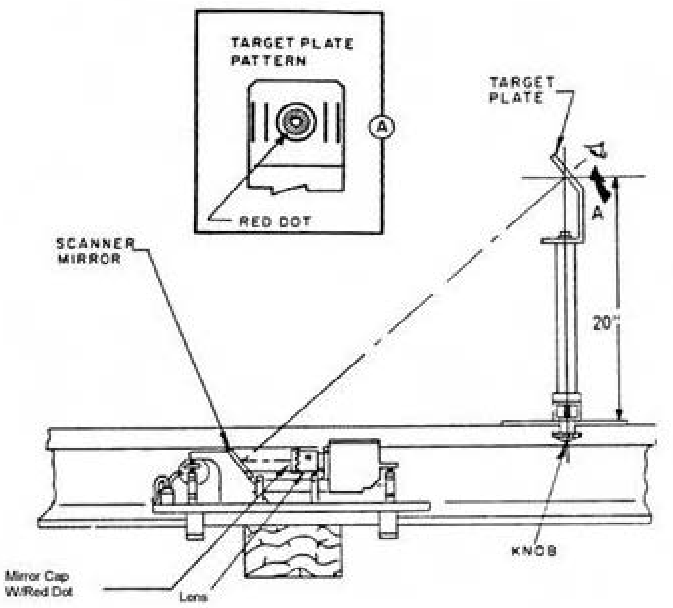

Figure 6 – Scanner Alignment 2

END

Advise the Signaller a functions test is to be performed on the system.

1. Test HOAL

1.1 Set the heat source to 110C + Nom Temp (i.e. 10 degrees higher than the alarm threshold).

Warning: Do not touch the black surface of the heat source.

1.2 Place the heat source above the shutter opening with the heated surface pointing to the shutter opening.

1.3 Use the train simulator unit to simulate the passage of a train with speed set to slow and number of axles set to 32.

1.4 Remove the heat source after 7 seconds and await the unit to finish processing the data.

1.5 Use the Terminal / Menu X / B-last trains / X Showax menu to check the charts of each sensor element is displaying the correct temperature.

1.6 Check the data for the last train (i.e. the simulated train) confirming each axle raised an alarm.

1.7 Check with the Signaller that an alarm has been raised for the correct temperature and number of axles.

1.8 Where necessary undertake any corrective action. This may include re-aligning the sensor elements using the alignment matrix (see NR/SMS/PartE/HO11 – HABD Equipment GETS FUES - Appendix B).

2. Test HOAR

2.1 Repeat steps 1.2 to 1.8.

3. Test FBOA

3.1 Set the heat source to 410C + Nom Temp (ie. 10 degrees higher than the alarm threshold).

3.2 Repeat steps 1.2 to 1.8.

END

Includes:	SSI Datalink
Excludes:	All other types of datalink

GENERAL

Records shall be kept for a minimum of five years.

Health Check Tests

Sections 1 and 2 require the use of a datalink analysis device capable of counting blips and incomplete, damaged, or incorrect telegrams on an SSI datalink. Any unit with this functionality can be used, provided that it has been accepted by Network Rail for attachment to SSI datalink test points for the purpose of datalink monitoring.

Accepted datalink analysis devices available at the time of writing are the PTERTS, the SLA. REMIT detect and REMOSdl.

Section 3 requires use of an SSI datalink interrogator and a digital storage oscilloscope. More details on these appear in the 'DLM Tests' text preceding Section 3.

This monitoring equipment shall only be fitted by an 'Instrumentation Engineer' (Oscilloscope) or a 'Special User' (PTERTS, SLA, REMIT and REMOS) who has been trained in its use.

Before fitment, the engineer shall specifically consider power supply arrangements, connections to the datalinks and any address changing necessary.

In electrified areas, the following tests shall be carried out while a representative electric service is being run (or at least two electric trains shall pass through the testing area during the period of testing).

The SLA does blip detection and telegram error detection simultaneously, thus Clauses 2.1 - 2.3 below are not required.

REMITdetect has been specifically designed to cover the maintenance requirements for data links and hence many of the steps herein are automated by the use of this tool.

The SLA also has an internal logging feature which should be enabled during the testing; the internal log should be provided to your SM(S) if either the blip count or telegram error rate is exceeded.

SERVICE B TESTS

1. Blip Detection

1.1 Follow the manufacturer's operating manual to set up the datalink analysis device. The correct power supply connection is required for both PTERTS and the SLA, dependant on the monitoring time.

1.2 For the PTERTS only, set the unit to count blips.

1.3 Observe that the unit is detecting blips (on the PTERTS an LED indication pulses when a blip is encountered, the SLA shows activity on the display screen and blip and other counts at the top) and leave the unit to obtain a representative count.

1.4 Observe that the unit is detecting blips (the LED indication pulses when blips are detected) and leave the unit to obtain a representative count.

On busy lines, an hour during daytime should be adequate; on lightly used lines, a full day is more appropriate.

1.5 Record the times and count obtained.

If the blip count is greater than 5/hr, further investigation shall be undertaken to determine the cause of the level of errors and corrective actions taken.

2. Telegram Error Detection

If using the SLA or other device that automates the telegram selection; proceed to step 2.3 using the data obtained from Section 1.

2.1 Connect a correct power supply to the datalink analysis device. Set the unit to the local datalink address.

2.2 Connect the datalink analysis device input leads to the system test points (usually at the interlocking but can be at any location on the system).

2.3 Observe that the unit is detecting valid telegrams (the LED indication illuminates when valid telegrams are detected) and leave the unit to obtain a representative count.

On busy lines an hour during daytime should be adequate; on lightly used lines a full day is more appropriate.

2.4 Record the times and count obtained.

A desirable error rate is 0 in a 24-hour period. If the rate is greater than 120 in a 24-hour period, further investigation shall be carried out to explain the rate and remedial action carried out as necessary.

NOTE: *That where separate counts are provided for coding, parity, and corruption errors; check that the test for desirable error rate is carried out using the total telegram error rate.*

3. DLM Baseband Datalink Tests

The following tests are to find damage within the DLMs.

The transmitted signals can appear as asymmetric or a higher output than normal.

In addition, damage to the lines can show as an abnormal attenuation.

Since a ‘back-to- back’ repeater site can correct any asymmetry and amplitude problems during re-transmission (as can an LDT in the line) it is necessary to test each baseband section of the datalink between repeaters or LDTs separately.

The datalink schematic can be used to decide on a suitable base site for each baseband section (the interlocking should be one site as it does not involve LDTs).

The chosen sites should be used for all subsequent testing as this maintains a useful reference for the readings.

The SSI datalink interrogator and a digital storage or other suitable automated test equipment should be used for the tests.

Where the datalink interrogator method is used this shall be configured to trigger the oscilloscope at the correct time and the equipment shall be connected as per Appendix A.

Refer to the manufacturer’s instructions for connection of other automated test equipment.

The planning shall specifically consider the power supply arrangements, earthing and where to connect the datalinks before starting work.

3.1 Select the base site on a metallic link, connect the test equipment in a relevant manner for the equipment being used.

Where applicable for the test equipment, set the interrogator for interlocking (outgoing) telegrams and monitor the address for the base site.

3.2 Measure the amplitude of the telegram transmission or select the relevant test from an automated test tool such as REMOSdl.

While the system can operate with a waveform between 0.5v and 6 v peak to peak readings below 1v and above 5v peak to peak shall be highlighted for further investigation.

3.3 Measure the symmetry of the telegram transmissions. Check they are not distorted.

NOTE: *Up to 50mV peak asymmetry is acceptable.*

Where asymmetric telegrams are found, the DLM associated with this telegram shall be changed.

3.4 Measure the telegram transmissions for pronounced overshoot in the offset waveform after the last edge of the transmission.

- Up to 150mV peak is acceptable.

3.5 Check that there is no line noise between telegrams

- Up to 100mV peak to peak is acceptable.

3.6 Check that the telegram amplitude does not vary within each message.

- Up to 10% of the peak amplitude is acceptable.

3.7 Repeat 3.1 to 3.4 for every DLM on the baseband link (this can be done automatically when using a tool such as REMOSdl, (Appendix B).

As well as review of the reply telegram amplitude against the expected norm for a data link of the relevant length, the readings shall be reviewed against previous actual measurements for the data link concerned. Any discrepancy with either review shall be recorded and investigated further.

3.8 For each section of baseband data link bounded by a DLIT or Back to Back repeater, carry out the Non-Intrusive Earth Leakage Test detailed in section 11.5.4 of NR/GN/SIG/19054-11.

For any cable section where this test method indicates a reading below 10Mohm, further investigation is required to find the cause.

There are many reasons for poor earth readings which include cable damage and surge protection failure. Carry out necessary checks on relevant items and repair or replace as required to achieve a reading of >10Mohm.

3.9 Where readings remain above 10Mohm, the latest measurements shall be compared with previous test results to determine the rate of degradation.

If any increase or sudden change is identified, further investigation shall be planned to address the situation, before the readings fall to levels which might affect stability.

4. LDT Tests

Testing on a system with LDTs is carried out in a manner very similar to baseband links.

4.1 The base site shall be after the LDT link on the metallic section of the system which normally rules out the signal box as the base site.

4.2 It shall be remembered that on systems using LDTs replies are returned to the interlocking in the reply period of the minor cycle subsequent to that in which the initiating outgoing telegram was sent.

4.3 LDTs are treated as for back-to-back repeaters and a single address of a TFM beyond an LDT shall be included in the list compiled from the datalink schematic.

4.4 The same procedure detailed in Section 3 ‘DLM Baseband Datalink Tests’ shall be used for testing a system with LDTs, taking into account the comments in this section.

APPENDIX A - SSI BASEBAND DATALINK TESTING INSTRUMENTATION SET UP

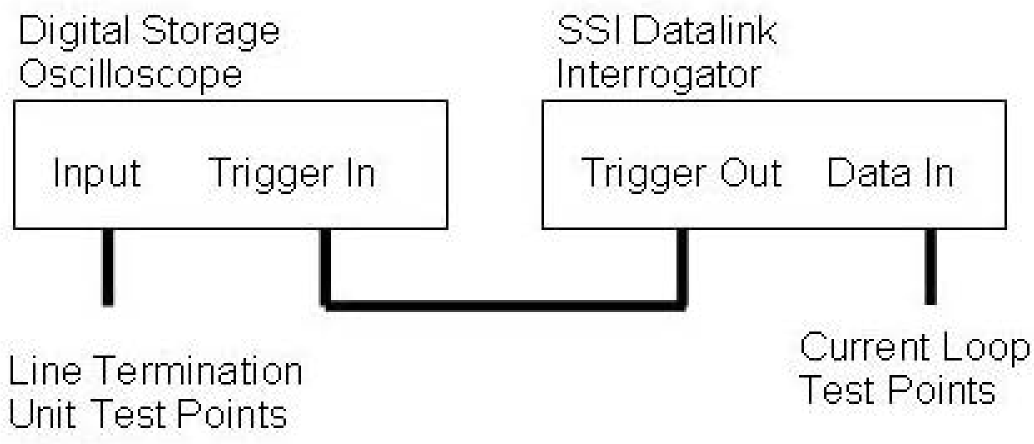

Figure 1 – SSI Baseband Datalink Testing Instrumentation Set Up

APPENDIX B - DLM Baseband Datalink Testing

When an automated test tool is not available, it is required to repeat the test in Section 3 to monitor and record in turn every DLM on the baseband link and hence the requirements of this appendix apply.

1. The datalink schematic should be consulted to produce a list of DLM and TFM addresses. The rules of compiling this list are as follows:

   a) Review the datalink schematic to identify each dlm and then choose one tfm address serviced by it (some dlms service more than one tfm, it is only necessary to see replies from one of those tfms).

   b) If the base site is not the signal box or the origin of the datalink it is necessary to see a reply from a tfm at the base site. This should be added to the list.

   c) Where back-to-back repeaters are provided, it is necessary (to prove the operation of the repeater dlm itself) to select a single address somewhere in the section beyond the repeater. This should be added to the list.

   d) Work through the list setting the datalink interrogator for trackside (incoming) telegrams and its address to each of the tfms on the list taking measurements in turn.

   e) Review the results for the datalink, there should be a gradual decline in the signal levels in line with the distance away from the transmitting tfm. Any measurements outside the specified limits require remedial action.

END

Includes:	GEC Over-Ride System
Excludes:	All other Ove-Ride Systems

General

This test makes sure that the remote control 'over-ride' system works when it is required to.

Because it affects the available signalling routes, you shall make arrangements with the signaller before attempting this test.

The signaller is responsible for the safety of trains and shall give you permission to start.

1. Over-Ride Test

1.1 Check that the remote control normal white indication is showing on the control panel.

1.2 When the signaller gives you permission to do so, turn the emergency route setting switch from 'Normal Working' to 'Auto-Working'.

1.3 Check that:

a) The system sets the defined routes.

b) The routes are correctly indicated, and

c) The signals are shown to clear on the signal box panel.

1.4 Turn the emergency route setting switch from 'Auto- Working' to 'Signals On'.

1.5 Check that:

a) All controlled signals return to danger.

b) The signals are correctly indicated on the signal box panel.

1.6 If facilities are provided for selective defined routes, repeat 1.2 to 1.5 for each set of routes.

1.7 Turn the emergency route setting switch to 'Normal Working'.

1.8 With the signaller's permission, set the defined routes on the panel buttons.

1.9 Turn the emergency route setting switch to 'Auto- Working' and Check that the aspects do not drop back by watching the indications on the signal box panel.

1.10 If facilities are provided for selective defined routes, repeat 1.7 – 1.8 for each set of routes.

1.11 Turn the emergency route setting switch to ‘Normal Working’ and Check the remote control normal indication is showing.

1.12 Check that routes can be set and cancelled via the normal method of remote control.

End

Includes:	BR Electronic Route Selection Equipment (ERSE) Mk2A and 2B
Excludes:	BR Electronic Route Selection Equipment (ERSE) Mk1

General

Due to operating conditions, not all of these tests may be possible to achieve.

Testing shall be carried out of those allowed by the Signaller with the others noted for testing at a low traffic period or when under a system possession.

1. Signal Box

1.1 Observe that the ERSE alarm indication on the Signaller's panel is extinguished.

Ask the Signaller if they are aware of any faults on the system.

1.2 Press and release an entrance button and observe that the button indication flashes.

Pull and release the button and observe that the button indication extinguishes.

Repeat for all entrance buttons.

1.3 Press and release an entrance button then press and hold a valid exit button for the entrance selected.

Check that after 5 to 30 seconds an audible alarm sounds with a visual indication. Operate the 'Alarm Acknowledge' button or switch and check that the alarm is silenced.

Release the exit button and cancel the route.

1.4 Repeat 1.3 but do not operate the 'Alarm Acknowledge' button or switch.

Release the exit button and check that the alarm cancels 1 second after the button is released.

Cancel the route.

1.5 Operate the Signaller's ERSE by-pass control and check that routes can still be set.

When in ERSE by-pass mode the points in the route must be operated manually via the point keys to the required position before pressing the entrance button only.

Extreme caution shall be observed that all the points in the route are set correctly, the route entrance signal shall clear when the entrance button is pressed irrespective of the lie of the points when in ERSE by-pass.

2. Equipment Room

2.1 Observe the LED and lamp indications on cards and power supply units in the equipment cubicle, check they indicate as follows:

Item	Colour	State
Monitor Units 2/2 or 2/3	Green	Illuminated
	Red TL	Illuminate only during route setting
	Red RP	
Route Cards	Red L1	Illuminate only during route setting
	Red L2	
	Red L3	
	Green L4	Illuminated
	Red L5#	Illuminated only when route is available
Input Cards	Green	Illuminated
PSUs	Red 110V	Illuminated
	Green 15V	

Table 1 - Indications

#: L5 LED is not provided on early versions of route cards.

2.2 Measure using a meter or oscilloscope the following DC output voltages and AC ripple from each power supply:

Supply	Limits	Ripple
15V	14.4V to 15.6V	<15mV
24V	24V to 30V	<3V

Table 2 - Output Voltages

3. Monitor Unit

3.1 On each monitor unit (2/2 or 2/3) press the test reset button.

This will apply a reset to all the route cards.

3.2 Connect a meter between the 0V and TL/RP test points in turn. Check that the following voltages are obtained:

Operation	Test Point	Voltage
Push Button Ring Free	TL	12V to 15V
	RP	
Push Button Ring In Use	TL	0V
	RP	

Table 3 - Test Point Voltages

4. Power Supplies

4.1 Switch all 15V PSUs off line. Observe that all the indication LEDs on the monitor, route and input cards are extinguished.

4.2 Switch off the 110V supplies. Remove the 15V PSUs from their housing. Visually check the electrolytic capacitors for any signs of leakage, swelling or general deterioration. If any is found, renew the PSU.

Electrolyte from capacitors is hazardous to heath, PPE (e.g. gloves) shall be worn when handing leaking capacitors.

4.3 Visually check the buffer relay 24V PSU electrolytic capacitors as in 4.2.

4.4 Replace the PSU's into their housing and restore the 110V AC supply.

Switch the PSUs on line and check that all alarms and indications normalise.

Measure the PSU outputs as listed in 2.2.

4.5 Check with the Signaller that route setting is working to their satisfaction.

END

1. Physical Checks

1.1 Check that markers are in place at 90%, 75%, and 50% of the approach length.

2. Detection Linearity Check and Lumped Impedance Adjustment

When carrying out this test, RX should only be expected to change when the termination shunts in use at the crossing are either narrow band shunts (NBS) or frequency selectable shunts (FSS).

No change in RX shunt shall be seen in cases where wide band shunts (WBS) are in use.

If such a change is noted, inform your SM(S) as it may indicate that the WBS in question is faulty.

Where narrow band compensation is in use, disable this for the duration of this test and re-enabled it once the test is complete.

Detection Linearity Check

2.1 With a clear track, set the RX to 100.

2.2 Connect a hard wire shunt at the HXP-3's approach termination and note the RX value; this should reduce to between 85 and 100.

2.3 If RX does not change, or increases with the shunt connection at the termination, move the hard wire shunt to 10% of the approach length inside the termination. RX should now be between 88 and 92.

2.4 Calculate what the expected RX should be at the 50% point. This is half of the RX value in step 2.3.

2.5 Move the hard wire shunt to 50% of the approach length and note the RX value again. If this figure for RX is more than 2 units away from the calculated figure, adjustment is required as described overleaf.

Lumped Impedance Adjustment

2.6 With the shunt at the 50% of the approach, advance to the LIA section of the IDK display by pressing the ADJUST SEL key until the present value for LIA begins to flash. On the "ADJUST" screen.

2.7 Press the ENTER button once so that the LIA prompt begins to flash and the value stops flashing.

2.8 While viewing the RX on the display, press the 2 (up arrow) button to count up, or the 3 (down arrow) button to count down until RX reads within 2 units of the calculated RX derived in step 1.5.

2.9 Press and hold the ENTER button until the LIA stops flashing.

2.10 Remove the test shunt at the 50% point.

2.11 For bi-directional HXP-3s, repeat this process for the opposite approach. When carrying out step 1.8, only make an adjustment when the RX is above the value calculated in step 2.5. Do not raise RX if the value is lower than that calculated for the second approach.

2.12 Repeat steps 2.1 to 2.11 for track 2 where present.

3. Island Check

3.1 Place a hard wire shunt on track 1 somewhere within the island.

3.2 Check that the island relay drive is de-energised and the (red) LOW LED located on the RSI module is on.

3.3 Move the shunt 5m outside the island and check that the (green) HIGH LED is on.

3.4 Check the island relay drive is energised. Remove the shunt.

3.5 If the island does not check out correctly, perform the island adjustment procedure.

END

1. Voltage Test

To check that accurate results are obtained, the following tasks shall always be carried out in the order that they appear in this document.

1.1. Measure and record the battery voltage on the +5V DC Power Supply Module at the + and – terminals of TB1.

If the result obtained is not between 4.5V – 5.5V DC, adjust the 12 volt feed by varying potentiometer R16.

In the event that is unsuccessful, inform your SM(S) such that arrangements can be made for the 5V DC Power Supply Module to be replaced.

1.2. Measure and record the output of the +5V DC Power Supply Module across TPI and TP2 of the Module.

1.3. Measure and record the voltage across TP1 and TP2 on the VLP module, which should be between 4.95V and 5.05V DC.

If the result obtained in task 1.3 is within the specified parameters, subtract the value obtained in task 1.2 from the value obtained in task 1.3 and record this on the record card before moving to clause 1.5.

If the result obtained in task 1.3 is not within the specified parameters, adjust the +5V DC Power Supply Module output voltage.

In the event that this is unsuccessful inform your SM(S) such that arrangements can be made for the +5V DC Power Supply Module to be replaced.

1.4. Operate the Power Supply Switch S1, located on the +5Vdc Power Supply Module, to the “OFF” position.

Measure and record and record the Lithium Battery voltage across TP1 and TP2 on the ACP Module and verify that this is between 3.25V and 3.75 V DC.

Operate the Power Switch S1, located on the +5V DC Power Supply Module, to the “ON” position.

If the result obtained is not within the specified parameters, inform your SM(S) such that arrangements can be made for the ACP module to be replaced.

For Interlocking only

1.5. On the NVIO module measure and record the following voltages:

a) Between TP1 and Com (10 to 38V)

b) Between TP2 and Com (10 to 38V)

END

Caution: where the records show that linearisation adjustment has been previously required, linearisation shall always be performed following calibration.

Calibration and Linearisation

Before proceeding with calibration, check the following:

a) All track bonding is good, and all termination shunts, insulated joint couplers, and track isolation devices (battery chokes etc) are installed in accordance with the design.

b) Due note is taken of the ballast conditions. If the level crossing predictor is calibrated under poor ballast conditions, it may require recalibration when the ballast conditions improve.

c) Enhanced detection is switched off.

d) There are no trains on the approach.

Calibration is required when:

a) Application programming is changed *

b) Modules are changed *

c) There are changes to the track infrastructure

* These tasks should be performed by technical support personnel following application programming change.

Calibration and linearisation should be performed as required by Table 1 in Appendix A.

All keys to be pressed during calibration and linearisation are on the level crossing predictor keypad (LCPK). All references to displays refer to the level crossing predictor display (LCPD).

1. Physical Checks

1.1 Check that markers are in place at 70% and 50% of the approach measured from the crossing.

2. Calibration

2.1 Check in the design details if enhanced detection (ED) is switched on. If ED is not switched on, proceed to Step 2.7

2.2 Press the TRACK 1 key.

2.3 Press the FUNCTION key.

2.4 Press the DOWN ARROW key until 'ENHANCED DETECTION' appears for the appropriate track.

2.5 Press the NEW DATA key.

2.6 Observe that 'ENHANCED DETECTION: OFF' is displayed for the appropriate track.

2.7 Press and hold the SETUP key.

2.8 Observe that 'SETUP T1 for Calibration is displayed.

2.9 Release the SETUP key.

2.10 Press the ENTER key.

2.11 Observe that 'SETUP T1 IN PROGRESS' is displayed.

2.12 After approximately 60 seconds Observe that 'SETUP T1 COMPLETE' is displayed.

2.13 Observe that calibrated values of EZ and EX are displayed.

2.14 Record the values of EZ and EX on the record card.

2.15 If the value of EX is 40 or lower, or the value of EZ is 115 or higher, inform your SM(S) immediately.

2.16 Measure and record the voltage between the Z1 and COM terminals on the appropriate 80012 track transceiver module.

2.17 Measure and record the voltage between the Z2 and COM terminals on the appropriate 80012 track transceiver module.

2.18 If the value of Z1 – COM or Z2 – COM is outside the range 7.5V to 10.0V DC, or the difference between the two values is greater than 0.5V DC, inform your SM(S) immediately.

2.19 Where Track 2 is present, repeat Steps 2.1 to 2.18 for Track 2.

2.20 If Linearisation is not required for either track, proceed to section 4.

3. Linearisation

Perform this section for each track that requires Linearisation.

3.1 Press the TRACK 1 key.

3.2 Press the SETUP key for approximately 3 seconds and then release.

3.3 Repeatedly press the DOWN ARROW key until 'SETUP T1 FOR LINEARISATION' is displayed.

3.4 Press the ENTER key.

3.5 Observe that 'LINEARISATION T1 VALUE:?? EZ:??' is displayed.

3.6 Press the NEW DATA key.

3.7 Press the UP ARROW key or the DOWN ARROW key until 'LINEARISATION T1 VALUE:+0 EZ:??' is displayed.

3.8 Press the ENTER key.

3.9 Place a short circuit across the termination shunt on the normal approach.

3.10 Observe and record the EZ value.

3.11 Calculate and record what the expected EZ should be at the 50% point. This is half of the EZ value in step 3.10.

3.12 Move the short circuit to the marker at 50% of the approach length and record.

3.13 If the level crossing predictor is configured as a unidirectional (or simulated bidirectional) crossing (see the design details) proceed to step 3.18.

3.14 Place a short circuit across the termination shunt on the other approach.

3.15 Observe and record the EZ value.

3.16 Calculate and record what the expected EZ should be at the 50% point. This is half of the EZ value in step 3.15.

3.17 Move the short circuit to 50% of the approach length and record the EZ value.

3.18 Press the SETUP key for approximately 3 seconds and then release.

3.19 Repeatedly press the DOWN ARROW key until 'SETUP T1 FOR APPROACH LENGTH`' is displayed.

3.20 Press the ENTER key.

3.21 Observe that 'TERMINATE T1 APPROACH EZ:??' is displayed.

3.22 Press the NEW DATA key.

3.23 If there is no simulated track inductor on the crossing, enter the smallest EZ number recorded in Steps 3.10 and 3.15. Otherwise enter the EZ value from the approach without the simulated track inductor.

3.24 Press the ENTER key.

3.25 Observe that the display alternates between 'PROGRAM T1 APPROACH: ????' and 'PROGRAM T1 COMPUTED: ????'.

3.26 Record the values computed.

3.27 Note the highest 'NO LINEARISATION' EZ value recorded at the 50% points in Steps 3.12 and 3.17.

3.28 Note the Calculated EZ/2 value for the appropriate approach recorded in Step 2.31 or 2.36.

3.29 Compare the value noted in Step 3.7 with the value noted in Step 3.28. If the two values are within +/- 1 of each other, proceed to section 4.

3.30 Subtract the value noted in Step 3.27 from the value obtained in Step 3.28. Multiply this value by 2. If the value is greater than +/-25 inform your SM(S) immediately.

3.31 Press the SETUP key for approximately 3 seconds and then release.

3.32 Repeatedly press the DOWN ARROW key until 'SETUP T1 FOR LINEARISATION' is displayed.

3.33 Press the ENTER key.

3.34 Observe that 'LINEARISATION T1 VALUE:?? EZ:??' is displayed.

3.35 Press the NEW DATA key.

3.36 Press the UP ARROW key or the DOWN ARROW key until the displayed 'LINEARISATION T1 VALUE:?? EZ:??' value matches the amount noted in Step 3.30 (taking note of the sign of the number).

3.37 Press the ENTER key.

4. Completion

4.1 Check in the design details if enhanced detection (ED) should be switched on. If ED is not required, proceed to Step 4.7.

4.2 Press the TRACK 1 key.

4.3 Press the FUNCTION key.

4.4 Press the DOWN ARROW key until 'ENHANCED DETECTION' appears for the appropriate track.

4.5 Press the NEW DATA key.

4.6 Observe that 'ENHANCED DETECTION: ON' is displayed for the appropriate track.

4.7 Repeat as necessary for the second track.

5. Island Calibration

5.1 Check that the frequency select jumper on the 80211 island module is set in accordance with the wiring details.

5.2 Place a short circuit between the rails at the distance beyond the receiver rail connections specified for the corresponding island frequency in Table 2 in Appendix B.

5.3 Press and hold the island module 'Calibration Select' push button for 2 seconds until 'REL' appears on the module display.

5.4 Release the push button and then press and release it again within 2 seconds.

5.5 Observe that the module display shows 'CAL*'.

5.6 After approximately 6 seconds, observe that the display momentarily shows 'DONE'.

5.7 Observe that the display shows 'BOOT' for approximately 9 seconds.

5.8 Observe that the display alternates between the software version and the pickup delay setting.

5.9 If ‘FAIL’ appears in the display, turn the Island module power off and then on again, and repeat Steps 5.3 to 5.9 again. If ‘FAIL’ appears again, the Island module is faulty.

5.10 Once calibration is complete, check that:

a) The displayed frequency matches the design details.

b) The pickup delay setting matches the design details.

c) The island STATUS indicator on the front panel of the level crossing predictor is extinguished.

d) The island relay drive voltage is 0v DC measured across the island relay terminals on the front of the level crossing predictor.

5.11 Remove the short circuit installed in Step 5.2 and then Check that:

a) The Island STATUS indicator on the front panel of the level crossing predictor is illuminated.

b) The island relay drive voltage is greater than 10V DC measured across the island relay terminals on the front of the level crossing predictor.

5.12 Place a 0.5ohm shunt across the rails between the Island Transmit wires.

5.13 Check that the island relay drive is de-energised, the island STATUS indicator on the front panel of the level crossing predictor is extinguished, and the crossing warning sequence is activated.

5.14 Remove the shunt and wait until the crossing warning sequence is reset.

5.15 Place a 0.5ohm shunt across the rails between the island receive wires.

5.16 Check that the island relay drive is de-energised, the island STATUS indicator on the front panel of the level crossing predictor is extinguished, and the crossing warning sequence is activated.

5.17 Remove the shunt.

5.18 Repeat Steps 5.1 to 5.17 for Track 2 where present.

APPENDIX A - Requirement for Calibration and Linearisation

Program Change	Calibration	Linearisation
Increased number of tracks from 1 to 2	Track 2 Only	Track 2 Only
LCP Frequency	Both Tracks	Both Tracks
Unidirectional to Bidirectional Or Bidirectional to Unidirectional	Changed Track Only	Changed Track Only
Transmit Level Changed from: Medium to Maximum Or Maximum to Medium	Changed Track Only	Not Required
Approach Length	Changed Track Only	Changed Track Only
Ballast Compensation Value	Changed Track Only	Not Required

Table 1 - Requirement for Calibration and Linearisation

NOTE: *In the test all actions are written as applicable to Track 1. Where Steps are to be repeated for Track 2, any displayed messages referring to either 'TRACK 1' or 'T1' can be taken to refer to 'TRACK 2' or 'T2' as appropriate.*

Values shown as '??' depend on the installation.

APPENDIX B - Island Frequency and Shunt Distance

Island Frequency (kHz)	Shunt Distance (Feet/Meters)
2.14	84 (25.6m)
2.63	72 (22m)
3.24	55 (16.8m)
4.0	45 (13.7m)
4.9	39 (11.9m)
5.9	32 (9.8m)
7.1	29 (8.8m)
8.3	25 (7.6m)
10.0	22 (6.7m)
11.5	20 (6.1m)
13.2	17 (5.2m)
15.2	15 (4.6m)
17.5	14 (4.3m)
20.2	14 (4.3m)

Table 2 - Island Frequency and Shunt Distance

END

This test checks that both processor modules (PM) are capable of output and input to/from lineside equipment. Hot standby PMs are installed in modular equipment housings (MEH) or object controllers (OC). Refer to installation documentation to ascertain the provision of these facilities.

The test might affect all outputs and inputs to the PMs, therefore protection should be applied to the working railway in liaison with the Signaller and in accordance with technical instructions.

It is also essential that the Technician's facility monitoring the PMs should be manned for the duration of the test.

1. Installations with hot-standby PMs

Where installations have hot-standby PMs, check the changeover facility as follows:

1.1 Obtain a list of faults from the TF(L) or TF(R).

1.2 Check the standby OK LED is illuminated green.

1.3 Press the red changeover button on the front of the active PM to force a changeover.

1.4 Check the standby OK LED on both PMs show red briefly. The Active LED on the deactivated PM is extinguished and the Active LED on the activated PM is lit.

1.5 Check the activated PM is error free and has not created new faults by relisting and comparing the new fault list with the list generated in 1.1.

1.6 Repeat steps 1.2 to 1.5 to check that the changeover works in both directions.

1.7 If the changeover fails in either direction inform your SM(S)

2. Test as part of periodic maintenance

2.1 If this test was carried out as part of periodic maintenance, then repeat steps 1.2. to 1.5 to leave the PM pair on what was the off-line PM.

END

Includes:	Systems fitted with “only” IMC Boards
Excludes:	Systems fitted with “both” IMC & ACB Boards (see SMS/PartB/Test/082)

General

Before work is undertaken that affects the normal operation of the level crossing system, the Signaller shall be informed. Normally a possession of the equipment or a no train period is required.

1. Frauscher RSR123 Wheel Sensor Test (System Adjustment)

1.1 Before starting work, the system shall be powered down by the removal of the main supply fuse in the equipment case.

1.2 Disconnect the wheel sensor cable in the trackside connection box (GAK unit).

1.3 Connect a multimeter set on 0-1V DC to the AMB001 test box socket (See Figure 1). Press the toggle switch on AMB001 to the battery symbol. The multimeter reading shall be > 0.75 V, if not the battery of the test box AMB001 needs replacing.

Figure 1 – AMB001

1.4 Sensor System 1. Connect wire 1 (brown) to the red connector and wire 2 (yellow) to the black connector (See Figure 2). The adjustment procedure starts automatically. After approximately 10 seconds the multimeter shall show a value between 0.49 V and 0.515 V.

Figure 2 – AMB001 Connected

1.5 If the measurements are outside of this range then try re-aligning the head to the centre of the tolerances, reference NR/SMS/PartC/AX40 (Frauscher Advanced Axle Counter) - Periodic Task 3. If this is unsuccessful then the wheel sensor shall be replaced.

1.6 Within 50 seconds of test step 1.4, place the testing plate PB200 over sensor system 1 (see Figure 3) and check that the multimeter value is between 330mV and 375mV.

Figure 3 - PB200 Over Sys1

1.7 If the measurements are outside of this range then try re-aligning the head to the centre of the tolerances, reference NR/SMS/PartC/AX40 (Frauscher Advanced Axle Counter) - Periodic Task 3. If this is unsuccessful then the wheel sensor shall be replaced.

1.8 Reconnect the wires to the trackside connection box to wiring diagrams.

1.9 Sensor System 2. Connect wire 3 (green) to the red connector and wire 4 (white) to the black connector. The adjustment procedure starts automatically. After approximately 10 seconds the multimeter shall show a value between 0.49 V and 0.515 V.

1.10 If the measurements are outside of this range then try re-aligning the head to the centre of the tolerances, reference NR/SMS/PartC/AX40 (Frauscher Advanced Axle Counter) Periodic Task 3. If this is unsuccessful then the wheel sensor shall be replaced.

1.11 Within 50 seconds of test step 1.9, place the testing plate PB200 over sensor system 2 (see Figure 4) and check that the multimeter value is between 330mV and 375mV.

Figure 4 – PB200 Over Sys2

1.12 If the measurements are outside of this range then try re-aligning the head to the centre of the tolerances, reference NR/SMS/PartC/AX40 (Frauscher Advanced Axle Counter) - Periodic Task 3. If this is unsuccessful then the wheel sensor shall be replaced.

2. System Power Up

2.1 At the equipment case replace the main supply fuse to energise the system.

2.2 Check that the following LED indications are illuminated:

- 24vDC power supply - Green “DC Okay”.
- Buffer Module - Green “Status”.
- Telemetry module - Green “Power”.
- IMC Board – Green “Power” (for both channels, on all boards).

2.3 Observe both on-demand LEDs are illuminated momentarily and then go out.

2.4 The red indication LEDs illuminate, and the auditable warning device sounds for 60 seconds before the LEDs go out, the audible warning is silenced, and the crossing reverts to dark mode.

3. Wheel Sensor Test (Detection Capability)

3.1 Identify the Evaluation Board (IMC) related to the wheel sensor to be tested and check the section is indicating clear. The IMC Board should only have the two green power LEDs lit (Figure 5).

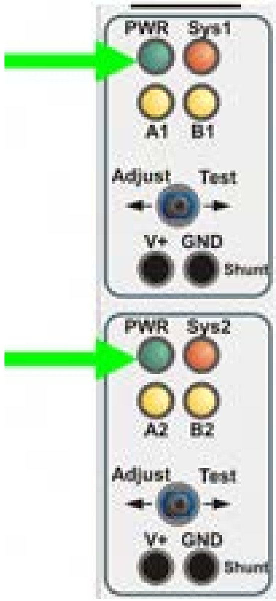

Figure 5 – IMC Board

3.2 Place the PB200 testing plate on the railhead to the left of the axle counter wheel sensor in the start position (Figure 6).

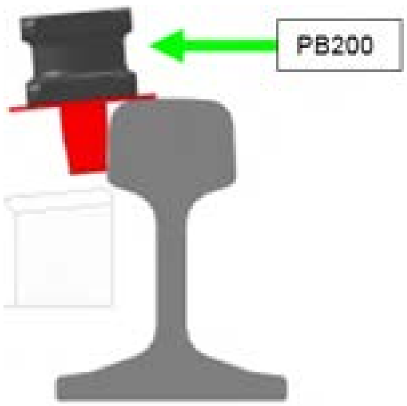

Figure 6 - PB200

3.3 Move (slide) the PB200 slowly in direction of arrow and stop over the first wheel sensor (Figure 7).

In the case of a VAMOS strike-in wheel sensor, Sys1 - Sys2 shall be in the direction of the strike-in.

Figure 7 – PB200 Over Sys1

3.4 Check the LED indications SYS1 and B1 are illuminated (Figure 8).

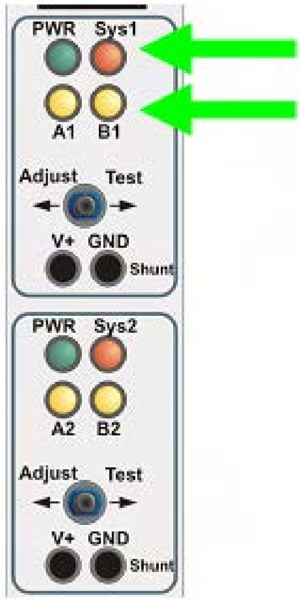

Figure 8 – IMC Board

3.5 Move (slide) the PB200 slowly in direction of arrow and stop at the mid-point between the two wheel sensors systems (Figure 9).

Figure 9 – PB200 over Mid Point

3.6 Check the LED indications SYS1, SYS2 and B1, B2 are illuminated (Figure 10).

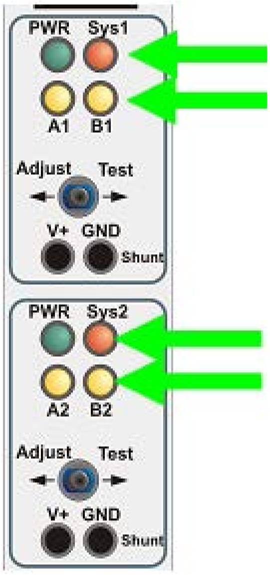

Figure 10 – IMC Board

3.7 Move (slide) the PB200 slowly in direction of arrow and stop over the second wheel sensor (Figure 11).

Figure 11 – PB200 Over Sys2

3.8 Check the LED indications SYS1 and B1 have extinguished and the LED indications SYS2 and B2 remain illuminated (Figure 12).

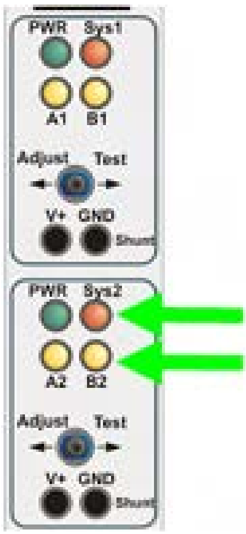

Figure 12 – IMC Board

3.9 At the end of the simulation, when the PB200 testing plate has passed beyond the sensor Check the LED indications SYS2 and B2 have extinguished on the IMC Board leaving the two PWR indications illuminated (Figure 13).

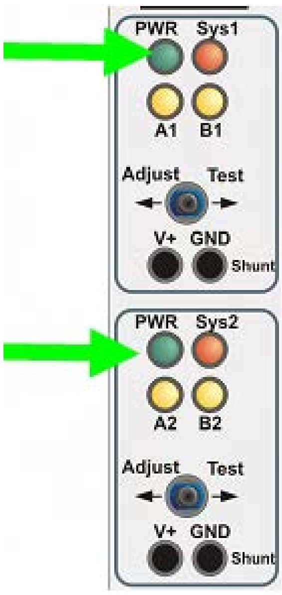

Figure 13 – IMC Board

3.10 There is no requirement to traverse over the wheel sensors in the reverse direction as the occupation times out.

END

Includes:	Vamos Level Crossing System
Excludes:	All other Overlay MSL crossings

GENERAL

The telemetry module has internal storage and writes the data's periodically onto the microSD card. Therefore, it is important to follow this procedure so is not lost.

1. Telemetry Data Logger

1.1 The Vamos System is fitted with a Telemetry Data Logger which both displays and records a number of parameters, making it straight forward to analyse and fault find on the system. (See Figure 1.

The system is fitted with a small screen and navigation buttons, allowing the user to scroll through its 5 screens. Each of the screen is broken into 6 lines each relating to a particular function.

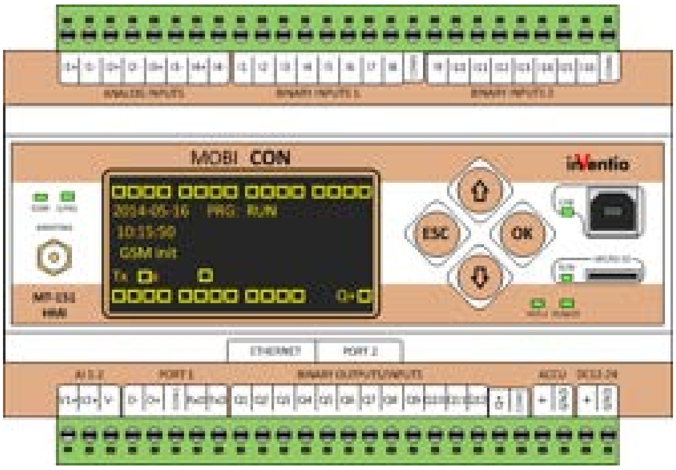

Figure 1 - Telemetry Data Logger

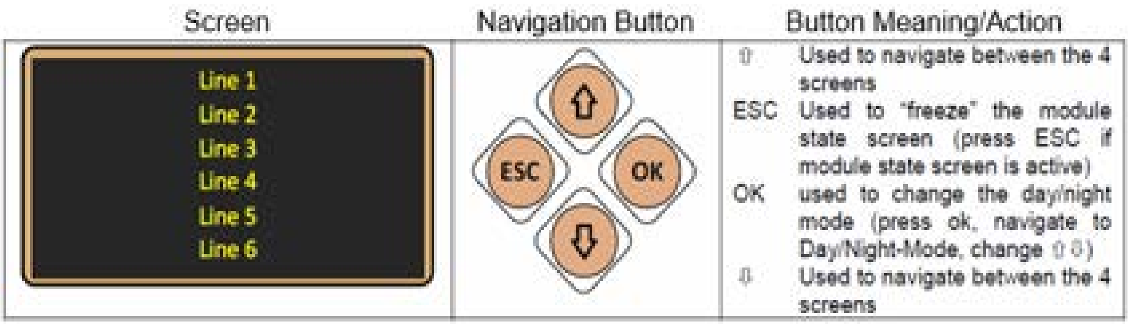

Figure 2 – Navigation Screens

1.2 The five screens are (in order):

a) Module status (Figure 2).

b) System Info.

c) Failure page 1.

d) Failure page 2.

e) Main menu (This is reached via the Module Status screen).

2. Removal of the SD Card

2.1 The main menu is accessed by pressing the “OK” button for 3 seconds when the Module State screen is displayed.

Figure 3 - Module State screen

2.2 By using the up and down arrows move the highlighted bar until “Actions” is highlighted then press the “OK” button. This “Actions” menu allows for the controlled recovery of the data stored on the SD Card.

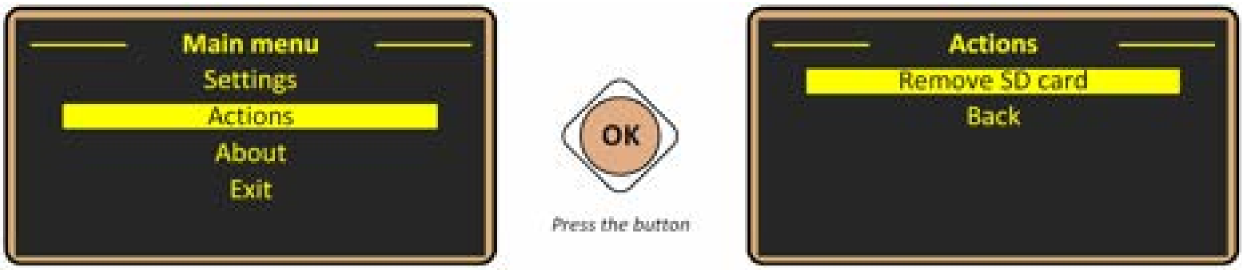

Figure 4 – Main Menu and Actions Screens

2.3 The sequence for the SD Card removal is as follows. Highlight “Remove SD Card” and press “OK”.

If you decide not to remove the card at this point highlight “No” and press “OK” this returns you back to the previous menu.

If you intend the remove the card highlight “Yes” and press “OK” this takes you to a new screen which advises you the data is being written to the SD Card and the green LED marked R/W to the left illuminates during this process.

Figure 5 – SD Card Removal Screens

2.4 Once the data transfer is completed you get a message indicating the card can be removed. Remove the card and store securely. The system continues to record data onto the internal memory.

The SD card needs to be returned to the system within 30 minutes or the data recorded internally is lost. If the card is to be out of the system for longer than 30 minutes a new SD card shall be installed.

Figure 6 – SD Card removal Screen

3. Transferring the Data to a Laptop

3.1 The SD card shall be placed into a micro-SD card adapter

Figure 7 – Micro SD Card and Adapter

3.2 The SD adapter card can now be inserted into a standard Network Rail laptop.

Figure 8 – SD Card Insertion

3.3 Click "open folder to view files using windows explorer", see Figure 9.

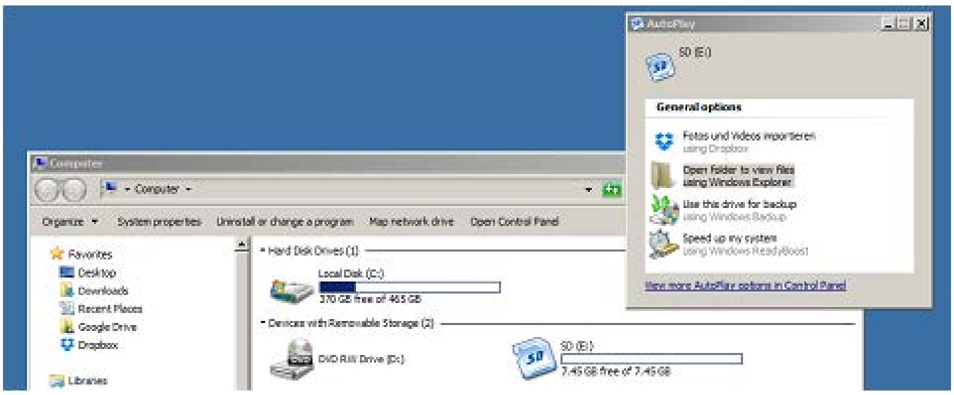

Figure 9 – Windows Explorer View

3.4 With SD card open three folders are displayed. See Figure 10.

3.5 On the laptop create a folder called c:\vamos\backup.

3.6 Copy the Log Converter and LOGFILES folders from the SD Card into the backup folder.

3.7 Safely disconnect and eject the SD card.

3.8 The SD card can now be removed from the SD adaptor and reinserted carefully into the Micro SD card slot of the data-logger. Confirm that the green R/W LED illuminates after you have reinserted the card. It can take up to 2 minutes to recognise the card. The logger can now write to the card again, when the internal memory is full.

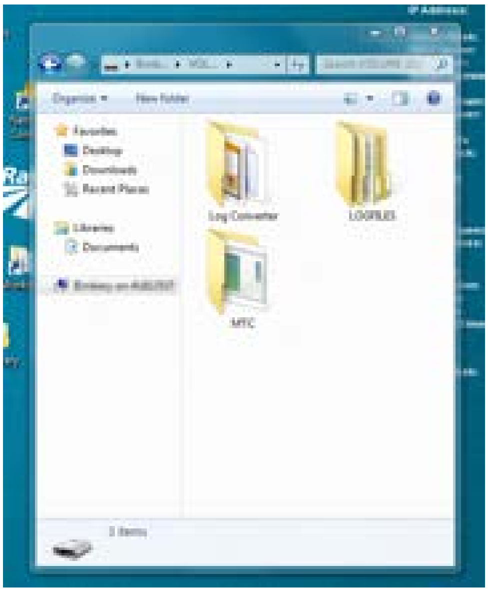

Figure 10 – SD Card Folders

4. Converting the Logger Data.

4.1 Browse to the backup directory and double click the Vamos Logfile Convertor to start it.

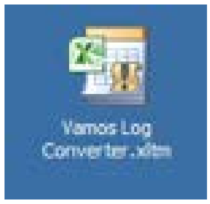

Figure 11 - Vamos Logfile Convertor Icon

4.2 Select "Convert" to convert a logfile.

Figure 12 – Converter Screen

NOTE: *If you select "Help" more information is provided about the convertor and how to use it. The "Admin" button is for people with convertor administrator privileges only.*

4.3 Open the “LOGFILES” folder it contains one file for each day.

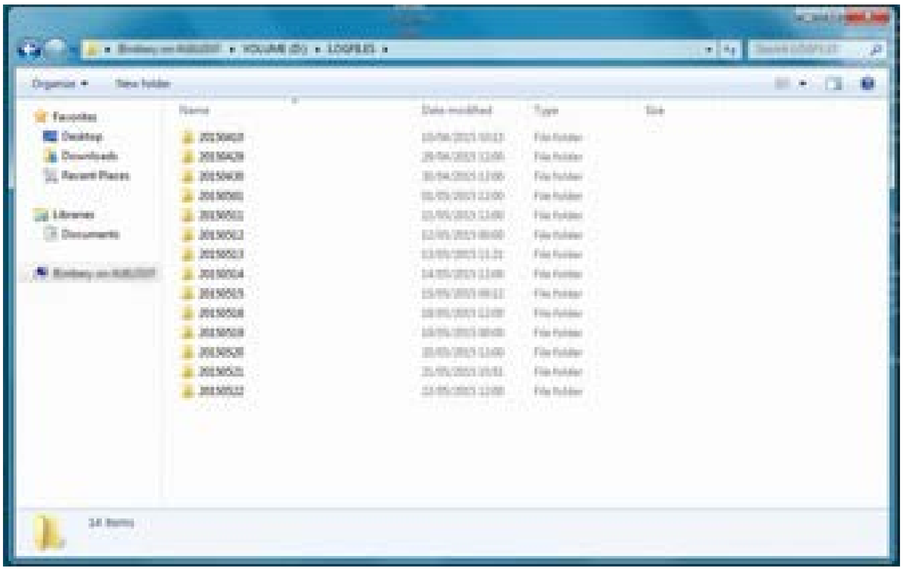

Figure 13 – Log Files Folder

4.4 Double click the file for the day you are interested in.

The file is now converted into a user-friendly spreadsheet, before allowing you to open the file, it shall be saved into the backup folder.

The file appears as shown in Table 1.

Vamos level cross Logfiles:		**Training_unit**		
Date	**Event**	**Time**	**Status**	
12/05/2015	RED aspect FAILURE	12:05:34	ON	
12/05/2015	GREEN aspect FAILURE	12:05:34	OFF

Table 1 – Day File shown in Excel

5. Understanding the Converted Log File

5.1 The top line of each file states that it is a Vamos Level Crossing Logfile and the physical location of the system.

5.2 The Vamos system only records changes of state therefore reducing the need for large amounts of memory.

5.3 The first column contains the **Date** of the entry.

5.4 The second column contains the **Event** (what has changed). Further details are shown in Section 6 - What each “Event” Means.

5.5 The third column contains the **Time** of the entry.

5.6 The fourth column contains **Status**. Either “On” or “Off”.

5.7 The fifth column is only used to indicate that the first 25 lines of data have been transferred from the previous “logfile” to assist with issues that cross the changeover boundaries.

6. What each “Event” Means

6.1 Table 2 provides the NR Rail meaning of each event to assist in the interpretation of the condensed entries found in the LOGFILES. Having a reference copy of each crossing sequence under normal circumstances can be beneficial when investigating any alleged anomalies or incidents.

Logfile event entry	**Network Rail meaning**
Strike-IN Track x (ON)	Normal direction wheel sensor strike-in Track X (wheel detected)
Strike-IN Track x (OFF)	Normal direction wheel sensor strike-in Track X (wheel no longer detected)
Strike-OUT Track x (ON)	Normal direction wheel sensor strike-out Track X (wheel detected)
Strike-OUT Track x (OFF)	Normal direction wheel sensor strike-out Track X (wheel no longer detected)
REVERSE strike-IN Track x (ON)	Reverse direction wheel sensor strike-in Track X (wheel detected)
REVERSE strike-IN Track x (OFF)	Reverse direction wheel sensor strike-in Track X (wheel no longer detected)
RED aspect (ON)	Red aspect illuminated
RED aspect (OFF)	Red aspect extinguished
RED aspect FAILURE (ON)	Red aspect failed
RED aspect FAILURE (OFF)	Red aspect fault cleared
GREEN aspect (ON)	Green aspect illuminated
GREEN aspect (OFF)	Green aspect extinguished
GREEN aspect FAILURE (ON)	Green aspect failed
GREEN aspect FAILURE (OFF)	Green aspect fault cleared
MSL System FAILURE (ON)	Miniature Stop Light System failed
MSL System FAILURE (OFF)	Miniature Stop Light System fault cleared
VaMoS System AVAILABLE	Vamos System available
Audible Warning (ON)	Audible Warning sounding
Audible Warning (OFF)	Audible Warning silenced
Audible Warning FAILURE (ON)	Audible Warning failed
Audible Warning FAILURE (OFF)	Audible Warning fault cleared
Another Train Coming (ON)	Another Train Coming audible warning sounding
Another Train Coming (OFF)	Another Train Coming audible warning silenced
DARK-Mode (ON)	System in Standby mode (Indication Post LED's Out)
DARK-Mode (OFF)	System in Normal mode (Indication Post LED's Lit)
Track x issue (ON)	Track 1 Issue (failed)
Track x issue (OFF)	Track 1 Issue (fault cleared)
On-demand Button y PRESSED (ON)	On-demand Button y pressed
On-demand Button y PRESSED (OFF)	On-demand Button released
On-demand Button FAILURE (ON)	On-demand Button failed
On-demand Button FAILURE (OFF)	On-demand Button failure cleared
System power (ON)	System power available
System INITIALIZED (ON)	System initializing
System INITIALIZED (OFF)	System initialization complete
System power (OFF)	System power off
GSM network (ON)	GSM network restored
GSM network (OFF)	GSM Network failed
RTC battery empty (ON)	RTC battery discharged
RTC battery empty (OFF)	RTC battery charging / charged
OD Parameter fault (ON)	OD Parameter failed
OD Parameter fault (OFF)	OD parameter failure recovered

Table 2 – Event Meanings

Key		
X	=	Track 1 or Track 2 (Track 1 always Up Road / Direction and Track 2 Down Road / Direction)
Y	=	On Demand button 1 or 2

Table 3 – Key to the Events Meanings Table

END

Includes:	Vamos Crossing system
Excludes:	All other Crossing systems

GENERAL

Before work is undertaken that affects the normal operation of the level crossing system, the Signaller shall be informed. Normally a possession of the equipment or a no train period is required.

1. Operational Sequence Test - No Train

1.1 Check no train is expected to enter the level crossing strike in area from any direction for the duration of this test.

1.2 Confirm the system is in “Standby Mode” (No red or green indicator LED lit).

1.3 Using a timing device, Press/touch the “On-Demand” button on one of the indication posts and start timing.

1.4 Observe that the “On-Demand” LED is extinguished, at the same time the green LEDs illuminate in both indication posts.

1.5 Check that the green LEDs are extinguished after 5 minutes.

1.6 Repeat for the other indication post.

1.7 Check the crossing returns to “Standby Mode” and the “On-Demand” red LEDs are illuminated.

2. Operational Sequence Test - One Train

2.1 Check no train is expected to enter the level crossing strike in area from any direction for the duration of tests.

2.2 Where the “On-Demand” option is fitted:

a) Confirm the system is in “Standby Mode” (No red or green indicator LED lit)

b) Press/touch the “On-Demand” button on one of the indication posts.

c) Observe that the “On-Demand” blue LED is extinguished and changes to yellow whilst touching button, at the same time the green LEDs illuminate in both indication posts.

2.3 Simulate a train “striking in” on a strike in sensor head by operating the test switches on a Strike-in evaluator board (IMC).

2.4 Observe the green LEDs on both indicator posts are extinguished and that the red LED's illuminate.

2.5 Confirm that both audible warnings sounders are working correctly.

2.6 Simulate a train "striking out" on a strike out sensor head on the same line as the "Strike in" sensor by operating the test switches on a Strike-out evaluator board (IMC).

2.7 After a short delay (3-6 seconds), Observe the indicator post LED's change from red to green.

2.8 Confirm the audible warning ceases.

2.9 Repeat steps 2.2 to 2.8 for each direction a train could approach from, including wrong direction moves.

3. Operational Sequence Test - Double Lines Second Train Approaching

3.1 Check no train is expected to enter the level crossing strike in area, from any direction for the duration of tests.

a) Confirm the system is in "Standby Mode" (No red or green indicator LED lit).

b) Press/touch the "On-Demand" button on one of the indication posts.

c) Observe that the "On-Demand" LED is extinguished, at the same time the red LEDs illuminate in both indication posts.

3.2 Simulate a train "striking in" on a strike in sensor head by operating the test switches on a Strike-in evaluator board (IMC).

3.3 Simulate a train "striking in" on a strike in sensor head mounted on 2nd line in the "opposite direction" to the first train, by operating the test switches on a Strike-in evaluator board (IMC).

3.4 Confirm that both audible warnings sounders, do not change to the second train approaching warning.

3.5 Check both indication posts continue to display a red LED.

3.6 Simulate a train "striking out" on first sensor by operating the test switches on a Strike-out evaluator board (IMC).

3.7 Confirm that both audible warnings sounders, now change to the second train approaching warning.

3.8 Check both indication posts continue to display a red LED and the warning continue to sound.

3.9 Simulate a train “striking out” on 2nd line by operating the test switches on a Strike-out evaluator board (IMC).

3.10 After a short delay (3-6 seconds), Observe the indicator post LED’s change from red to green.

3.11 Confirm the audible warning ceases.

3.12 The “On-Demand” LED’s remains extinguished until the crossing reverts to “Standby Mode”.

END

Includes:	All types of Automatic Full Barrier Crossing Locally Monitored (AFBCL)
Excludes:	All other types of Crossing

General

Liaise with the Signaller before any tests are carried out.

Check in the crossing control tables for the amber light time, red light time and any special controls that affect the automatic control sequence.

Where the word EXIT occurs, the strike out treadle shall be operated. On single lines or where bi-directional controls exist, the leaving track circuit shall also be operated.

Where directional proving controls exists the bi-directional strike out treadle shall also be operated in the correct sequence.

The following abbreviations are used in this service:

- DRL: Driver's Red Light.
- DWL: Driver's White Light.
- SPOD: Standing Person Obstacle Detector.

SERVICE A TESTS

1. Local Control Sequence

1.1 Operate the LCU to the lower position and check the following items:

a) All the amber road signals illuminate and the audible warnings commence at the same time (at the normal warbling rate).

b) After the amber time all the amber signals extinguish, all the red flashing road signals & any pedestrian lights start to flash and the crossing headlights illuminate.

c) After the red time the entrance barriers commence to lower and all the boom lamps illuminate. The entrance barriers reach their fully lowered position in 6 to 8 seconds.

d) After the entrance barriers are down the exit barriers start to lower. The exit barriers reach their fully lowered position in 6 to 8 seconds.

e) The crossing headlights, red road lights and any pedestrian lights continue to be illuminated and audible warnings continue to sound.

f) Check that all the DRLs continue to flash and the DWLs do not illuminate.

1.2 Confirm that no trains are approaching.

1.3 Operate the LCU to the raise position and check the following items:

a) All barriers start to rise at the same time and the headlights extinguish.

b) The road lights extinguish when all the barriers are above 42° from the horizontal and the audible warnings turn off.

c) The boom lights extinguish when all the barriers reach 81° from the horizontal.

d) All the barriers reach their fully raised position in less than10 seconds.

1.4 Operate the LCU to the auto position. Observe that a full lowering sequence takes place followed by a full raising sequence. Check that all DRL are flashing.

1.5 Close and lock the LCU door. Check the door cannot be locked unless the switch is in the auto position.

1.6 Check that all the DRLs are flashing.

2. Automatic Control Sequence (Crossing Area Clear)

2.1 Observe, with no train approaching, all DRLs are flashing.

2.2 Simulate an approaching train by shunting a controlling track circuit. Observe the following:

a) On double lines 10 seconds elapse before the crossing sequence commences. On single lines the sequence starts immediately.

b) All the amber road signals illuminate and the audible warnings commence at the same time (at the normal warbling rate).

c) After the amber time all the amber signals extinguish, all the red flashing road signals & any pedestrian lights start to flash and the crossing headlights illuminate.

d) After the red time the entrance barriers commence to lower, all the boom lamps illuminate and the SPOD shutters open. The entrance barriers reach their fully lowered position in 6 to 8 seconds.

e) After the entrance barriers are down the exit barriers start to lower and the SPOD shutters close. The exit barriers reach their fully lowered position in 6 to 8 seconds.

f) The crossing headlights, red road lights and any pedestrian lights continue to be illuminated and audible warnings continue to sound.

g) When all the barriers are down the driver's red light extinguishes and the DWL commences to flash for the direction where the train simulation was applied. The DRL continues for all other directions.

h) Check the sighting of the boom lamps.

2.3 Operate the exit function and remove the train simulation. Observe the following:

a) All barriers start to rise at the same time and the headlights extinguish.

b) DWL for the direction where the simulation was applied extinguishes and the DRL (if provided) commences to flash.

c) The road lights extinguish when all the barriers are above 42° from the horizontal and the audible warnings turn off.

d) The boom lights extinguish when all the barriers reach 81° from the horizontal.

e) All the barriers reach their fully raised position in less than10 seconds.

2.4 Repeat steps 2.2 and 2.3 for the opposite direction on a single line and the other direction on double lines.

3. Automatic Control Sequence (Crossing Area Occupied)

3.1 Observe, with no train approaching, all DRLs are flashing.

3.2 Place an obstruction that can be detected by a SPOD on the crossing.

3.3 Simulate an approaching train by shunting a controlling track circuit. Check the following:

a) On double lines 10 seconds elapse before the crossing sequence commences. On single lines the sequence starts immediately.

b) All the amber road signals illuminate and the audible warnings commence at the same time (at the normal warbling rate).

c) After the amber time all the amber signals extinguish, all the red flashing road signals & any pedestrian lights start to flash and the crossing headlights illuminate.

d) After 3 seconds all the amber signals extinguish, and all the red road signals and any pedestrian lights start to flash.

e) After the red time the entrance barriers commence to lower and all the boom lamps illuminate and the SPOD shutters open. The entrance barriers reach their fully lowered position in 6 to 8 seconds.

f) After the entrance barriers are down the exit barriers stay raised.

g) Remove the obstruction. Observe that the exit barriers commence to lower and the SPOD shutters close.

h) The exit barriers reach their fully lowered position in 6 to 8 seconds.

i) When all the barriers are down the driver's red light extinguishes and the DWL commences to flash for the direction where the train simulation was applied. The DRL continues for all other directions.

j) The crossing headlights, red road lights and any pedestrian lights continue to be illuminated and audible warnings continue to sound.

3.4 Operate the exit function and remove the train simulation. Observe the following:

a) All barriers start to rise at the same time and the headlights extinguish.

b) DWL for the direction where the simulation was applied extinguishes and the DRL (if provided) commences to flash.

c) The road lights extinguish when all the barriers are above 42° from the horizontal and the audible warnings turn off.

d) The boom lights extinguish when all the barriers reach 81° from the horizontal.

e) All the barriers reach their fully raised position in less than10 seconds.

4. Double Lines Second Train Approaching Sequence

4.1 Simulate a train striking in on line one as per 2.2.

4.2 Simulate a second train striking in on line two. Observe the following:

a) The barriers remain lowered.

b) The road lights and any pedestrian lights continue to flash.

c) The audible warning rate continues at the normal rate.

d) The crossing headlights continue to illuminate.

4.3 Operate the exit function and remove the simulation on line one. Observe the following:

a) The barriers remain lowered.

b) The road lights and any pedestrian lights continue to flash.

c) The audible warning rate changes to the increased rate.

d) The crossing headlights continue to illuminate.

e) The DWL for the direction of the simulation on line one extinguishes and the DRL commences to flash.

f) The DRL for the simulation on line two extinguishes and the DWL commences to flash.

4.4 Operate the exit function and remove the simulation on line two. Observe that the sequence is the same as described in 2.3.

4.5 Repeat steps 3.1 to 3.4 for a train striking in on line two first and a second train striking in on line one.

4.6 Where possible, observe the correct crossing sequence during passage of a train(s).

SERVICE B

Tests

These tests are for the full annual test of the crossing. NR/SMS/Part/D lists the indexes and references to the A4 format (with tick boxes) of these tests for the use of the person testing the crossing.

APPENDIX A - Indications

The following table lists the driver indications displayed throughout a local control and automatic sequence.

Situation	Indication
Automatic control, no train approaching, or no train simulation applied.	DRL Flashing DWL Extinguished
Crossing on operating on Local Control.	
Automatic control, train approaching or train simulation applied, all barriers down.	DRL Extinguished DWL Flashing
Barriers lowered by train simulation, DWL operating, any DWL proving contact broken, power off #	DRL Flashing DWL Extinguished

NOTES: *The DWL should only operate for the direction in which the train is approaching or the train simulation has been applied. The DRL should be operating for all other directions.*

#: Check the diagrams for the contacts in the DWL control circuit (this includes the (PO)PR function).

END

Includes:	Flex Crossing system
Excludes:	All other Crossing systems

GENERAL

Before work is undertaken that affects the normal operation of the level crossing system the Signaller shall be informed.

1. Operational Sequence Test - One Train (With Interface Signal Off)

1.1 Check no train is expected to enter the level crossing strike in area from any direction for the duration of the test.

1.2 Confirm any interface signals are showing “proceed”.

1.3 Simulate a train “striking in” on a strike in sensor head by operating the test switches on a Strike-in evaluator board (IMC). Confirm the section shows a count of 1.

1.4 Observe the green LEDs on both indicator posts are extinguished and that the red LED’s illuminate.

1.5 Check both audible warnings sounders are working correctly.

1.6 Simulate a train “striking out” on a strike out sensor head on the same line as the “strike in” sensor by operating the test switches on a strike-out evaluator board (IMC). Confirm the first section shows a count of 1.

1.7 After a short delay (3-6 seconds), observe the indicator post LED’s change from red to green.

1.8 Confirm the audible warning ceases.

1.9 Simulate a train “striking out” on a strike out sensor head of the second section on the same line as the “strike in” sensor by operating the test switches on a strike-out evaluator board (IMC). Confirm the first section shows a count of 0 and second section a count of 0.

1.10 Clauses 1.2 to 1.9 shall be repeated for each direction a train could approach from, including wrong direction moves.

2. Operational Sequence Test - Double Lines Second Train Approaching (With Interface Signal Off)

2.1 Check no train is expected to enter the level crossing strike in area from any direction for duration of test.

2.2 Confirm any interface signals are showing “proceed”.

2.3 Simulate a train “striking in” on a strike in sensor head by operating the test switches on a strike-in evaluator board (IMC).

2.4 Observe that the red LEDs illuminate in both indication posts. Check both audible warnings sounders sound.

2.5 Simulate a train “striking in” on a strike in sensor head mounted on 2nd line in the “opposite direction” to the first train by operating the test switches on a strike-in evaluator board (IMC).

2.6 Confirm that both audible warning sounders do not change to the second train approaching warning.

2.7 Check both indication posts continue to display a red LED.

2.8 Simulate a train “striking out” on first sensor by operating the test switches on a Strike out evaluator board (IMC).

2.9 Check both audible warning sounders, now change to the second train approaching warning.

2.10 Check both indication posts continue to display a red LED and the warning continues to sound.

2.11 Simulate a train “striking out” on 2nd line by operating the test switches on a strike out evaluator board (IMC).

2.12 After a short delay (3-6 seconds), observe the indicator post LED’s change from red to green.

2.13 Confirm the audible warning ceases.

3. Operational Sequence Test – One Train (With Interface Signal On)

3.1 Check no train is expected to enter the level crossing strike in area from any direction for the duration of the test.

3.2 Confirm the interface signal is at red, and has been at red, for greater than 2 minutes.

3.3 Simulate a train “striking in” on a strike in sensor head by operating the test switches on a strike-in evaluator board (IMC).

3.4 Observe the green LEDs on both indicator posts remain lit.

3.5 Clear the interface signal.

3.6 Observe the green LEDS on both indicator posts are extinguished, and the red LEDS are illuminated.

3.7 Check both the audible warning sounds are working correctly.

3.8 Observe the interface signal clears to proceed aspect, after signal regulation time (if applied, check in the control tables). Refer to record card for timer setting.

3.9 Simulate a train “striking out” on a strike out sensor head on the same line as the “strike in” sensor by operating the test switches on a strike-out evaluator board (IMC).

3.10 After a short delay (3-6 seconds), observe the indicator post LED’s change from red to green.

3.11 Confirm the audible warning ceases.

3.12 Clauses 3.1 to 3.11 shall be repeated for each interfaced signal.

END

1. Test

1.1 Using a meter, check that there is a voltage (110V AC) across terminals 23 and 24 in the T72 point machine.

If none is present:

1.2 Check the power supply to the heater:

- T2 links 1 and 2 in the Junction Box.

If a voltage is present:

1.3 Isolate the heater power supply.

1.4 Fit a strap across terminals 23 and 25 in the T72 point machine.

This bypasses the thermostat.

1.5 Reinstate the heater power supply and using a meter check that there is a voltage across the heater terminals 24 and 25 in the T72 point machine.

If the heater fails to operate, the heater is faulty. Replace this as part of corrective maintenance.

1.6 Remove the strap fitted across terminals 23 and 25 in the T72 point machine.

END

High voltages can be present. The appropriate precautions for working on high voltage equipment shall be implemented and observed (see NR/SMS/PartC/EL00 (Electrical Equipment General).

This test shall not be performed if there is an active earth fault at the PL/DPL. Inform your SM(S) and arrange remedial work.

The test shall be performed on at least one output on each (FIU) Field Isolation Unit in each subrack.

Removing the back plate of the subrack provides access to the 'U-Links' which are used for this test.

Each 'U-Link' is provided with a 'test hole' in its insulation to enable the circuit to be tested without the need to partially withdraw the link thereby risking circuit interruption.

Test Equipment

A calibrated resistance decade box with 'flying' leads (Details are in NR/SMS/Appendix/02).

1. Peripheral Post

Remove the back plates from all the FIU subracks.

1.1 Connect one of the 'flying leads' to the Test Earth.

1.2 Set the decade box to 900kΩ ('less than 1MΩ test').

1.3 Check that the person monitoring the SIM PC and the MOT is in position and is monitoring the correct CNT diagnostic field on the OLD screen.

1.4 Starting from the left, locate the first FIU unit fitted in the subrack.

1.5 Touch the end of the second 'flying lead' on to the test point on any one of the 'U-Links' fitted at the back of the selected FIU unit.

A Critical Alarm shall be registered on the MOT. If not, the system is faulty, and your SM(S) shall be informed immediately, rectification of the problem must be undertaken within 2 days.

1.6 Repeat the test with the decade box set to 90kΩ ('less than 100kΩ test').

1.7 Record the details of the circuits tested and the test results.

1.8 Repeat the above procedure for all of the FIU subracks within the PL/DPL.

END

AC Leakage Test

An AC leakage test shall be carried out on exposed metallic parts after each service.

For further information refer to the GraphXMaster Service Manual - section 2.3 General Guidelines – AC Leakage Test – Cold Check.

Test Equipment

- An Insulation Tester set to 500V DC
- An IEC free test socket with a lead connected to the power and neutral pins.

1. Cold Check

1.1 Check that the projector is switched off and the AC power cable has been removed from the power supply.

1.2 Plug the projector power plug into IEC test socket and connect the lead of IEC test socket into insulation tester.

1.3 Switch the projector AC switch to on.

1.4 Touch other lead of insulation tester on each exposed metallic part. Check that the resistance is >4MΩ

Pay particular attention to any exposed metal part having a return path to the chassis.

If the resistance is below this value, the projector shall be isolated and reported as a corrective maintenance item. The projector shall only be returned to service if the test result is satisfactory.

1.5 Switch the projector off and remove the projector power plug from IEC test socket.

END

There is no provision for a maintenance control to prevent a release being given for the section under test. A safe system of work shall be implemented in liaison with the Signaller.

1. Test

1.1 Obtain the Signaller's permission to test the apparatus.

1.2 Check that the TRAFFIC indicator is illuminated.

1.3 Check that the PATROL push button function is inoperative with the Normal/Operate keyswitch in the NORMAL position.

1.4 Check that the Normal/Operate keyswitch cannot be operated without its unique key.

1.5 Arrange a release with the Signaller and insert the key and turn the Normal/Operate keyswitch to the OPERATE position.

1.6 Check that the key is retained in keyswitch.

1.7 Press the button marked PATROL and Check that the TRAFFIC indicator extinguishes and the PATROL indicator illuminates.

1.8 Confirm with the Signaller that the delimited section is in PATROL mode.

e.g. signal 203 to signal 204.

1.9 Turn the Normal/Operate keyswitch to the NORMAL position and Check that the PATROL indicator remains illuminated.

1.10 Request the Signaller to cancel the release and confirm that the section remains in PATROL mode The PATROL mode indicator remains illuminated.

1.11 Turn the Normal/Operate keyswitch to the OPERATE position and Press the button marked TRAFFIC.

1.12 Check that the PATROL indicator extinguishes and the TRAFFIC indicator illuminates.

1.13 Confirm with the Signaller that the section has been returned to TRAFFIC mode.

1.14 Turn the Normal/Operate keyswitch to the NORMAL position and remove the key.

1.15 If applicable, repeat 1.1 to 1.14 for any adjacent section(s).

1.16 Repeat 1.1 to 1.15 at the other associated control position(s).

END

High voltages can be present. The appropriate precautions for working on high voltage equipment shall be implemented and observed.

The particular equipment being tested shall be electrically isolated by removing the appropriate fuse(s).

Before disconnecting any wiring from the RK170, the voltage on A1, A2, M+, M-, 6 and 7 with respect to earth shall be measured and if greater than 25 volts (AC or DC) shall be rectified as corrective maintenance.

TESTS

1. Function Test

1.1 Agree with the Signaller the identity of the power supply to be tested and the equipment to be affected.

1.2 Record the details of that particular power supply.

1.3 Isolate the ELD and associated RK170 unit by removing the associated fuse(s).

1.4 Check the circuit is isolated by measuring the voltage on A1, A2, M+, M-, 6 and 7 with respect to earth).

If the voltage is greater than 25 volts (ac or dc) go to 1.5 otherwise go to 1.6.

Check the correct fuse(s) have been removed before proceeding

1.5 Disconnect and remove the output from the RK170 (terminals 6 and 7) to the trend controller.

1.6 Connect the auxiliary current source to the output wiring to the trend controller.

1.7 Increase the auxiliary current in incremental steps from 4.1mA to 20mA. (See Table1):

RK170 Output (mA)	**Total System Insulation Resistance (kOhm)**	**RCM ‘Insulation Monitoring’ Screen Status**
4.100	19080	(Green) OK
5.455	1200	
5.570	1103	
5.641	1050	
5.710	1003	
5.795	950	(Amber) WARNING
5.880	901	
6.087	800	
12.00	120	
12.350	110	
12.550	105	
12.730	100	(Red) CRITICAL
12.950	95	
13.150	90	
13.600	80	
20.00	0	

Table 1 – Resistance Value (1)

1.8 At each incremental step:

Record the resistance value (kOhm) and Insulation status displayed on the maintenance desk insulation monitoring screen.

1.9 At each alarm transition threshold:

Check the insulation status changes from:

a) ‘OK’ to Warning’ at 1000kOhm.

b) ‘Warning’ to ‘Critical’ at 100kOhm.

If the measured value deviates by more than ±5% from the designated alarm setting 100kOhm (105kOhm – 95kOhm) or 1000kOhm (1050kOhm – 950kOhm) the SM(S) shall be notified.

1.10 When the 20mA increment is reached:

Repeat the test, using the same incremental steps in reverse order, reducing the current from 20mA to 4.1mA. (See table2).

1.11 At each incremental step:

Record the Resistance value (kOhm) and Insulation status displayed on the Maintenance Desk Insulation Monitoring screen.

1.12 At each alarm transition threshold:

Check the insulation status changes from: ‘Critical’ to ‘Warning’ at 100kOhm ‘Warning’ to ‘OK’ at 1000kOhm.

If the measured value deviates by more than ±5% from the designated alarm setting 100kOhm (105kOhm – 95kOhm) or 1000kOhm (1050kOhm – 950kOhm) the SM(S) shall be notified.

RK170 Output (mA)	Total System Insulation Resistance (kOhm)	RCM ‘Insulation Monitoring’ Screen Status
20.00	0	(Green) OK
13.600	80	
13.150	90	
12.950	95	
12.730	100	
12.550	105	(Amber) WARNING
12.350	110	
12.00	120	
6.087	800	
5.880	901	
5.795	950	
5.710	1003	(Red) CRITICAL
5.641	1050	
5.570	1103	
5.455	1200	
4.100	19080	

Table 2 - Resistance Value (2)

1.13 Remove the test equipment.

1.14 Reconnect the trend controller to the RK170. (Terminals 6 and 7).

1.15 Replace all fuses.

1.16 Check the ELD LCD is displaying the resistance value. (The value shall be greater than 1000kOhm).

1.17 Check the maintenance desk insulation monitoring screen is displaying resistance values greater than 1000kOhm and the Insulation status is (green) ‘OK’.

1.18 Record details and test results.

END

There is no provision for a maintenance control to prevent a release being given for the section under test. A safe system of work shall be implemented in liaison with the Signaller.

1. Test

1.1 Obtain the signaller’s permission to test the apparatus.

1.2 Check that the TRAFFIC indicator is illuminated.

1.3 Check that the PATROL push button function is inoperative with the Normal/Operate keyswitch in the NORMAL position.

1.4 Check that the Normal/Operate keyswitch cannot be operated without its unique key.

1.5 Arrange a release with the signaller and insert the key and turn the Normal/Operate keyswitch to the OPERATE position.

1.6 Check that the key is retained in keyswitch.

1.7 Press the button marked PATROL and check that the TRAFFIC indicator extinguishes and the PATROL indicator illuminates.

1.8 Confirm with the Signaller that the delimited section is in PATROL mode. e.g. signal 203 to signal 204.

1.9 Turn the Normal/Operate keyswitch to the NORMAL position and check that the PATROL indicator remains illuminated.

1.10 Request the signaller to cancel the release and confirm that the section remains in PATROL mode The PATROL mode indicator remains illuminated.

1.11 Turn the Normal/Operate keyswitch to the OPERATE position and press the button marked TRAFFIC.

1.12 Check that the PATROL indicator extinguishes and the TRAFFIC indicator illuminates.

1.13 Confirm with the Signaller that the section has been returned to TRAFFIC mode.

1.14 Turn the Normal/Operate keyswitch to the NORMAL position and remove the key.

1.15 If applicable, repeat 1.1 to 1.15 for any adjacent section(s).

1.16 Repeat 1.1 to 1.16 at the other associated control position(s).

END

General

Treadles shall be set and checked using one of the following methods:

a) Line/bob-weights and associated plastic gauge.

b) Extendable bar treadle gauge.

The metal treadle arm gauge shall not be used for this task.

Record all results on the Record Card.

1. Treadle Gauging - Method One (Line and Bob)

Gauge Set-up

A line shall be attached to the plumb weights that allows for the weights to suspend the line over both running rails. See Figure 1.

Gauge Test

The plastic gauge can then be used with the notched end against the line and the stepped side against the treadle arm. The height below and from the rail can then be read from the scale. See Figure 2 and Table 1.

Figure 1 - Use of the Treadle Gauge

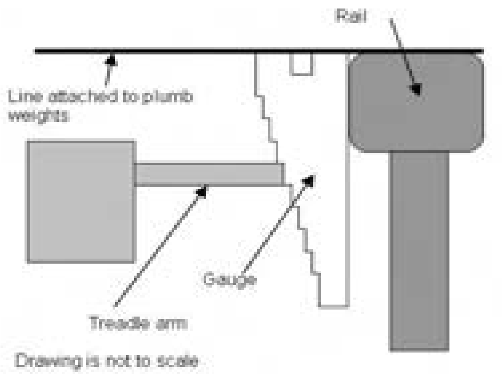

Figure 2 - Treadle Gauging Equipment

Treadle Type	Height Below Rail Level (H)	Distance From Running Edge of Rail (X)
69	16mm (±1mm)	10mm (+2mm or -5mm)

Table 1 - Treadle height and arm limits

2. Treadle Gauging - Method Two (Integrated Gauge)

Gauge Set-up

2.1 Place one end of the new treadle gauge on the rail and release the lock nut in the centre, extend the rod until the gauge reaches the opposite rail.

2.2 Check that both measuring ends are undamaged, in the correct position and correspond.

2.3 Hand tighten the centre release lock nut on the rod and check that both ends are positioned correctly on the rail. The gauge should be allowed to move freely without stalling or stuttering, see Figure 3.

Figure 3 – Using the Gauge

Gauging Test

<u>The 5mm Check - Inner running edge of the rail & the treadle arm.</u>

2.4 Place the gauge with the 5mm section in front of the arm and offer / move the gauge towards the treadle arm.

The 5mm section should pass through the gap.

2.5 Note if the gap is smaller, then the treadle arm needs to be adjusted, after treadle adjustment, repeat this check.

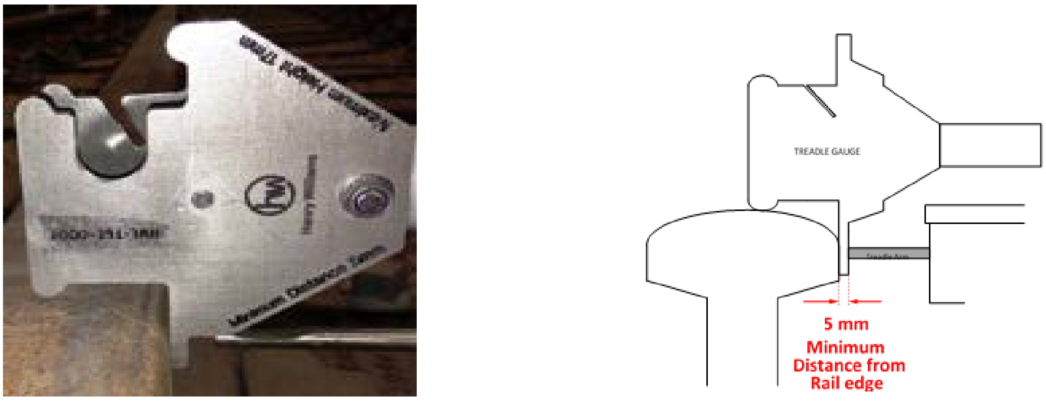

Figure 4 – 5mm Check

<u>The 12mm Check - Inner running edge of the rail & the treadle arm.</u>

2.6 Place the gauge with the 12mm section in front of the arm and offer / move the gauge towards the treadle arm.

The 12mm section of the gauge should only just pass through the gap touching the trip arm.

2.7 If the gap is greater than 12mm then the treadle arm, needs to be adjusted, after treadle adjustment, repeat this check.

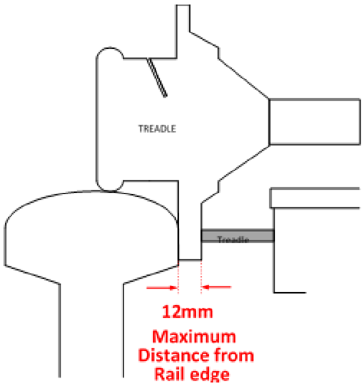

Figure 5 – 12mm Check

NOTE: *Caution should be taken to prevent an operation of the treadle arm when completing this check.*

<u>The 15mm Check - Measuring the Height of the treadle.</u>

2.8 Place the gauge with the 15mm section in front of the arm and offer / move the gauge towards the treadle arm.

The gauge should just pass over the treadle arm.

2.9 If the 15mm gauge fails to pass over the treadle arm, then the treadle height needs to be adjusted, after treadle adjustment, repeat this check

NOTE: *Caution should be taken to prevent an operation of the treadle arm when completing this check.*

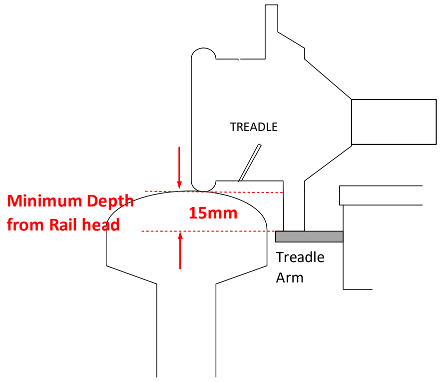

Figure 6 - 15mm Check

<u>17mm Check - Measuring the Height of the treadle.</u>

2.10 Place the gauge with the 17mm section of the gauge in front of the arm and offer / move the gauge towards the treadle arm.

The gauge should JUST TOUCH the top of the trip arm.

2.11 If the 17mm gauge fails, then the treadle height needs to be adjusted. After treadle adjustment, repeat this check.

This is the Optimum arm height setting for reliability and is important that this is achieved

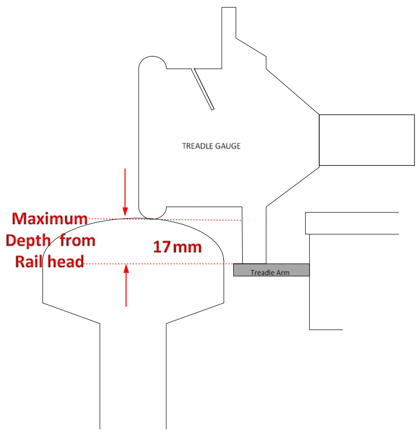

Figure 7 - 17mm Check

NOTE: *Caution should be taken to prevent an operation of the treadle arm when completing this check.*

Treadle Arm Wear Gauging Check.

The Integrated Treadle Gauge has two arm wear measurement slots within the gauge, these are uniquely identified and are used to indicate arm wear of over 75% (exceeding 2.6mm wear) and over 100% (exceeding 3.5mm wear).

This enables the Technician to report to SM(S) the arm wear condition at each maintenance visit and enables the timely planning of Treadle replacement.

Trip Arm Wear Check

2.12 Select the 75% wear gauge, align the gauge slot with the Treadle Trip Arm and slide the gauge across the worn area of the trip arm horizontally (approximately 10mm from end of trip arm).

If the wear exceeds the 75% wear gauge, repeat with the 100% wear gauge and record the reading.

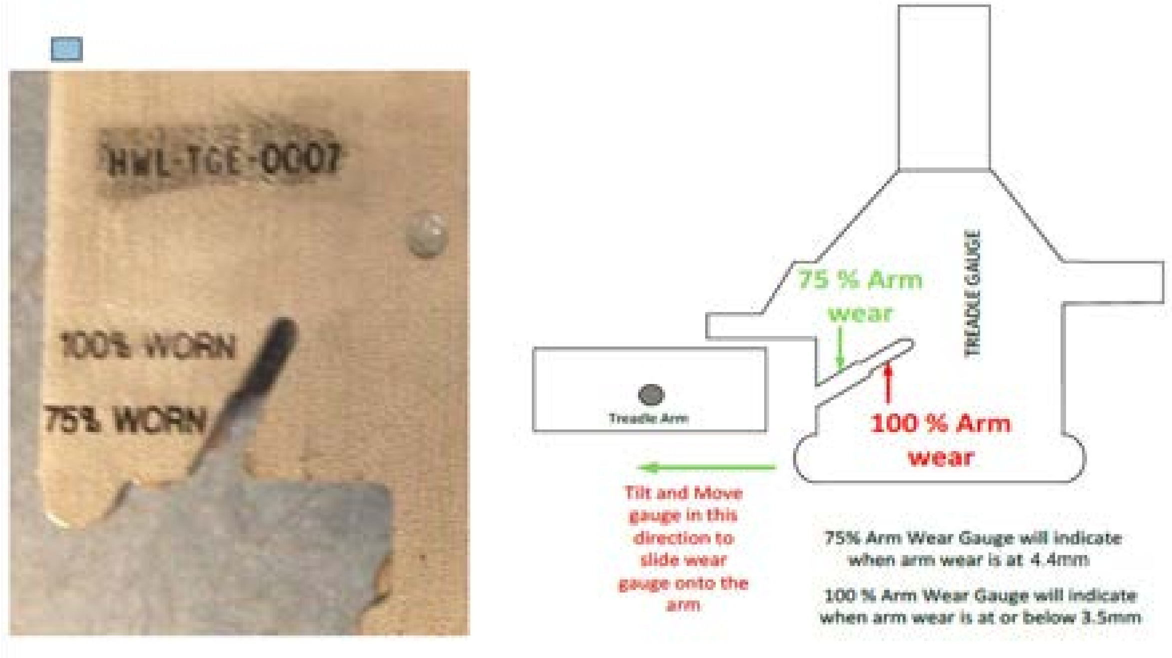

Figure 8 - Trip Arm Wear Check

2.13 Technicians shall inform SM(S) when arm wear has reached the 75% worn level, Treadles which are found to have 100% arm wear shall be reported immediately and replacement planned in as soon as possible.

2.14 Sites which have accelerated arm wear, shall have the arm heights re-checked for compliance with this guide.

END

Includes:	For EPOS Units - Hot Axle Box Detector (HABD)
Excludes:	All other types HABD systems

1. General

1.1 Manual post calibration is required in the following cases:

a) After cleaning the optical components.

b) After installing a new EPOS unit.

1.2 "Manual post calibration" creates a new "current characteristic", which immediately takes the current attenuation characteristics (e.g. changes due to cleaning) of the measuring system into consideration.

NOTE: *The passage of an actual train will interrupt the Manual Post Calibration Test.*

2. Manual Calibration

2.1 To carry out a "manual calibration" complete the following steps:

a) Launch the "Satellite Management UI" application.

b) Click on "Calibration" in the "Satellite Management UI" menu bar.

2.2 The following dropdown menu appears.

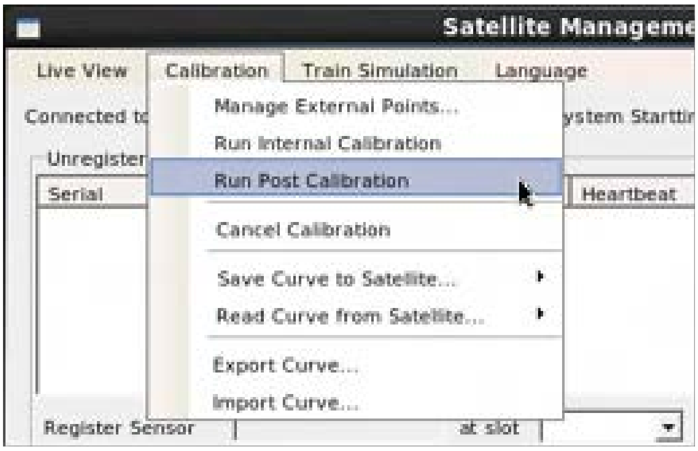

Figure 1 - Dropdown menu “Calibration" – item “Run Post Calibration”

2.3 Click the "Run Post Calibration" menu.

The FUES-EPOS system starts post calibration for all measuring points at the same time.

2.4 A log window opens, in which you can monitor the calibration process. See Figure 2.

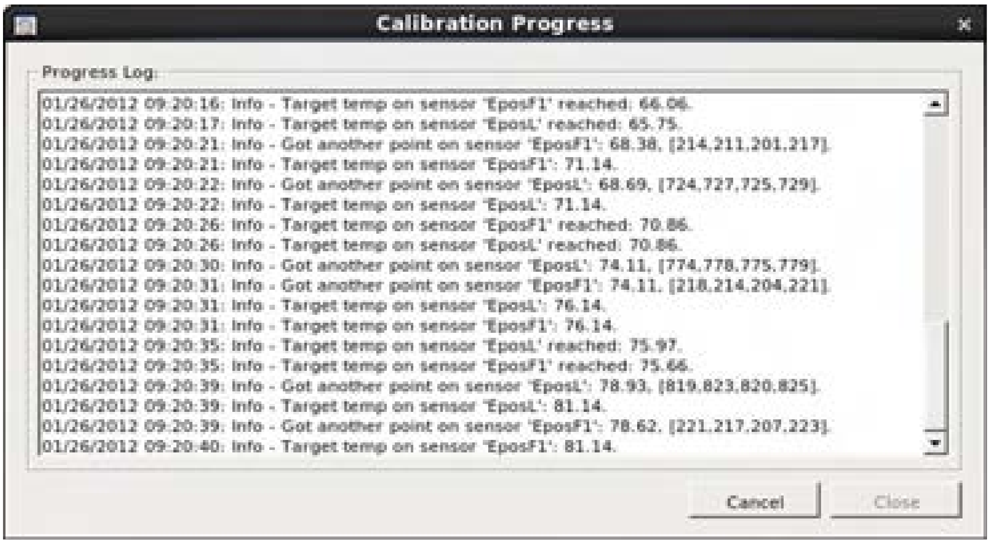

Figure 2 - Log window after starting post calibration

2.5 The internal calibration process has been successfully completed when event logging stops and the last line confirms successful calibration with the following message: New calibration curve ready. See Figure 3.

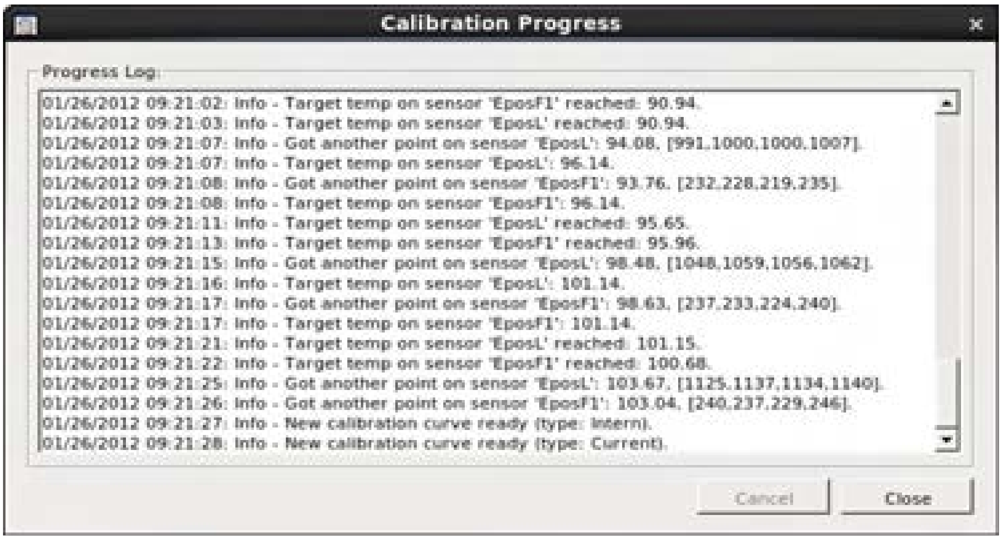

Figure 3 - Log window after completing post calibration

2.6 Close the log window by clicking the <Close> button. This completes "manual post calibration".

END

Includes:	For RSR123 Sensors fitted on Hot Axle Box Detector (HABD)
Excludes:	All other types of RSR123 Sensors fitted on other systems

1. Occupancy Detection Capability Test - Using PB200 Plate

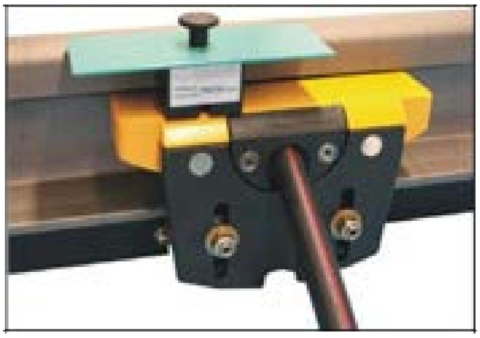

Figure 1 - PB200 above System 1

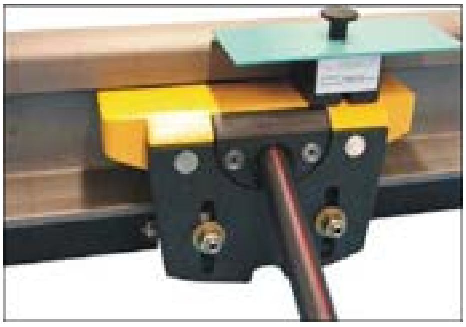

Figure 2 – PB200 above System 2

1.1 Carry out the following:

a) Place the PB200 testing plate above the system to be tested as shown in Figure 1 and check the SP board is indicating occupancy.

b) Move the PB200 to the position shown in Figure 2 and check the SP board is indicating occupancy.

c) Remove the PB200 testing plate.

1.2 If the SP board fails to indicate occupancy, carry out NR/SMS/PartB/Test/184 (EPOS – RSR123 Wheel Sensor Voltage Adjustment), followed by repeating this test.

END

Includes:	EPOS HABD
Excludes:	All other HABD Systems

1. Verifying the Measuring Precision

1.1 Run the train simulation (measurement) as follows:

a) Switch on the heat source.

b) Set the corresponding temperature value on the heat source control panel.

c) Position the heat source at the EPOS unit to be verified.

d) Launch the "Satellite Management UI" application.

e) Click the "Train Simulation" menu item.

f) The dropdown menu shown in Figure 1 appears.

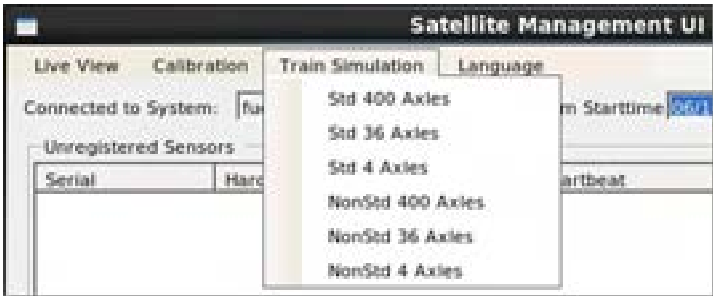

Figure 1 - Drop-down menu "Train Simulation"

g) You can run the train simulations shown in this menu, See Figure 2.

- The wheel sensor signals are simulated by the software.
- The shutters are opened.

Menu item	Function
Std 400 Axles	Train simulation in standard direction with 400 axles at 60 km/h
Std 36 Axles	Train simulation in standard direction with 36 axles at 360 km/h
Std 4 Axles	Train simulation in standard direction with 4 axles at 120 km/h
Non Std 400 Axles	Train simulation in non-standard direction with 400 axles at 60 km/h
Non Std 36 Axles	Train simulation in non-standard direction with 36 axles at 360 km/h
Non Std 4 Axles	Train simulation in non-standard direction with 4 axles at 120 km/h

Figure 2 – Simulation Options

NOTE: *These train simulations can also be run by pressing buttons on the control and evaluation unit's SP board.*

1.2 When the heat source has reached a steady target temperature, run any train simulation via the dropdown menu or the buttons on the IC board.

The FUES-EPOS system simulates a train passage. The shutters off the EPOS units open and the system records the temperature of the heat source.

1.3 We recommend verifying measuring accuracy at the following temperature values:

Measuring position	Temperature [°C]
HBD	85
HWD	300

Table 1 – Temperature Values

2. Checking the Measuring Results

2.1 Open the graphical user interface TIS GUI on the desktop of the FUES-EPOS system.

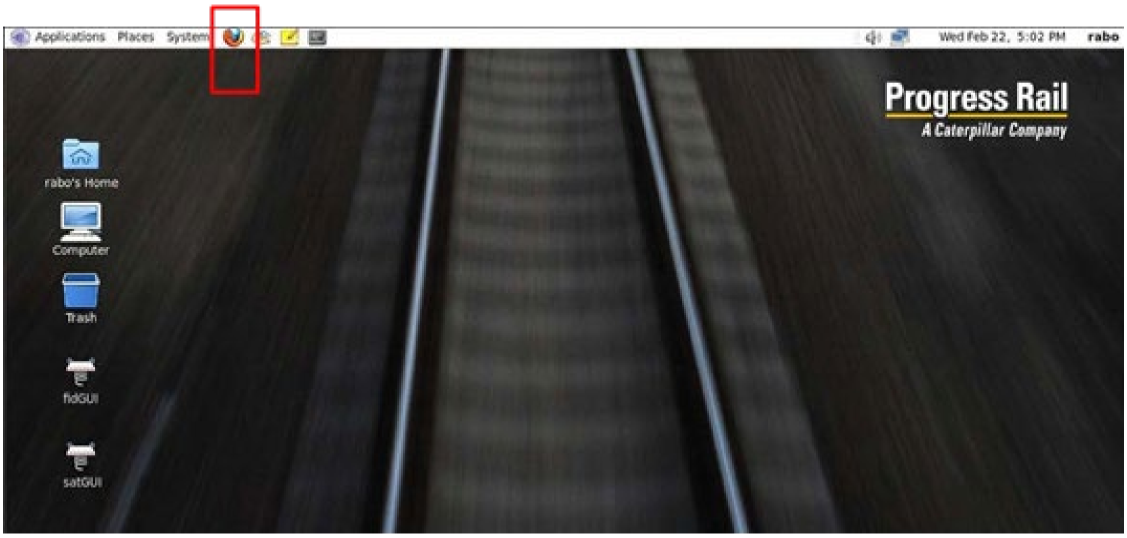

Figure 3 - FUES-EPOS system desktop (example)

NOTE: *Quick start icon for the web browser for opening the TIS GUI shown in the red box*

2.2 Click on the quick start icon for the web browser to open the TIS GUI The TIS GUI login window appears.

2.3 Enter the username and password.

The TIS GUI start window appears.

2.4 Click the Train ID button in the Last Train area below the navigation menu (see Figure 4, circled in red).

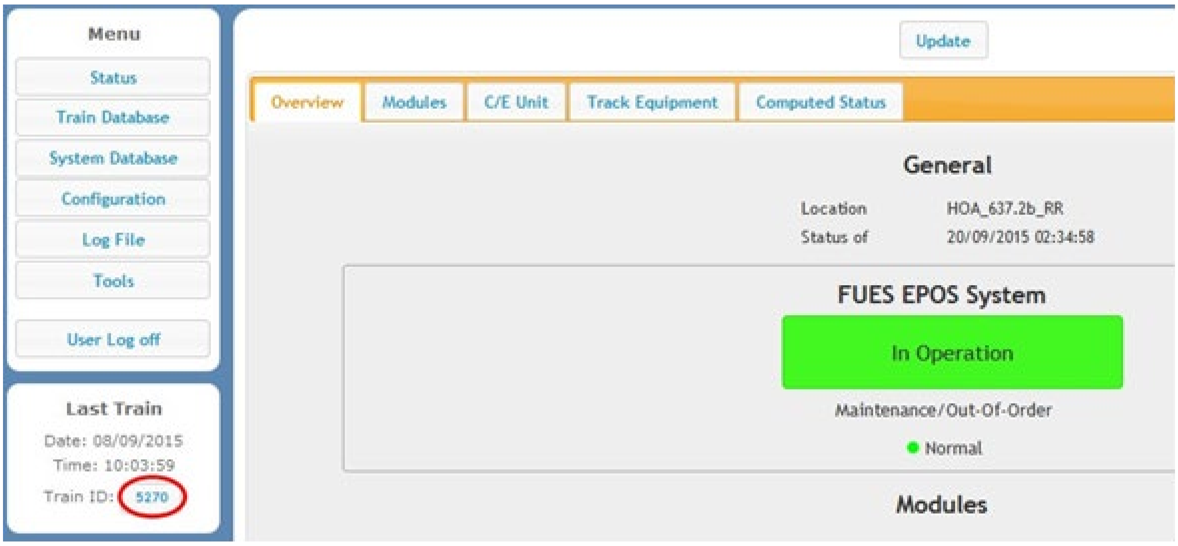

Figure 4 - Selecting the last train in the "Train selection" tab

2.5 This opens the tabs with the corresponding train data.

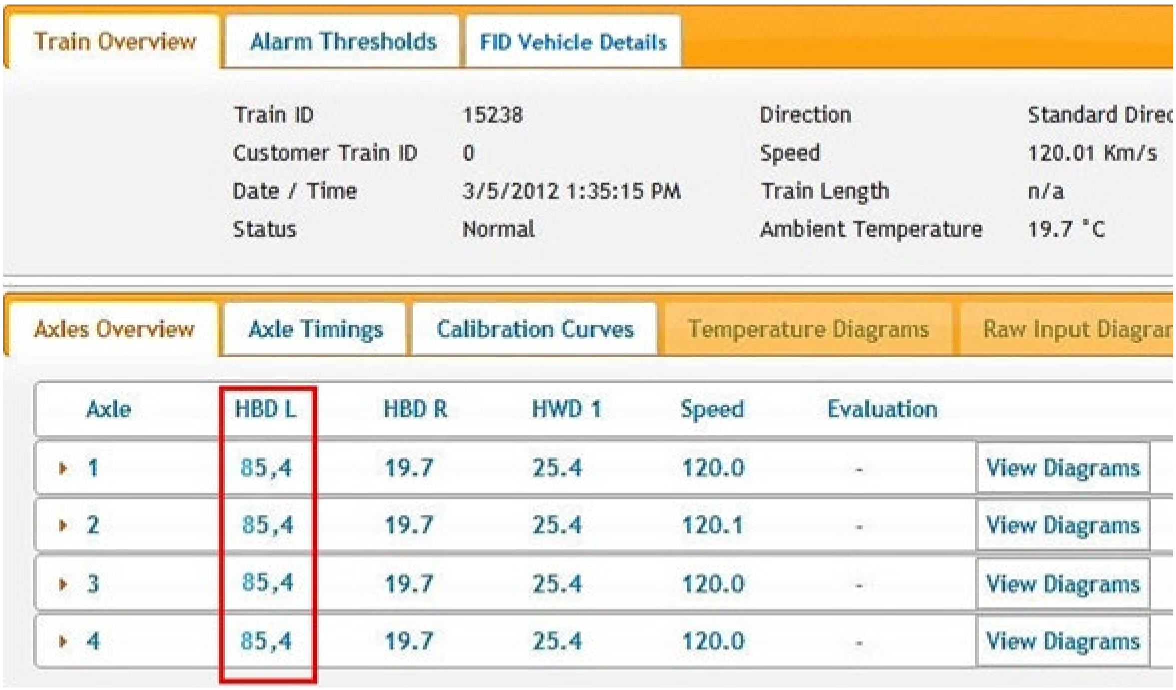

Figure 5 - Reading off the measured temperature values in the axle overview (HBD-L as an example)

2.6 Read off the temperatures measured for the selected measuring system in the axle data of the simulated train (see Figure 5).

2.7 Enter the average temperature value in the corresponding log.

You can use the following documents for this:

a) Document 5500219 "On-site testing (SAT)".

b) Document 5500220 "Factory testing (FAT)".

c) Document 5500222 "Maintenance Schedule/Record".

2.8 Check whether the defined tolerances are observed.

The following defaults apply:

Measuring position	Temperature
HBD	85 °C ± 3 C
HWD	300 °C ± 10 C

Table 2 – Temperature Tolerances

2.9 Repeat the measuring precision verification for all installed EPOS units.

2.10 If the measuring precision of an EPOS unit is outside of the defined tolerances carry out NR/SMS/PartB/Test/183 (EPOS – Basic Calibration).

END

Includes:	EPOS HABD
Excludes:	All other HABD Systems

1. General

1.1 If deviations outside of tolerance are determined while verifying measuring precision (e.g., during annual maintenance a "Basic Calibration" shall be performed.

Basic calibration gives you the ability to adjust the measuring system on the EPOS unit in question to changes that cannot be adequately compensated for by automatic post basic calibration (e.g. caused by irreversible soiling, scratches, or aging effects).

2. Performing "external calibration"

2.1 Click on "Calibration" in the "Satellite Management UI" menu bar.

The following dropdown menu appears, see Figure 1.

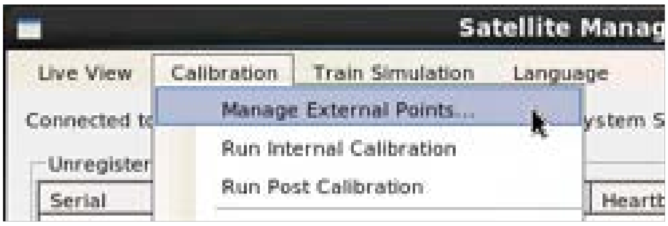

Figure 1 - Dropdown menu "Calibration" – item "Manage External Points"

2.2 Click the "Manage External Points" menu item.

This opens the "External Calibration Manager" dialogue window (see Figure 2)

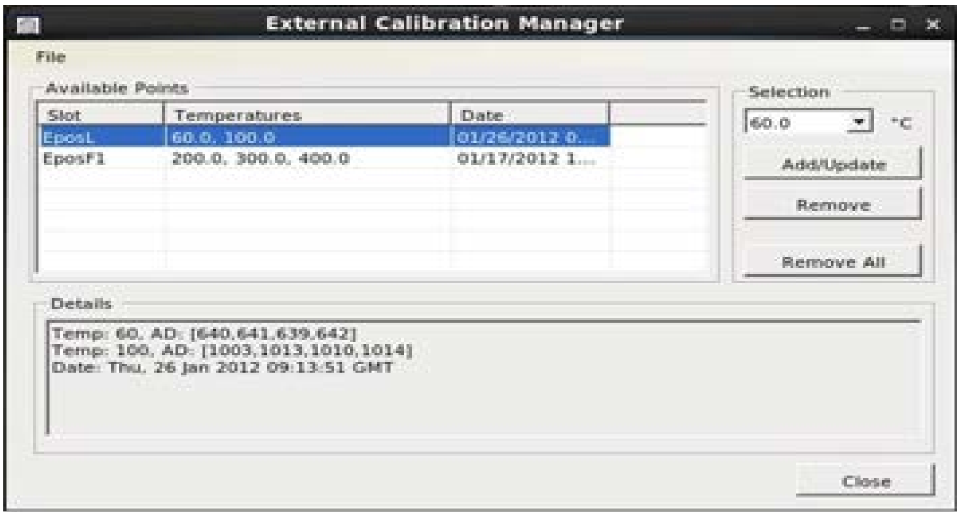

Figure 2 - "External Calibration Manager" dialogue window

2.3 In the list of "Available Points" select the measuring system (EPOS unit) for which you will be performing calibration. See Figure 2.

2.4 Select the temperature value in the dropdown list.

NOTE: *You only need to perform basic calibration of EPOS units whose measuring precision is outside of the tolerance.*

If multiple EPOS units are affected, we recommend a specific approach to choosing the calibration point order in line with Table 1.

NOTE: *that cooling and heating the calibration radiator takes a considerable amount of time, and that the suggested measuring points have proved useful in basic calibration.*

Measuring position	Temperature [°C]
HBD-L	60
HBD-R	60
HBD-L	100
HBD-R	100
HWD1	200
HWD2	200
HWD1	300
HWD2	300
HWD1	400
HWD2	400

Table 1 - Recommended order of measuring systems for external calibration

2.5 Switch on the calibration radiator(s).

2.6 Set the corresponding temperature value on the calibration radiator control panel.

2.7 Position the calibration radiator at the EPOS unit to be calibrated.

2.8 When the calibration radiator has reached a steady target temperature, click the "Add/Update" button to start the measuring process.

The shutter on the corresponding EPOS unit opens and the system records the digital values measured. The measuring process is complete when the shutter closes again.

2.9 Repeat this process for all required calibration points.

After completing the last required calibration point, the external calibration is complete.

3. Performing "internal calibration"

3.1 Click on "Internal Calibration" in the "Satellite Management UI" menu bar.

The dropdown menu shown in Figure 3 appears.

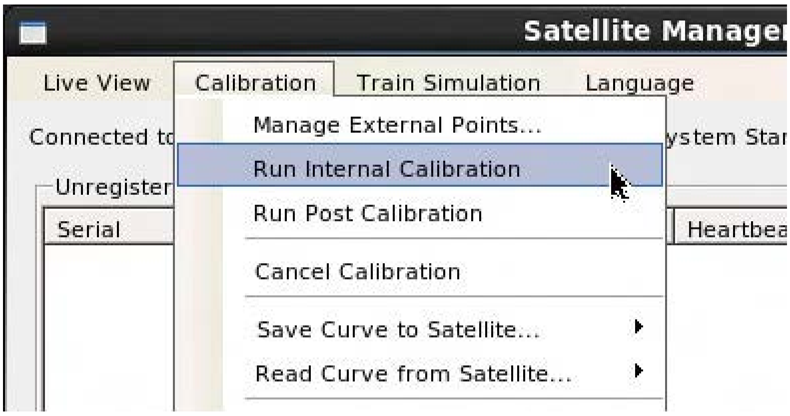

Figure 3 - Dropdown menu "Calibration" – item "Run Internal Calibration"

3.2 Click the "Run Internal Calibration" menu.

A selection window opens, see Figure 4.

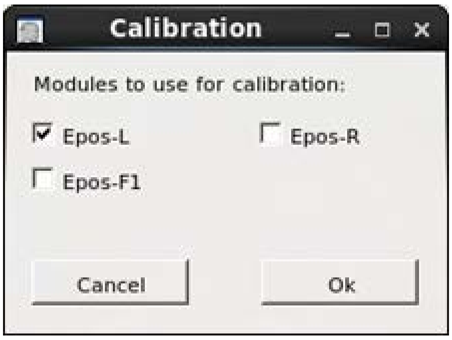

Figure 4 - Selection window

3.3 Select the measuring system(s) to be calibrated using ☑.

3.4 Click the <OK> button to start the internal calibration process.

The FUES-EPOS system starts internal calibration for the selected measuring system(s)

This opens a Log window (see Figure 5), in which you can monitor the calibration process.

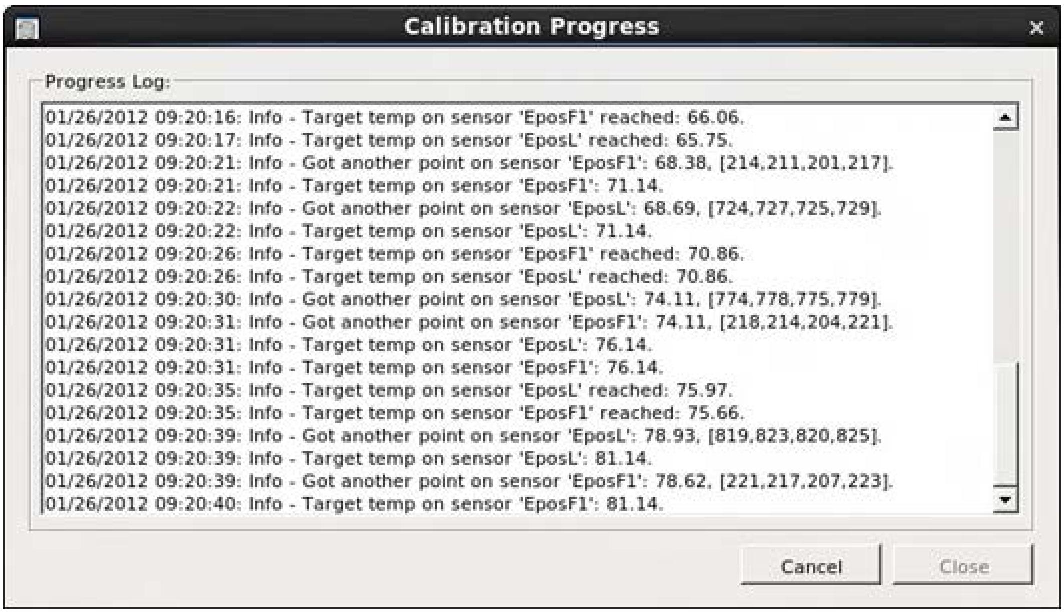

Figure 5 - Log window after starting internal calibration

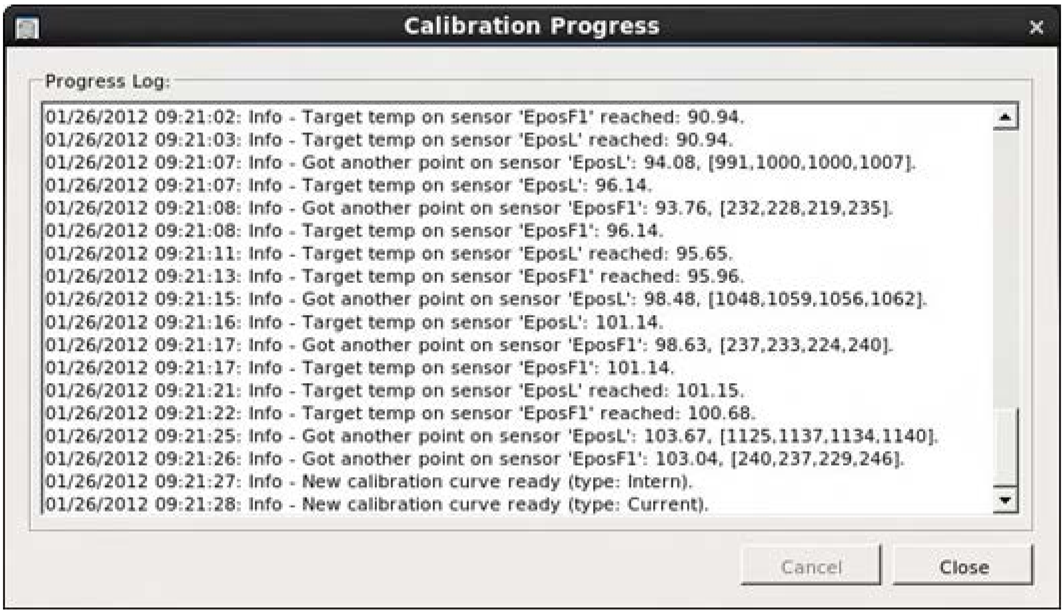

Figure 6 - Log window after completing internal calibration

The internal calibration process has been successfully completed when event logging stops and the last line confirms successful calibration with the following message: **New calibration curve ready,** see the last line of the screen shown in Figure 6.

3.5 Close the log window by clicking the <Close> button.

3.6 This completes the internal calibration.

4. Completing basic calibration

4.1 After completing internal calibration, the system computes the "basic characteristic" from the external and internal calibration data; this forms the basis for temperature measurements.

4.2 The basic calibration data are automatically stored in the FUES-EPOS system database where they are immediately available for the next train run.

Additionally, the basic calibration data in the newly calibrated EPOS unit shall be stored in the EPOS's Units memory. This means that the calibration data of this EPOS unit are available for use at other locations.

5. Storing the calibration data on an EPOS unit

5.1 Click on "Internal Calibration" in the "Satellite Management UI" menu bar.

The corresponding dropdown menu appears.

5.2 Move the cursor to the "Save Curve to Satellite" menu item, but do not press the mouse button.

Another dropdown menu appears where you can select the measuring system as shown in Figure 7.

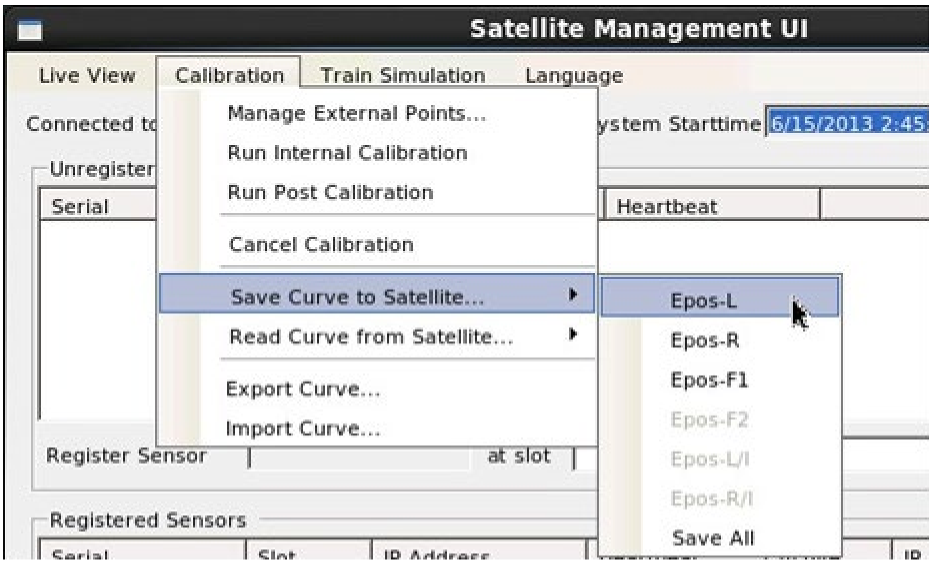

Figure 7 - Dropdown menu "Calibration" item "Save Curve to Satellite"

5.3 Move the cursor to the desired measuring system and left click.

The system starts to transfer the calibration data. This opens a log window where you can monitor the data transfer progress (see Figure 8 and Figure 9).

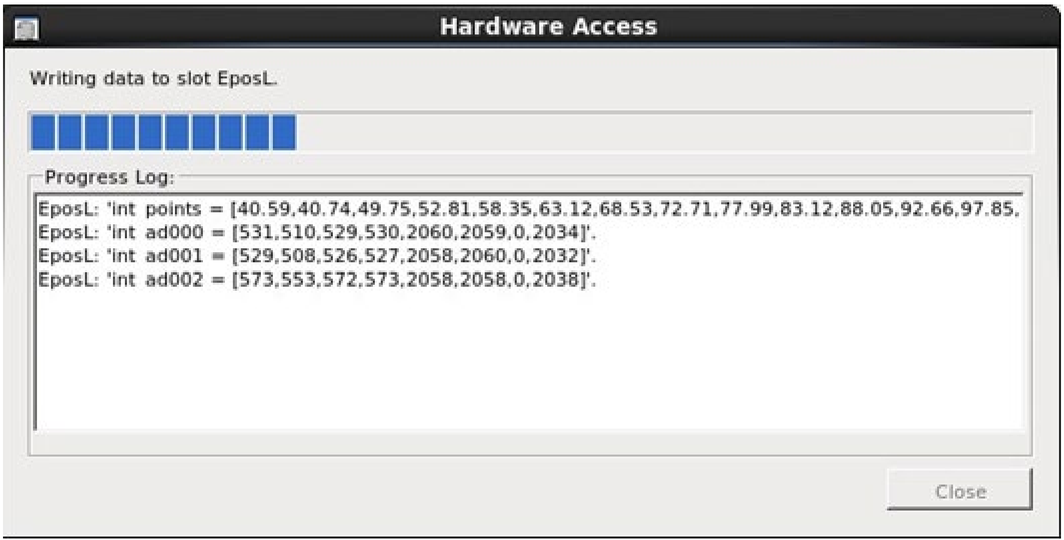

Figure 8 - Transferring the calibration data to an EPOS unit - start

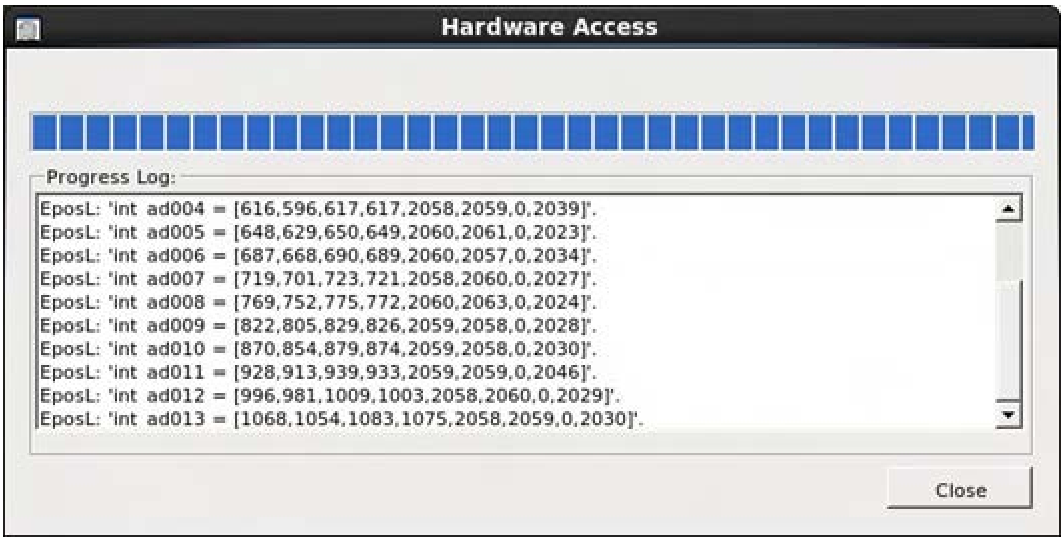

Figure 9 - Transferring the calibration data to an EPOS unit - end

5.4 Close the log window by clicking the <Close> button.

APPENDIX A - List fields "External Calibration Manager"

<table>
<tr><th>Designation / Column</th><th colspan="2">Description</th></tr>
<tr><td>Available points</td><td colspan="2"></td></tr>
<tr><td></td><td colspan="2">This list shows all the EPOS units (measuring systems) logged into and active on the EPOS system.
EPOS units with an error status are greyed.</td></tr>
<tr><td rowspan="5">Slot</td><td colspan="2">Designation of the measuring system; the following measuring systems are possible:</td></tr>

END

Includes:	EPOS - RSR123 Wheel Sensor (HABD)
Excludes:	All other uses of the RSR123 Wheel Sensor

1. Voltage adjustment RSR123

1.1 The voltage adjustment via software is performed using the application "Satellite Management UI" Application.

1.2 Open the "Satellite Management UI" application by double clicking the corresponding “satGUI” icon on the desktop of the FUES-EPOS system.

1.3 Open the "Calibration" menu and click "Wheel sensor calibration” and a second drop-down menu showing “RR", “MK” or “GR” appears, click as required. See Figure 1.

If several wheel sensors need adjusting, use "All" to adjust all wheel sensors at the same time.

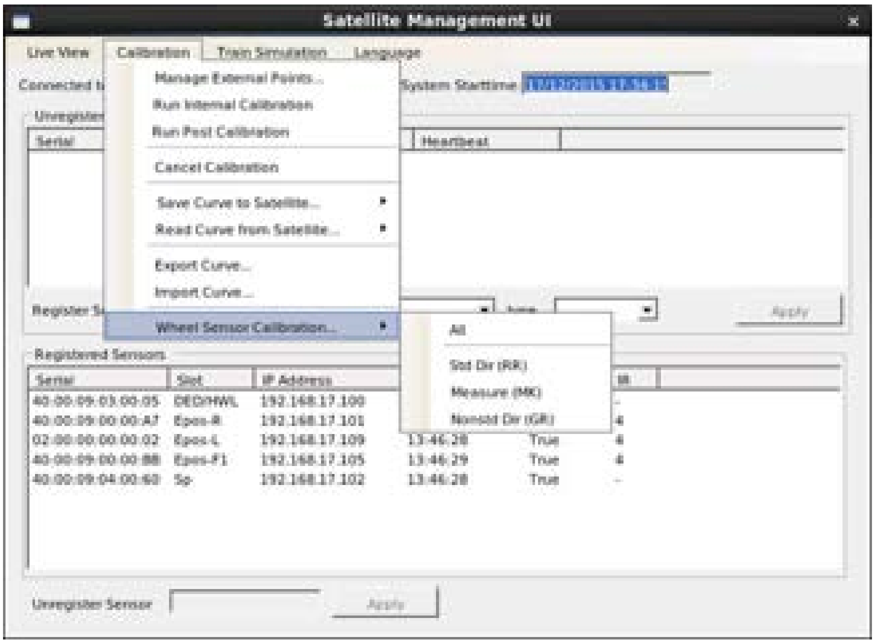

Figure 1 - Voltage adjustment of RSR123 – via software

1.4 Making a selection starts the process.

a) The status of the adjustment is displayed by a progress bar.

b) The completion of the adjustment is displayed by pop-up window.

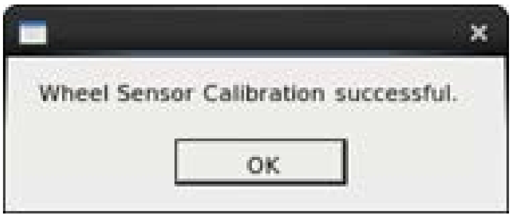

Figure 2 - Pop-up window after completion of the adjustment

END

SERVICE A TESTS

Details of the indications to be expected can be found in Appendix A

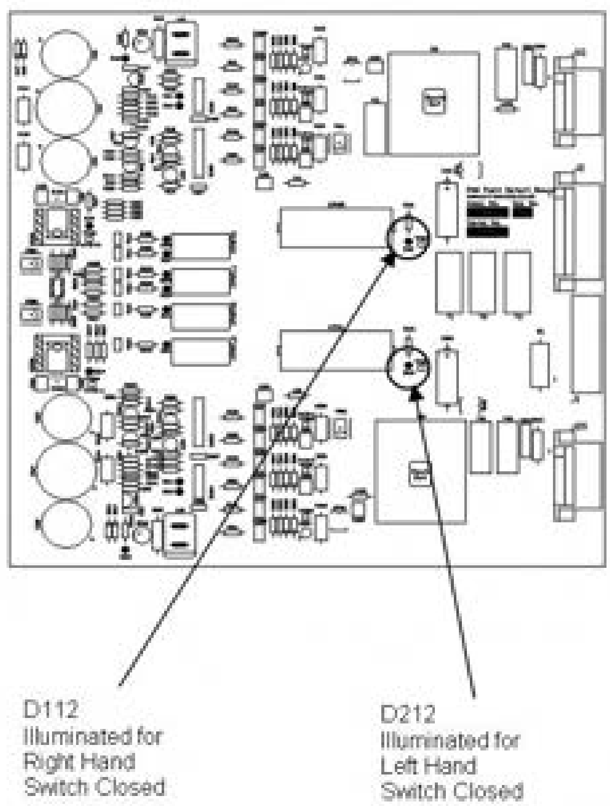
1. Test

1.1 Operate the points normal and reverse in turn and check that the Points Operating Module (POM) indications (Figure 1) and the Points Adaptor Module (PAM) detection relays (Figure 2) correspond with the lie of the points.

1.2 Check the position of the Signallers control device for the points and the Signallers indications correspond with the lie of the points.

APPENDIX A - Equipment Identification

Figure 1 - Point Operating Module (POM)



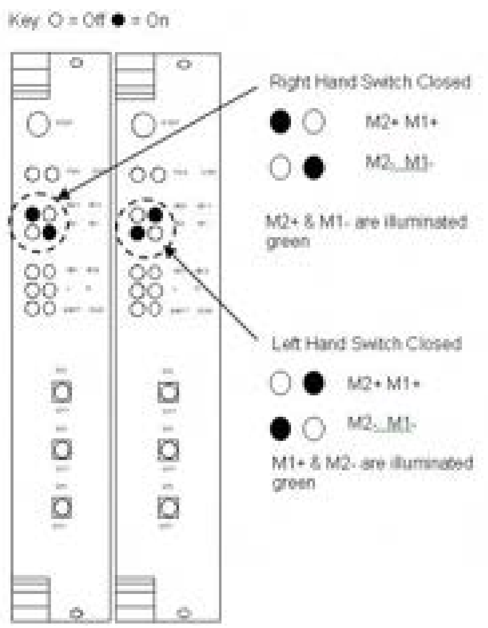


Figure 2 - Points Detect Module (PAM)

END

Details of the location of indications and push buttons can be found in Appendix A.

Abbreviations

LHSC: Left hand switch closed RHSC: Right hand switch closed

SERVICE B TESTS

1. Test

1.1 Check that the points operate correctly with no faults indicated or observed.

1.2 Move the points to the RHSC position. Check that D112 is illuminated and D212 extinguished.

1.3 Remove the lightning suppressors 4 & 5 to disconnect the PAM 4-wire interface.

1.4 Press PB21 and hold for approximately 1 second.

This will generate a simulated fault in the LHSC safety relay. D109/209 will illuminate and D111/211 will extinguish.

1.5 Perform a continuity check at the PAM side (top) of the terminal rail, to verify the following configuration (Figure 1):

a) Terminals 10, 12, & 15 connected together.

b) Terminal 13 not connected.

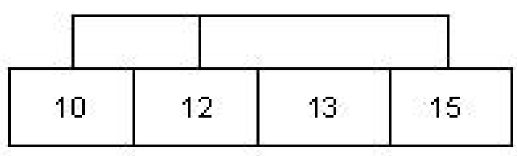

Figure 1 – Configuration 1

1.6 Remove and re-instate the auxiliary power to the Points Adaption Module (PAM) at terminals 54 &55. D109/209 will extinguish and D111/211 will illuminate, as for normal operation. The bi- stable fault relays shall both still be set.

1.7 Perform a continuity check at the PAM side (top) of the terminal rail, to verify the following configuration (Figure 2):

- Terminals 10, 12, 13 & 15 connected together.

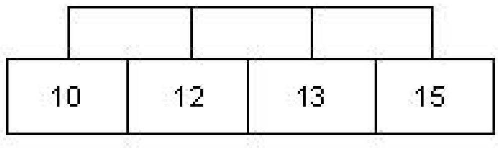

Figure 2 – Configuration 2

1.8 Press PB10. D110 should flash momentarily and the RHSC bi-stable fault relay should be reset.

1.9 Perform a continuity check at the PAM side (top) of the terminal rail, to verify the following configuration (Figure 3):

- Terminal 10,12,13,15 connected together

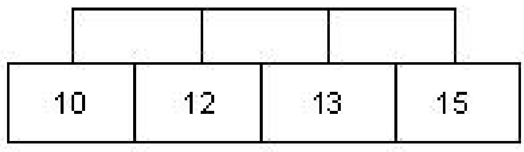

Figure 3 – Configuration 3

1.10 Press PB20. D210 should flash momentarily and the LHSC bi-stable fault relay should be reset.

1.11 Perform a continuity check at the PAM side (top) of the terminal rail, to verify the following configuration (Figure 4):

a) Terminal 10 connected to terminal 13

b) Terminal 12 connected to terminal 15

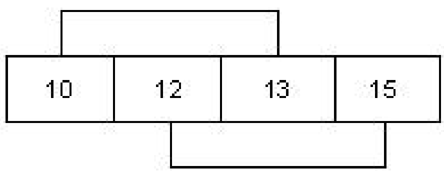

Figure 4 – Configuration 4

1.12 Replace lightning suppressors 4 & 5 to re-connect the PAM 4-wire interface.

1.13 Move the points to the LHSC position. D212 should be illuminated and D112 extinguished.

1.14 Remove lightning suppressors 4 & 5 to disconnect the PAM 4-wire interface.

1.15 Press PB 11 and hold for approximately 1 second.

This will generate a simulated fault in the RHSC safety relay. D109/209 will illuminate and D111/211 will extinguish.

1.16 Perform a continuity check at the PAM side (top) of the terminal rail, to verify the following configuration (Figure 5):

a) Terminal 10, 12, & 15 connected together.

b) Terminal 13 not connected.

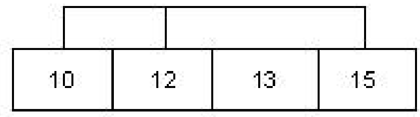

Figure 5 – Configuration 5

1.17 Remove and re instate the auxiliary power to the PAM at terminals 54 & 55. D109/209 will extinguish and D111/211 will illuminate, as for normal operation. However, the bi-stable fault relays shall still be set.

1.18 Perform a continuity check at the PAM side (top) of the terminal rail, to verify the following configuration (Figure 6):

- Terminals 10, 12, 13 & 15 connected together

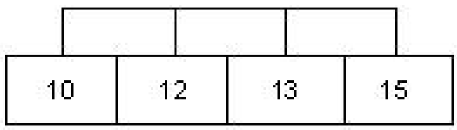

Figure 6 – Configuration 6

1.19 Press PB 20. D210 should flash momentarily and the LHSC bi-stable fault relay should be reset.

1.20 Perform a continuity check at the PAM side (top) of the terminal rail, to verify the following configuration (Figure 7):

- Terminals 10, 12, 13 & 15 connected together

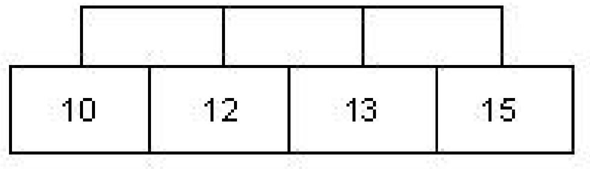

Figure 7 – Configuration 7

1.21 Press PB 10. D110 should flash momentarily and the RHSC bi-stable fault relay should be reset.

1.22 Perform a continuity check at the PAM side (top) of the terminal rail, to verify the following configuration (Figure 8):

a) Terminal 10 connected to terminal 12

b) Terminal 13 connected to terminal 15

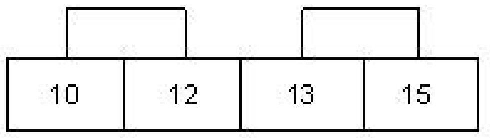

Figure 8 – Configuration 8

1.23 Replace lightning suppressors 4 & 5 to re- connect the PAM 4-wire interface.

NOTE: *It is important that all continuity testing is conducted at the top of the terminal rail. (i.e. the PAM side of the WAGO links).*

If the continuity testing is conducted on the wrong side of the WAGO links (incoming cable side), then the points detect module will not be tested correctly. This may also cause the POM to go in to error mode.

APPENDIX A - Point Detection Module

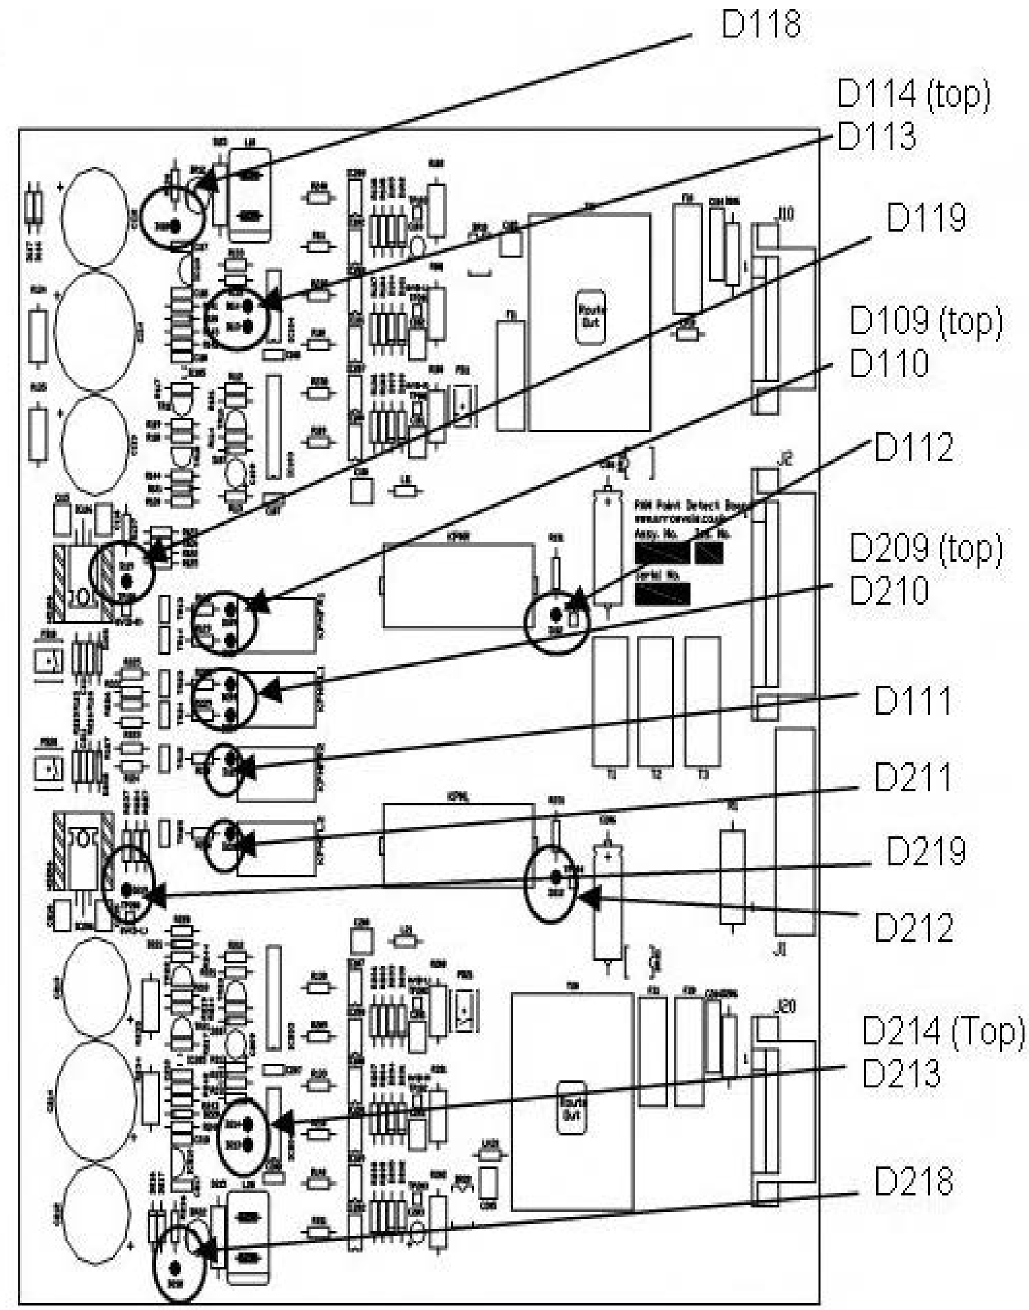

Figure 9 - The position of the LED indicators on the point detection module

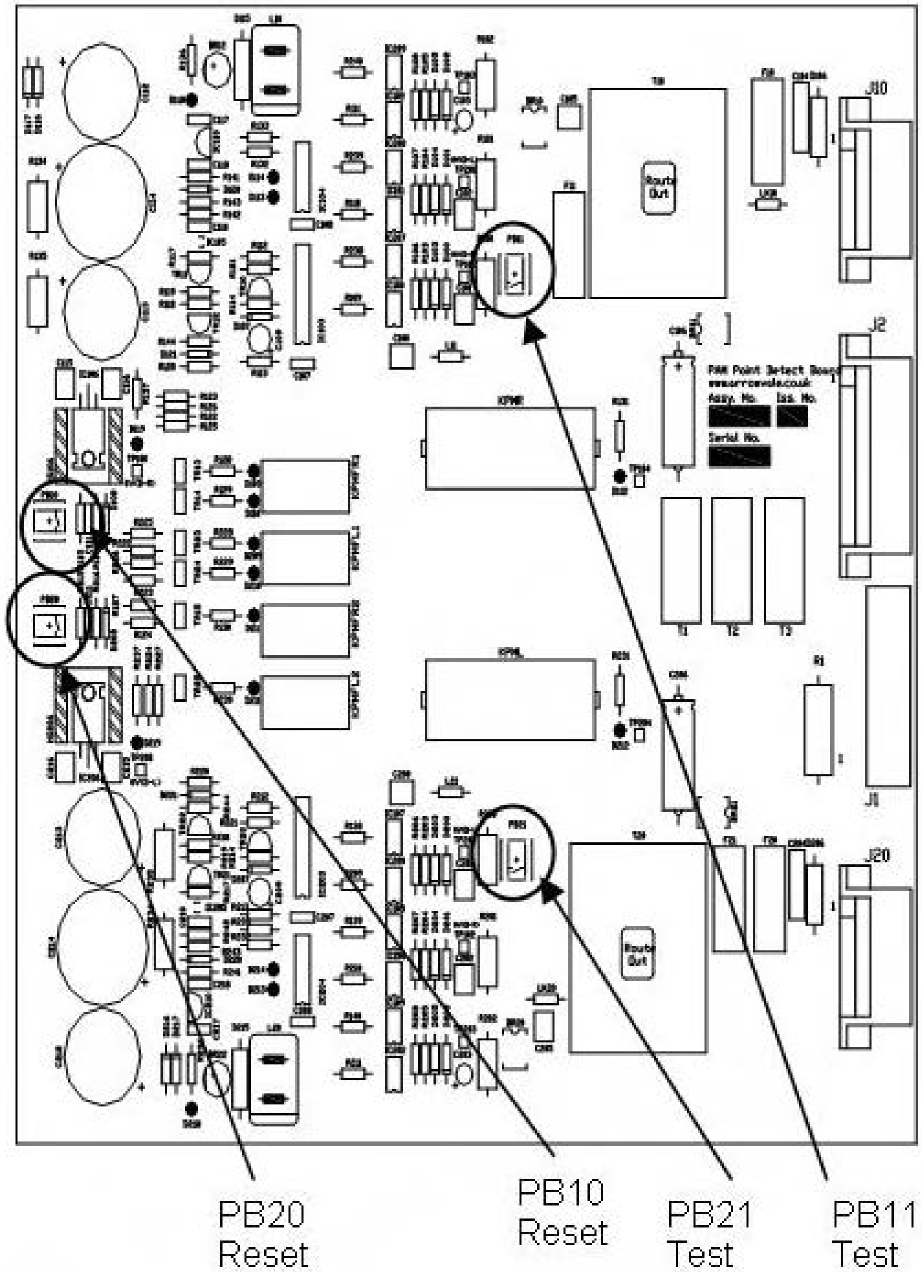

Figure 10 - The location of the push buttons on the point detector module

END

Details of the waveforms and connection of the dummy load resisters can be found in Appendix A.

Equipment Required Fluke 199 Scopemeter LEM PR 30 Current Probe.

1. Test

1.1 Connect the LEM current probe to Channel A of the Scopemeter and switch on both the Scopemeter and the probe.

1.2 Set up the equipment as follows:

a) Set channel A to be scaled in Amps.

b) Adjust the current probe offset to zero using the Scopemeter.

c) Set the Scopemeter to 500ms/div (with a 500ms pre-trigger) and a vertical scale of 1A/div.

d) Set the trigger to channel A (positive edge), 0.5A and single shot.

1.3 Connect the current probe to terminal 15 (connection L2 of the 4 wire interface).

1.4 Move the point machine in both directions and check that the envelope of the current waveform is always greater than 2.0A throughout the movement.

a) If this is the case (see Appendix A, Figure 1) then the dummy load resistors are not required.

b) If this is not the case (see Appendix A Figure 2) then the dummy resistors shall be connected in circuit.

1.5 If the dummy load resistors have been fitted, repeat 1.4 to check the current waveform is now correct.

1.6 Connect the current probe to terminal 12 (N connection of the 4 wire interface).

1.7 Move the points in both directions and check the envelope of the current waveform.

A distinct “blip” should be noticeable at the end of the waveform (see Appendix A Figure 3), this signifies that the point has reached its end position under power and the load resistors do not have to be fitted.

1.8 If this “blip” is not observed at the end of the waveform (see Appendix A, Figure 4 4), this would suggest that the points operating module has switched off power prematurely and the point machine is “freewheeling” into position.

This is not an acceptable condition and the dummy load resistors shall be connected in circuit.

1.9 If dummy load resistors have been fitted, repeat 1.7 to confirm the current waveform is now correct.

APPENDIX A - Scope Traces

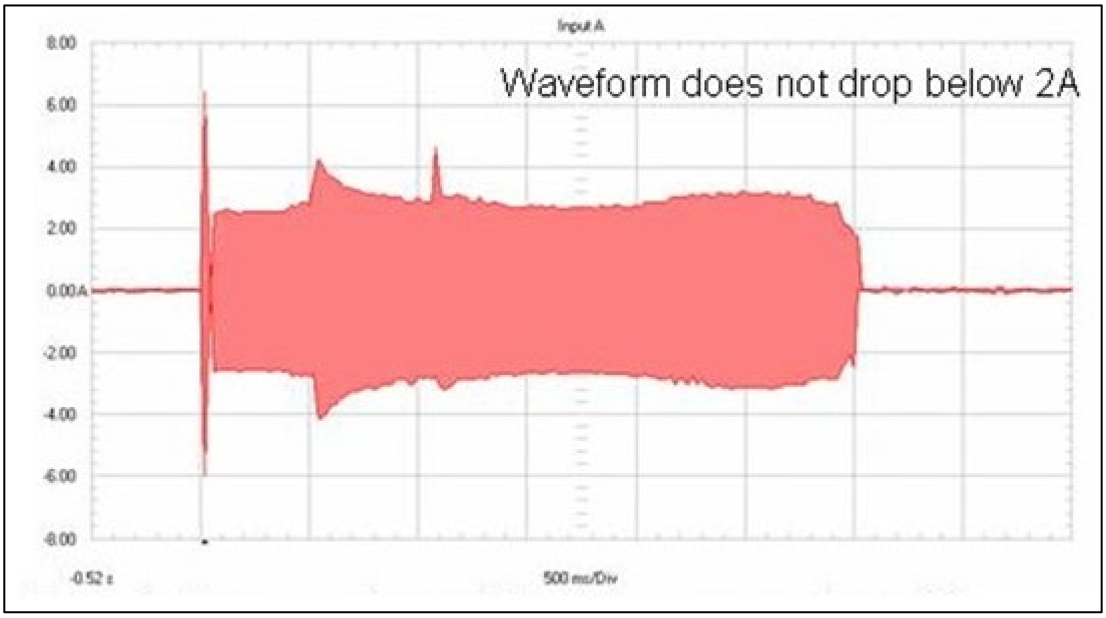

Figure 1 – Trace 1: Current probe on L2, running current above 2A
Dummy load resistors not necessary

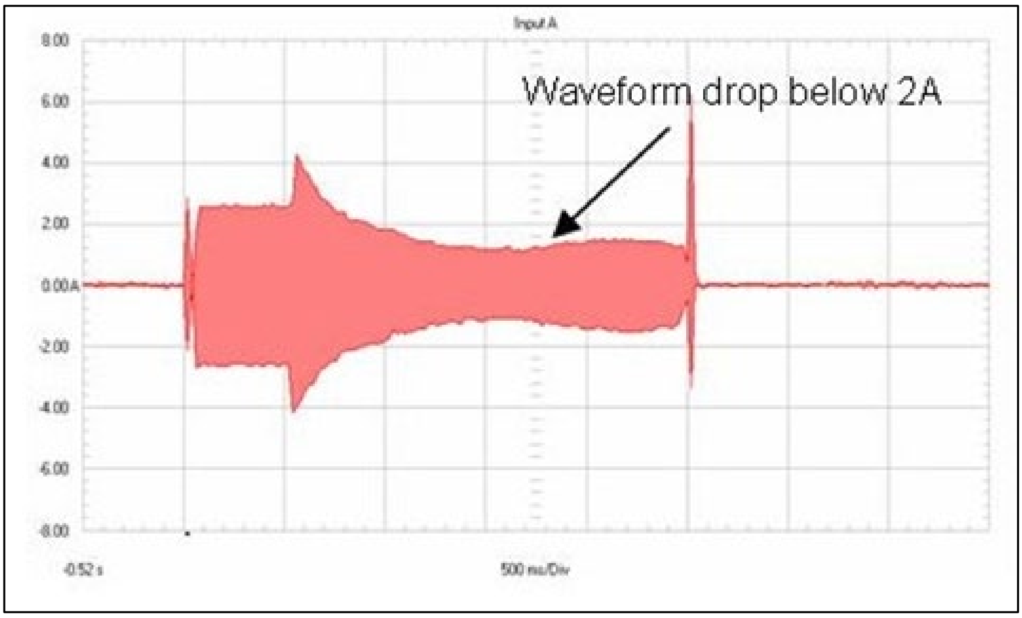

Figure 2 – Trace 2: Current probe L2, running current 2A
Dummy load resistors necessary

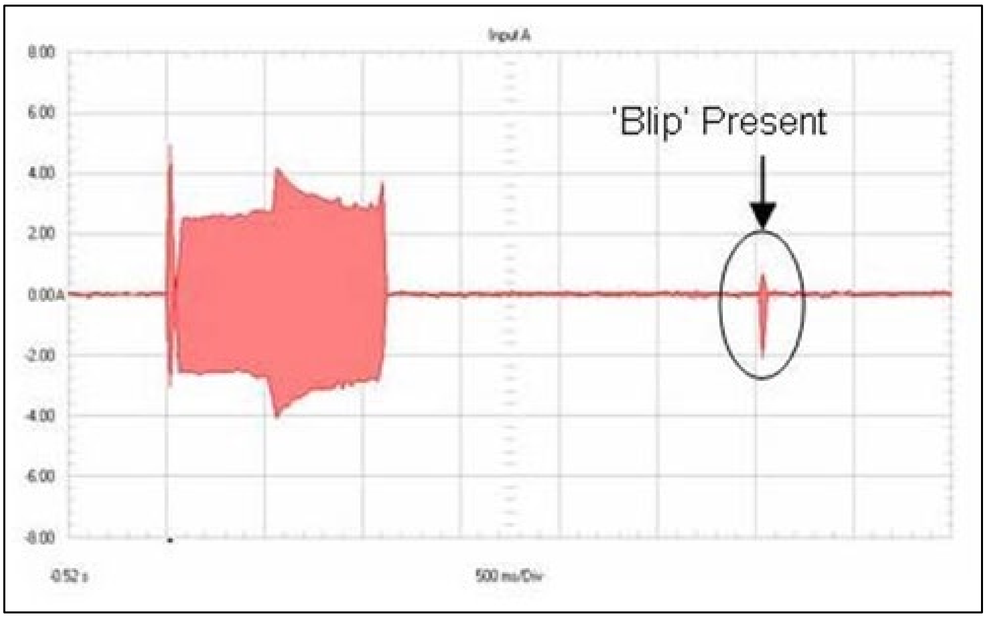

Figure 3 – Trace 3: Current probe on N, correct operation
Dummy load resistors not necessary

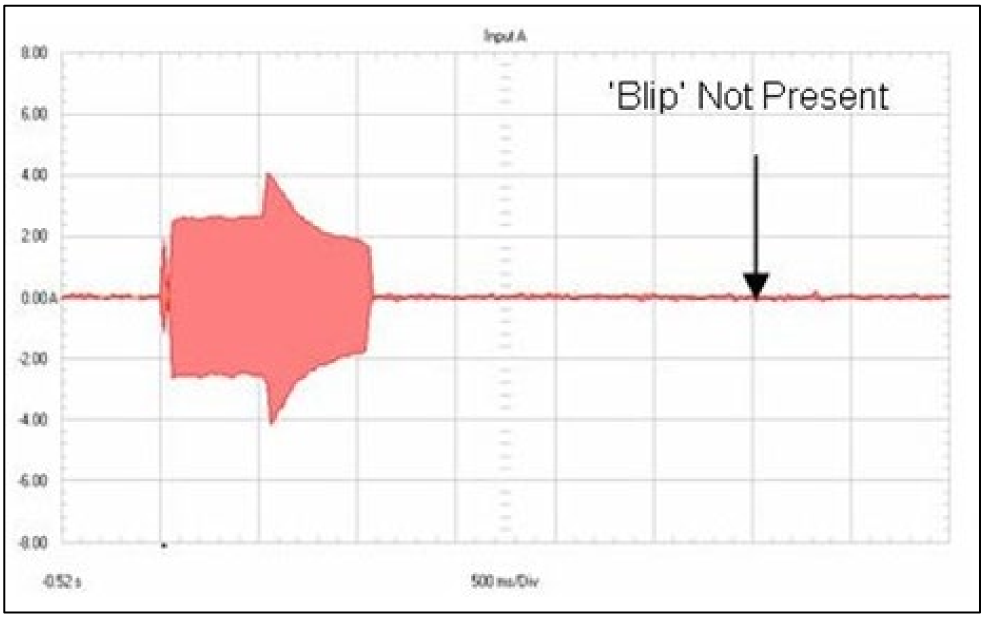

Figure 4 – Trace 4: Current probe N, Incorrect Operation
Dummy load resistors necessary

Connection of dummy load resistors.

1. Isolate the Points Adaption Module.
2. Remove the protective plastic cover protecting the motor power module.
3. Move the connection from J11 to J10, J13 to J12 and J15 to J14.
4. Replace the protective plastic cover protecting the motor power module.
5. Reconnect the Points Adaption Module.

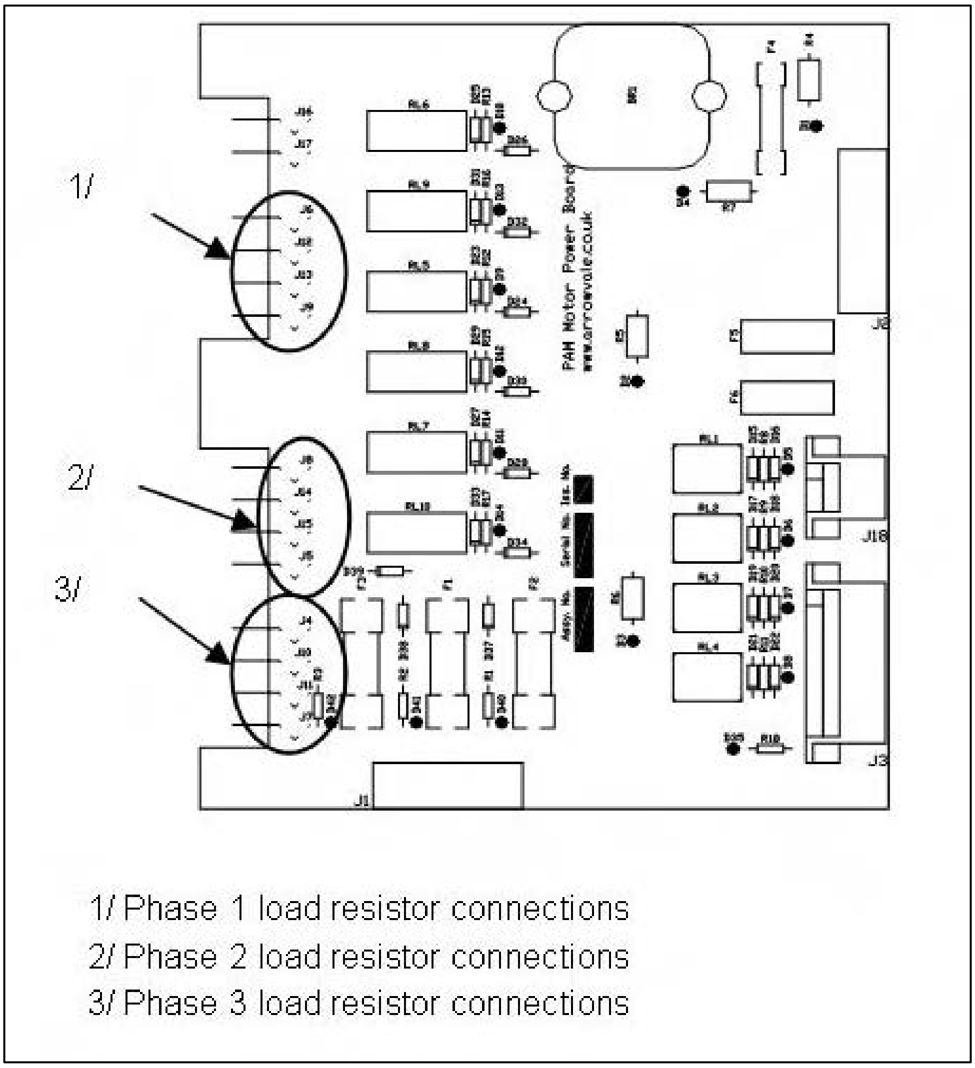

Figure 5 – Motor Power Module

END

Additional information on the KVB test set can be found in SMS Appendix 23

1 Balise Test

1.1 A balise test requires the test tool to be set flat on the balise along its longitudinal axis, after turning on the tester, the following message is displayed;

		A	P	P	U	Y	E	R		s	u	r		L	E	C	T		
			p	o	u	r		d	e	c	l	e	n	c	h	e	r		
							l	e		t	e	s	t						

1.2 Pressing the ‘LECT’ (read) key initiates the 27.115MHz signal towards the Balise to allow reception of a complete message.

Marker Balise

When the tester recognises a message from a Marker Balise, the display is as follows:

					M	A	R	Q	U	E	U	R							

Fixed or Switchable Balise

When the tester recognises a Fixed or Switchable Balise, with triplet data being transmitted, the display is as follows:

A	:	[	>	<	-	]													
X	:	5	M	E	9	4													
Y	:	C	M	2	1	D													
Z	:	7	M	4	0	1													

1.3 Observe the message being displayed on the KVB test set and confirm it is correct by comparing the DCO files and the signal aspect displayed.

1.4 To return to start, press ‘ECHAP’ (escape) Key.

2 “Presence train” Test, from the Balise

This test is intended to replicate the presence of a train. This is achieved by illuminating the yellow LED on the front face of the encoders UCS card when one of the balise’s driven by this encoder is energized by the test tool.

Due to the speed of the train, the energization time is too short for the LED to be seen lit by an observer.

2.1 A ‘presence train’ test requires the test tool to be set flat on the balise along its longitudinal axis, after turning on the tester, the following message is displayed;

```
  APPUYER sur LECT
   pour declencher
       le test
```

2.2 Press ‘1’ and the display will show the following message;

```
TEST PRESENCE TRAIN

maintenir LECT
    pendant le test
```

(Presence train test – Keep pressing LECT (read) during the test)

2.3 With one person at the balise, and one person at the encoder, Press and hold the ‘LECT’ (read) and check the yellow LED illuminates.

2.4 Return to main menu by releasing the ‘LECT’ (read) key and press ‘ECHAP’ (escape) Key.

3 Test of Encoder Output at Tail Cable

3.1 The tool must be connected to the end of the tail cable at the plug coupler of the balise, after turning on the tester, the following message is displayed:

```
  APPUYER sur LECT
   pour declencher
     le test
```

3.2 Press ‘LECT’ (read) to read the message coming from the encoder.

3.3 Compare message displayed to the DCO/Wiring Diagrams.

3.4 To return to start, press ‘ECHAP’ (escape) Key.

3.5 Repeat steps above for different aspects/messages if required.

4 Test from SBI Maintenance Card.

4.1 Connecting the tester to the SBI maintenance card, after turning on the tester, the following message is displayed:

	T	E	S	T		S	U	R		C	O	D	E	U	R		N		:
E	n	t	r	e	r		l	e		n	u	m	é	r	o		d	e	
l	a		s	o	r	t	i	e		a		t	e	s	t	e	r		
t	o	u	c	h	e	:		1	,		2	,		3		o	u		4

(Test on encoder N – Enter the output number to be tested – Key 1, 2, 3 or 4).

4.2 Choose the output that requires testing by pressing the relevant output key.

Pressing on any key ‘1’, ‘2’, ‘3’, or ‘4’ causes the tool to communicate towards the relevant output.

4.3 To return to start, press ‘ECHAP’ (escape) Key.

END

Includes:	Electromagnetic Lock when used at Level Crossing
Excludes:	All other Electromagnetic Lock Test

1. Indications Test

1.1 Check the crossing keeper/signallers crossing indication is illuminated when gate is closed and locked. Now check the following :

a) The alarm sounds within 3 seconds when gates are not locked.

b) The indication light does not illuminate when gate is closed and not locked.

c) The audible warning sounds and the fault light indications illuminate when gate is closed but not locked.

d) The audible warning can be cancelled by pressing the alarm acknowledge push button

e) Repeat 1.1 steps a) to d) for each crossing gate.

2. The Hall Effect Switch Test

2.1 Open the gate and place a single plastic blue .002mm disposable gauge between the lock and the armature (Figure 1) and carry out the following: -

Figure 1 - Magnetic lock mechanism

a) Energise the lock and observe that after approximately three seconds the audible warning sounds in the signal box and the fault light indications illuminates **do not** sound or illuminate.

b) Check that two people pushing each gate cannot force the gates open (Figure 2).

The gate should be pushed by applying pressure to the gate from a standing position, without jarring or shoving.

c) De-energise the lock and remove the gauge.

Figure 2 - Push Test

d) Repeat for all other gates.

2.2 After this test is complete recheck indications and audible alarms are functioning correctly for each gate before leaving site.

The plastic gauge shall only be used for one level crossing and disposed of. A new gauge shall be used for subsequent testing at other level crossings.

END

Includes:	Phoenix MD sensors only
Exclude:	All other types of HABD Sensor

The Variotherm works from a 230v supply.

The sensors shall have been in continuous operation for at least 1 hour before the test (2 hours if they have been switched off for more than half an hour).

Calibration Test

An on-site recalibration of the sensors can be undertaken to adjust any drift in measured values within reasonable limits.

Recalibration is only permitted in “Super” mode. The system / sensors are required to be stable before calibration is commenced.

Recalibration involves four steps:

1 Measured Values : Comparing measured values against a reference value

2 Determining the correction values

3 Transferring the correction values to the sensor.

4 Checking the results.

1 Measured Values

1.1 Select “Super” from the System Menu.

1.2 Select “DiMo” from the SCT Menu.

1.3 Maximise the DiMo window.

1.4 Enter the command “Testmode ON” to suppress data to the Signaller.

<u>**HDB1 Low Value**</u>

1.5 Enter the command “NKAL H1 ON” to suppress auto-calibration.

1.6 Enter the command “KASTFULL H1”

The SCT symbol will change from M to S whilst the standardisation is running, then to M again.

1.7 Enter the command “NACHKAL H1 ON” to commence calibration for the respective sensor under test.

1.8 Place the Heat Source on the sensor and check it is fitted correctly.

1.9 Set to the desired temperature of 60ºC.

1.10 Enter the command “MMS H1 ON” to commence reading the measured values of the sensor under test. Once the incoming values appear to be stable stop reading the measured values by entering the command “MMS H1 OFF”.

1.11 Measure and record the value in the calibration section of the paper or digital record card.

HDB1 High Value

1.12 Adjust to the desired temperature of 110ºC.

1.13 Enter the command “MMS H1 ON” to commence reading the measured values of the sensor under test. Once the incoming values appear to be stable stop reading the measured values by entering the command “MMS H1OFF”.

1.14 Measure and record the value in the calibration section of the paper or digital record card.

HDB2 Low Value

1.15 Allow the Heat Source time to cool below 60ºC.

1.16 Enter the command “NKAL H2 ON” to suppress auto-calibration.

1.17 Enter the command “KASTFULL H2”.

1.18 Enter the command “NACHKAL H2 ON” to commence calibration for the respective sensor under test.

1.19 Place the Heat Source on the sensor and check it is fitted correctly.

1.20 Adjust the Heat Source to 60ºC.

1.21 Enter the command “MMS H2 ON” to commence reading the measured values of the sensor under test. Once the incoming values appear to be stable stop reading the measured values by entering the command “MMS H2OFF”.

1.22 Measure and record the value in the calibration section of the paper or digital record card.

HDB2 High Value

1.23 Adjust the Heat Source to 110ºC.

1.24 Enter the command “MMS H2 ON” to commence reading the measured values of the sensor under test. Once the incoming values appear to be stable stop reading the measured values by entering the command “MMS H2 OFF”.

1.25 Measure and record the value in the calibration section of the paper or digital record card.

HWD1 Low Value

1.26 Enter the command "NKAL F1 ON" to suppress auto-calibration.

1.27 Enter the command "KASTFULL F1".

1.28 Enter the command "NACHKAL F1 ON" to commence calibration for the respective sensor under test.

1.29 Place the Heat Source on the rail sensor and check it is fitted correctly.

1.30 Adjust the Heat source to 200ºC.

1.31 Enter the command "MMS F1 ON" to commence reading the measured values of the sensor under test. Once the incoming values appear to be stable stop reading the measured values by entering the command "MMS F1 OFF".

1.32 Measure and record the value for channels 1 to 4 in the calibration section of the paper or digital record card.

1.33 Place the Heat Source on the centre sensor and check it is fitted correctly.

1.34 Enter the command "MMS F1 ON" to commence reading the measured values of the sensor under test. Once the incoming values appear to be stable stop reading the measured values by entering the command "MMS F1 OFF".

1.35 Measure and Record the value for channels 5 to 8 in the calibration section of the paper or digital record card

HWD1 High Value

1.36 Adjust the Heat source to 350ºC.

1.37 Enter the command "MMS F1 ON" to commence reading the measured values of the sensor under test. Once the incoming values appear to be stable stop reading the measured values by entering the command "MMS F1 OFF".

1.38 Measure and Record the value for channels 1 to 4 in the calibration section of the paper or digital record card.

1.39 Place the Heat Source on the centre sensor and check it is fitted correctly.

1.40 Enter the command "MMS F1 ON" to commence reading the measured values of the sensor under test. Once the incoming values appear to be stable stop reading the measured values by entering the command "MMS F1 OFF".

1.41 Measure and Record the value for channels 5 to 8 in the calibration section of the paper or digital record card.

<u>HWD2 Low Value</u>

1.42 Allow the Heat Source time to cool below 200ºC.

1.43 Enter the command “NKAL F2 ON” to suppress auto-calibration.

1.44 Enter the command “KASTFULL F2”.

1.45 Enter the command “NACHKAL F2 ON” to commence calibration for the respective sensor under test.

1.46 Place the Heat Source on the rail sensor and check it is fitted correctly.

1.47 Adjust the Heat source to 200ºC.

1.48 Enter the command “MMS F2 ON” to commence reading the measured values of the sensor under test. Once the incoming values appear to be stable stop reading the measured values by entering the command “MMS F2 OFF”.

1.49 Measure and record the value for channels 1 to 4 in the calibration section of the paper or digital record card.

1.50 Place the Heat Source on the centre sensor and check it is fitted correctly.

1.51 Enter the command “MMS F2 ON” to commence reading the measured values of the sensor under test. Once the incoming values appear to be stable stop reading the measured values by entering the command “MMS F2 OFF”.

1.52 Measure and Record the value for channels 5 to 8 in the calibration section of the paper or digital record card.

2 Determining Correction Values

2.1 Double-click on the “Nachkal” icon on the Windows user interface. A screen titled “Phoenix MB Nachkalibrierung” will be displayed.

2.2 Select the sensor that you wish to enter values for by clicking on the respective target.

2.3 Enter the temperature values that you have noted down for each respective channel against the correct measured temperature.

2.4 After entering the values for both temperature settings click the “Calculate” button. The values for offset and gain for each channel will be calculated and displayed.

2.5 Click “OK” and the measured values are tested against offset and gain limits. These limits are listed as follows:

- HBD Limits = [-15< Offset < 15], [0.8 < Gain < 1.2]
- HWDSB = [-30< Offset < 30], [0.8 < Gain < 1.2]

2.6 If the measured values pass this test the correction values is written to the hard disk. Follow the on screen commands to terminate the program.

3 Transferring Correction Values to Sensor

Enter the command "NACHKAL H1 OFF" in the DiMo window.

This transfers the values stored on the hard disk drive to the appropriate sensor.

At this stage the process ends for one sensor and needs to be repeated for each of the other sensors.

4 Checking the Results

In the following sections If an "x" is shown in a command it should be substituted for the following alphanumeric code associated with the sensor being worked on:

a) For HBD1 = H1
b) For HBD2 = H2
c) For HWD1 = F1
d) For HWD2 = F2

4.1 Enter the command "PRE x" in the DiMo window.

This reads the sensor date from the flash memory.

4.2 Then enter the command "DPA x". This displays the most recent data read from the sensor.

4.3 The lines beginning with Gain and Offset display the correction values for each of the 8 channels.

4.4 The offset is a number divided by 100 whilst the gain is indicated by a number divided by 1000 (e.g. an Offset 123 equals 1.23 whilst a Gain 985 corresponds to 0.985).

4.5 Record the results on the appropriate paper or digital record card.

5 System Closure

5.1 Enter the command "Testmode OFF" in the DiMo window.

5.2 Enter the command "NKAL x OFF" to enable auto-calibration.

5.3 Enter the command "E" in the DiMo window to close the DiMo application.

End

NR/L3/SIG/10663 Signal Maintenance Specifications		
NR/SMS/Part E/Test /212		
Phoenix MD Accuracy Test		
Issue No. 1	Issue Date: 03/03/18	Compliance Date: 31/05/18

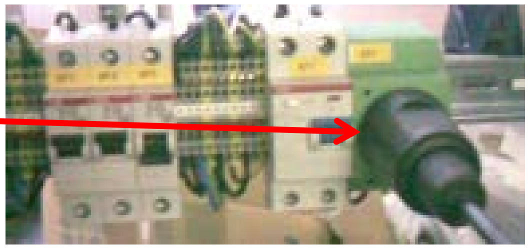
Includes:	Phoenix MD sensors only
Exclude:	All other types of HABD Sensor

The Variotherm works from a 230v supply.

The sensors shall have been in continuous operation for at least 1 hour before the test (2 hours if they have been switched off for more than half an hour).

1 Accuracy Test

1.1 Connect the Variotherm power supply to the socket in the SCT.



1.2 Check the mirrors are clean before the accuracy test is started.

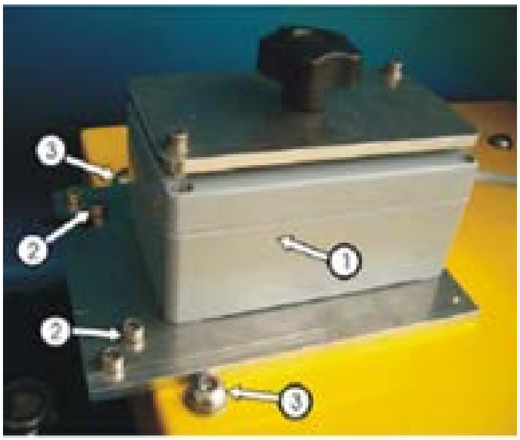
1.3 Switch the SCT to “test mode” to switch off error message reporting during the test.

Do not close the DiMo window.

1.4 Position a Variotherm heat source (1) on top of sensor HBD1.

1.5 The screws (2) shall be touching the sensor hood.

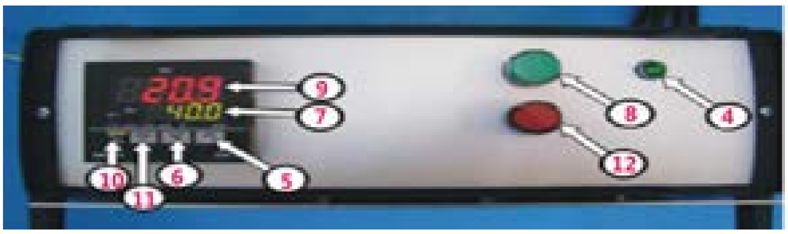
1.6 The Variotherm heat source (1) shall be positioned between the sensor hood screws (3).



1.7 Check the Variotherm Unit’s green power LED is Illuminated (4).

1.8 Using the up and down keys (5 & 6), set the target temperature to 70ºC (7).

1.9 Press green button (7) to activate the heater.



Actual temperature is shown (9).

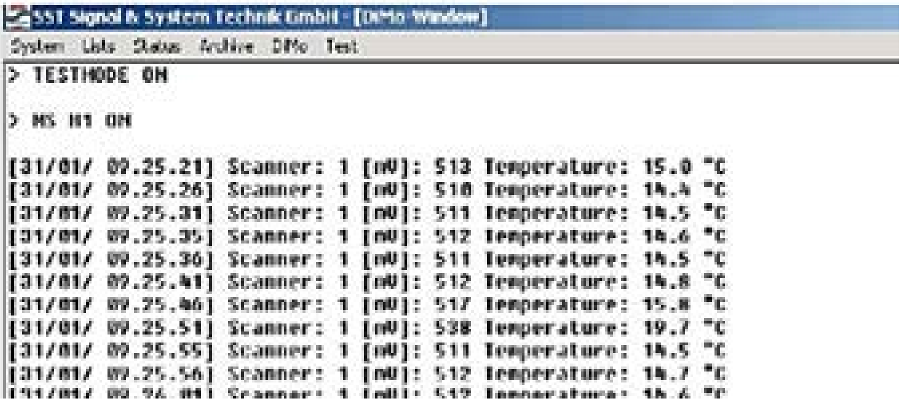
Do not press buttons 10 or 11, as they can affect the calibration.

The red button (12) switches the heater off

1.10 When the temperature shown by the Variotherm panel reaches 70ºC, move to the DiMo window and enter the command "MS H1 ON" and press enter.

H1 Addresses HBD1.

1.11 The HABD will report a temperature measurement every few seconds, and these measurements will be displayed in the DiMo window (Shown below).



1.12 When the readings have settled, stop the measuring process by entering the command "MS H1 OFF".

1.13 Measure and record the temperature on the appropriate paper or digital record card.

If the temperature falls outside the nominal value of 70ºC +/- 3ºC then you shall stop this test and carry out a full Calibration Test as shown in NR/SMS/Test 211.

1.14 Power down the Variotherm heat source using the red button before moving to the correct position on the top of the HBD2 sensor.

1.15 Press green button to activate the heater.

1.16 Using the up and down keys, check the target temperature is still set to 70ºC.

1.17 When the temperature shown by the Variotherm panel reaches 70ºC, move to the DiMo window and enter the command "MS H2 ON" and press enter.

H2 Addresses HBD2.

1.18 When the readings have settled, stop the measuring process by entering the command "MS H2 OFF".

1.19 Measure and record the temperature on the appropriate paper or digital record card.

1.20 If the temperature falls outside the nominal value of 70ºC +/- 3ºC then you shall stop this test and carry out a full Calibration Test as shown in NR/SMS/Test 211.

1.21 Leaving the Variotherm Heat source on HBD2 Use the up and down keys, move the target temperature to 120ºC.

1.22 When the temperature shown by the Variotherm panel reaches 120ºC, move to the DiMo window and enter the command “MS H2 ON” and press enter.

1.23 The HABD will report a temperature measurement every few seconds, and these measurements will be displayed in the DiMo window.

1.24 When the readings have settled, stop the measuring process by entering the command “MS H2 OFF”.

1.25 Measure and record the temperature on the appropriate paper or digital record card.

1.26 If the temperature falls outside the nominal value of 120ºC +/- 5ºC then you shall stop this test and carry out a full Calibration Test as shown in NR/SMS/Test 211.

1.27 Power down the Variotherm heat source using the red button before moving to the correct position on the top of the HBD1 sensor.

1.28 Press green button to activate the heater.

1.29 Using the up and down keys, check the target temperature is still set to 120ºC.

1.30 When the temperature shown by the Variotherm panel reaches 120ºC, move to the DiMo window and enter the command “MS H1 ON” and press enter.

1.31 When the readings have settled, stop the measuring process by entering the command “MS H1 OFF”.

1.32 Measure and record the temperature on the appropriate paper or digital record card.

1.33 If the temperature falls outside the nominal value of 120ºC +/- 5ºC then you shall stop this test and carry out a full Calibration Test as shown in NR/SMS/Test 211.

1.34 Power down the Variotherm heat source using the red button before moving to the correct position on the top of the HWD1 sensor.

1.35 Press green button to activate the heater.

1.36 Using the up and down keys, set the target temperature to 300ºC.

1.37 When the temperature shown by the Variotherm panel reaches 300ºC, move to the DiMo window and enter the command “MMS F1 ON” and press enter.

1.38 When the readings have settled, stop the measuring process by entering the command “MMS F1 OFF”.

1.39 Measure and record the temperature on the appropriate paper or digital record card.

1.40 If the temperature falls outside the nominal value of 300ºC +/- 10ºC then you shall stop this test and carry out a full Calibration Test as shown in NR/SMS/Test 211.

1.41 Power down the Variotherm heat source using the red button before moving to the correct position on the top of the HWD1 sensor.

1.42 Press green button to activate the heater.

1.43 Using the up and down keys, check the target temperature is still set to 400ºC.

1.44 When the temperature shown by the Variotherm panel reaches 400ºC, move to the DiMo window and enter the command “MMS F2 ON” and press enter.

1.45 When the readings have settled, stop the measuring process by entering the command “MMS F2 OFF”.

1.46 Measure and record the temperature on the appropriate paper or digital record card.

1.47 If the temperature falls outside the nominal value of 400ºC +/- 5ºC then you shall stop this test and carry out a full Calibration Test as shown in NR/SMS/Test 211.

1.48 If all temperature values fall within their respective nominal values there is no need to carry out a full Calibration Test.

End

Includes:	TPWS Modules or Transmitters
Excludes:	TPWS Self Powered OSS Module (SPOSS)

GENERAL

All tests requiring TPWS Transmitter Loop field strength and frequency measurements shall use a test meter approved for use with TPWS equipment.

The multimeter shall be set to the correct range to accurately measure frequency with a minimum resolution of 1 Hz.

All test measurements shall be recorded on the TPWS Test record card.

When the power supply to TPWS is disconnected, a fault report will be indicated every time the signal displays a red aspect.

When using the test equipment in third/fourth rail electrified areas, avoid contact between the test aerial lead and the conductor rails.

An 'affected loop' is one that is fed by a Module which has been disturbed/replaced, in which case the pair of loops associated with the Module shall be tested.

An 'affected Module' includes any disturbed/replaced by the work and any associated Signalling Interface Module (and the Overspeed Sensor / Train Stop Modules fed by a disturbed/replaced Signalling Interface Module).

VCR:

Some TPWS installations in SSI areas do not have a VCR relay. Instead, the proving output from the SIM goes directly into an input on a TFM.

To establish if a TPWS failure exists for these installations check either the SSI Technicians' terminal or the failure indication on the Signaller's panel. Indications are shown either as a red lamp failure of the fitted signal or as a TPWS failure.

Where a TPWS Failure Indication Unit (F.I.U.) is provided, a check of the failure indication is a key part of the maintenance requirements for the F.I.U.

The tests are applicable at all TPWS installations.

Tests

1. Initial Fault Reporting Status

1.1 Check that the VCR relay is energised.

1.2 Check that no fault indication is received at the signal-box.

2. Tests at the TSS and OSS Modules and Loops

2.1 Technicians shall be positioned at the correct loop and at the other TPWS enclosure.

Main Signal On (Red Aspect) Subsidiary Signal On (Not Illuminated)

2.2 Arrange for the signal to display a stop aspect (red) and for any suppression function to be de-energised (i.e. no subsidiary signal input or points controls).

2.3 Check that the VCR relay is energised.

2.4 Check that the following LEDs are lit:

Module	Function	LED
TSM/OSM	Main I/P	Yellow
SIM	Loops Active	Yellow

2.5 Check that no other LEDs change state.

2.6 Measure and record the voltage and frequency at the arming loop and the trigger loop (TSS, OSS).

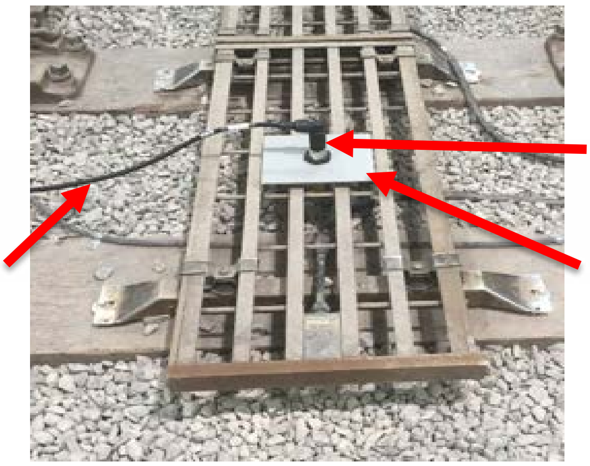


Figure 1: Measuring TPWS Field Strength - Maintenance Test

To measure the voltage and frequency, the TPWS test aerial shall be positioned centrally on the loop using the Maintenance Jig. The meter shall not be held over the loops, to avoid interference from the loop field. as shown in Figure 1.

Details of voltages and frequencies see NR/SMS/PartZ/Z08 (Train Protection - Reference Values).

2.7 The frequency shall within +/-0.01kHz of the stated frequency for each Transmitter Loop's function (f1 to f6 as specified on the location wiring diagrams).

3. Location and Signal-Box Indications

Main Signal On (Red Aspect) Subsidiary Signal On (Not Illuminated)

3.1 Measure the voltage on the outgoing links of each loop and check that:

a) The voltages are within +/- 20% from the first reading on the record card.

b) The difference between the TSS arming loop voltage and TSS trigger loop voltage is less than 0.3V AC.

c) The OSS arming loop voltage is greater than the OSS trigger loop voltage.

If any of the readings are out of tolerance this can indicate high resistance in the loop circuit.

To carry out the following tests, a Technician shall be positioned at the TPWS enclosure. Co-operation with the Signaller is required.

3.2 De-energise the OSS arming loop by slipping links to the loop output circuit and check that the following LED indications are shown:

Module	**Function**	**LED**
OSM/TSM	Fault	Red
SIM	Loop Active	Extinguished

3.3 Check that the VCR relay has de-energised.

3.4 Check that a fault indication is given to the Signaller.

3.5 Re-energise the OSS arming loop by remaking the links to the loop output circuit and check that the following LEDs are illuminated:

Module	**Function**	**LED**
OSM/TSM	Fault	Red
SIM	Loop Active	Yellow

3.6 Check that the VCR relay has energised.

3.7 Reset the system, check that the fault LED is extinguished.

3.8 Repeat tests 3.2 to 3.7 except step 3.4 for the OSS trigger loop.

3.9 Repeat tests 3.2 to 3.7 except step 3.3 for the TSS arming and trigger loops.

Main Signal On (Red Aspect) Subsidiary Signal Off (Illuminated) (If Applicable)

3.10 Arrange for the signal to display a stop aspect (red) and for any suppression function to be energised (i.e. subsidiary signal input).

3.11 Check that the following LEDs are lit:

Module	Function	LED
TSM	Main I/P	Yellow
TSM	Suppression Input	Yellow
TSM SIM	Loops Active	Extinguished

3.12 Check the LED indications on the OSS Modules:

Module	Function	LED
TSM	Main I/P	Yellow
TSM SIM	Loops Active	Yellow

4. Tests for PSR & Buffer Stops Only

For remote PSRs operated by the battery-powered OSS unit go to section 5.

4.1 Check that the green 'Power On' LEDs are illuminated on all modules for the PSR or buffer stop.

4.2 Check that the following LEDs are illuminated:

LED	Function	Colour
OSM	Mains I/P	Yellow
SIM	Loop Active	Yellow

4.3 Check that no other LEDs are illuminated (including fault LEDs).

Some PSR installations will have a suppression input with points controls and hence the yellow "Supp I/P" LED can be illuminated.

4.4 Measure and Record the voltage and frequency at the OSS arming loop and the OSS trigger loop.

a) The signal strength from each loop shall be no less than 29mV and no greater than 53mV measured with the meter set to the 50mV AC range.

b) The frequency shall be correct for the system (f1-f6) and within the tolerances listed in NR/SMS/PartZ/Z08 (Train Protection – Reference Values).

4.5 De-energise the OSS arming loop by slipping links to the loop output circuit and check that the following LED indications are shown:

LED	Function	State
OSM	Fault	Red
SIM	Loop Active	Extinguished

4.6 Check that the VCR relay has de-energised, (buffer stops only).

4.7 Re-energise the OSS arming loop by remaking the links to the loop output circuit and check that the following LED indications are shown:

LED	Function	State
OSM	Fault	Red
SIM	Loop Active	Yellow

4.8 Check that the VCR relay has energised.

4.9 Reset the system and check that the fault LED is extinguished.

4.10 Repeat tests 4.5 to 4.9 for the OSS trigger loop.

5. Final Checks

5.1 Check that the VCR relay is energised (buffer stops only).

5.2 Check that all green ‘Power’ LEDs are illuminated and that all ‘Fault’ LED’s are extinguished.

END

Includes:	TPWS Module or Transmitter
Excludes:	TPWS Self Powered OSS Module

This test is to check that the TPWS system is functioning correctly following plug-in Module replacement or a Transmitter Loop change following a failure

The test sequence checks the system logic and loop power of affected units in the plane of the loop.

An 'affected loop' is one that is fed by a Module which has been disturbed/replaced, in which case the pair of loops associated with the Module must be tested.

An 'affected Module' includes any disturbed/replaced by the work and any associated Signalling Interface Module (and the Overspeed Sensor / Train Stop Modules fed by a disturbed/replaced Signalling Interface Module).

All tests requiring TPWS Transmitter Loop field strength and frequency measurements shall use a test meter approved for use with TPWS equipment.

The multimeter shall be set to a range to accurately measure frequency with a minimum resolution of 1 Hz.

All test measurements shall be recorded on the record card.

1. Test - Following Equipment Failure

Prior to use, the TPWS Maintenance Jig and Test Aerial shall be visually inspected for damage.

1.1 Check the affected TPWS Module LEDs, by observing that only the green ‘power on’ LEDs are lit when the main signal is ‘off’ and any associated position light / semaphore subsidiary signal is unlit / on.

1.2 With the main signal ‘on’ check that the ’Main I/P’ LEDs are alight on the affected Train Stop and Overspeed Sensor Modules.

1.3 Use the TPWS test aerial to test the voltage received by the aerial and the frequency of the signal received at each affected Transmitter Loop in turn.

To measure the voltage and frequency, the TPWS test aerial shall be positioned centrally on the loop using the Maintenance Jig. The meter shall not be held over the loops, to avoid interference from the loop field. as shown in Figure 1.

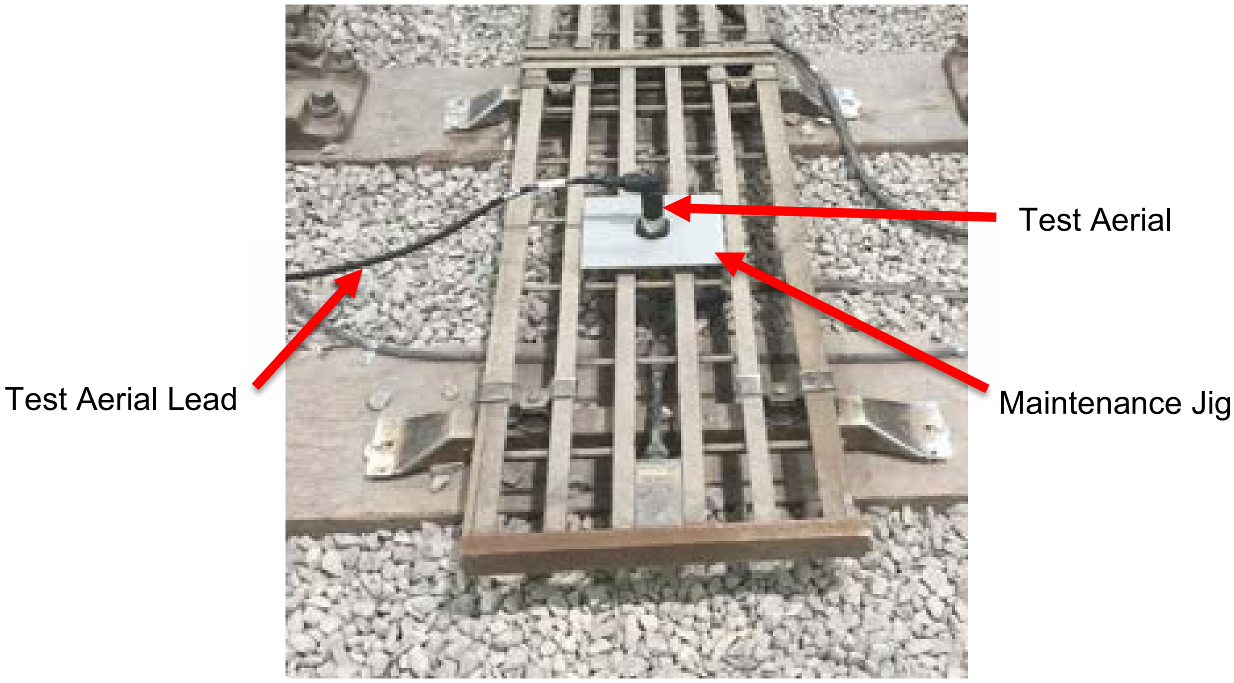

Figure 1: Measuring TPWS Field Strength - Maintenance Test

Details of voltages and frequencies see NR/SMS/PartZ/Z08 (Train Protection - Reference Values).

1.4 The frequency shall within +/-0.01kHz of the stated frequency for each Transmitter Loop's function (f1 to f6 as specified on the location wiring diagrams).

1.5 If a main signal has an associated position light / semaphore subsidiary signal arrange for it to be cleared to the 'off' position and check the 'Supp I/P' LED is illuminated on the affected Module and that no other LEDs change state.

Use the TPWS test aerial to test that the voltage received by the aerial at each affected Transmitter Loop is less than 2mV AC (at the TPWS tone frequency).

1.6 This test is only applicable where position light / semaphore subsidiary signal suppression is fitted)

With the main signal 'off' check that the 'Main I/P' and 'Supp I/P' LEDs are extinguished on the affected Train Stop and Overspeed Sensor Modules and that no other LEDs change state.

Use the TPWS calibrated test aerial to test that the voltage received by the aerial at each of the affected Transmitter Loops is less than 2mV AC (at the TPWS tone frequency).

1.7 If the Module or Transmitter Loop forms part of a Self-Powered OSS (SPOSS) then carry out NR/SMS/PartB/Test/233 - TPWS Self-Powered OSS (SPOSS) Trackside Equipment Test.

1.8 With the signal 'on', simulate a trackside equipment fault by slipping the links for the loop in the trackside apparatus case (OSS or TSS).

a) Check for correct fault indications on the affected module and in the Signal Box.

b) Remove the simulated fault.

c) Reset affected TPWS Modules.

This is done by undertaking a short (five second) isolation (disconnection of the BX110 supply fuse/link to the TPWS on the Baseplate or Trackside Enclosure).

1.9 Check that isolation fuses/links are in the correct position and that screw terminals are tight.

END

Includes:	TPWS Module or Transmitter Loop (following Pway Work)
Excludes:	Any TPWS Module or Transmitter Loop following a Failure

This test is to check that the TPWS system is functioning correctly following transmitter loop replacement associated with permanent way renewals work when the track bed has been laid.

The test sequence checks the transmitted power of the affected loops at 310mm above rail level.

An “affected loop” is one which has been disturbed or replaced by the “work”.

If the loops are to be disturbed as part of permanent way renewals work, then prior to any work commencing, the exact position of the loop shall be clearly marked.

If, because of the scope of the works, it was not possible to mark the original position of the loops prior to the works commencing, then re-measure the required distance (as shown on the location wiring diagram) from the associated signal to each loop.

This is likely to require re-measurement of the required distance (as shown on the location wiring diagram) from the associated signal.

All tests requiring TPWS Transmitter Loop field strength and frequency measurements shall use a test meter approved for use with TPWS equipment.

All test measurements shall be recorded on the TPWS Test record card.

1. Test - Following Equipment Removal and Refitting

Prior to use, the TPWS Commissioning Jig and Test Aerial shall be visually inspected for damage and to check correct alignment of the two mating halves.

1.1 Check that all loops are re-installed in the correct position.

1.2 Check the affected TPWS Module LEDs, by observing that only the green ‘power on’ LEDs are lit when the main signal is ‘off’ and any associated position light / semaphore subsidiary signal is unlit / on.

1.3 With the main signal ‘on’ check that the ’Main I/P’ LEDs are alight on the affected Train Stop and Overspeed Sensor Modules.

1.4 Use the TPWS test aerial to test the voltage received by the aerial and the frequency of the signal received at each affected Transmitter Loop in turn.

To measure the voltage and frequency, the TPWS test aerial shall be positioned centrally on the loop using the Commissioning & Maintenance Jigs.

The TPWS aerial should be placed into the top of the commissioning jig tube.

The meter shall not be held over the loops, to avoid interference from the loop field. as shown in Figure 1.

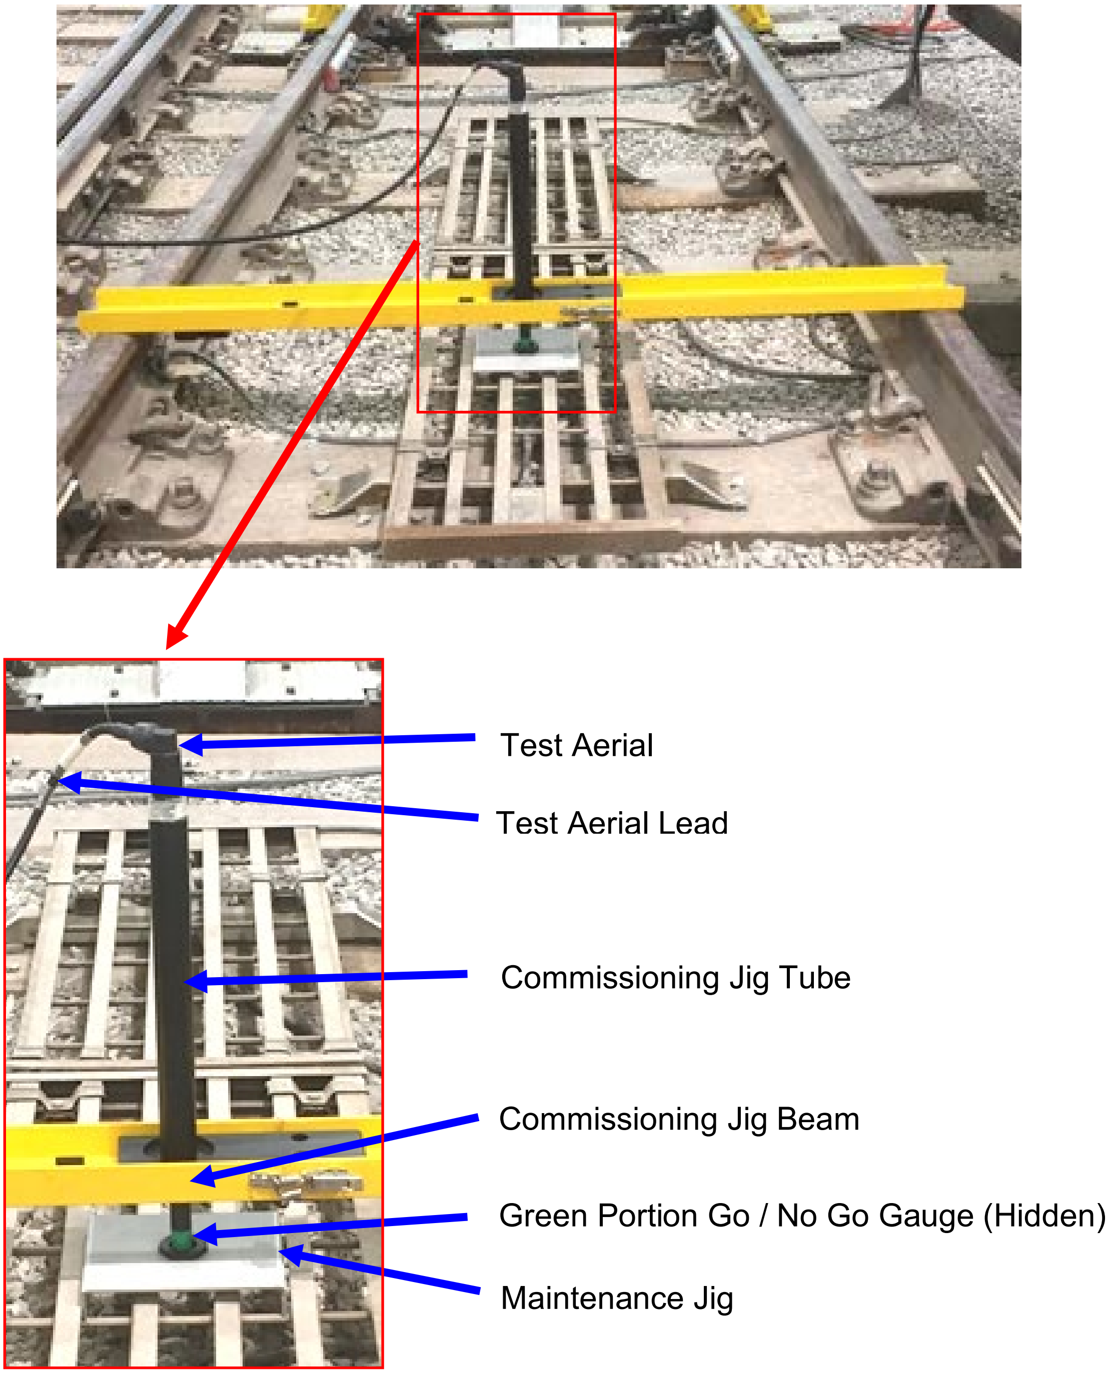

Figure 1: Measuring TPWS Field Strength - Commissioning Test

Details of voltages and frequencies see NR/SMS/PartZ/Z08 (Train Protection - Reference Values).

1.5 The frequency shall within +/-0.01kHz of the stated frequency for each Transmitter Loop's function (f1 to f6 as specified on the location wiring diagrams).

1.6 Measure the height of the top of the loop Below Rail Level (BRL) is within the "green" portion of the commissioning jig which reflects the tolerances specified in NR/SMS/PartZ/Z08 (Train Protection - Reference Values).

1.7 Check that the Transmitter Loop with is mounted in alignment with the track centreline.

1.8 If the Module or Transmitter Loop forms part of a Self-Powered OSS (SPOSS) then carry out NR/SMS/PartB/Test/233 (TPWS Self-Powered OSS (SPOSS) Trackside Equipment Test).

1.9 With the signal 'on', simulate a trackside equipment fault by slipping the links for the loop in the trackside apparatus case (OSS or TSS).

a) Check for correct fault indications on the affected module and in the Signal Box.

b) Remove the simulated fault.

c) Reset affected TPWS Modules.

This is done by undertaking a short (five second) isolation (disconnection of the BX110 supply fuse/link to the TPWS on the Baseplate or Trackside Enclosure).

2. Final Checks

2.1 Check that the VCR relay is energised (buffer stops only).

2.2 Check that all green 'Power' LEDs are illuminated and that all 'Fault' LED's are extinguished.

END

Includes:	TPWS Self-Powered OSS System (SPOSS)
Excludes:	All other TPWS Modules

When using the test equipment in third/fourth rail electrified areas, avoid contact between the test aerial lead and the conductor rails. Also, when using the equipment in wet conditions.

All tests requiring TPWS Transmitter Loop field strength and frequency measurements shall use a test meter approved for use with TPWS equipment.

The multimeter shall be set to a range appropriate to accurately measure frequency with a minimum resolution of 1 Hz.

All test measurements shall be recorded on the appropriate TPWS Test record card

When the power supply to TPWS is disconnected, a fault report will be indicated every time the signal displays a red aspect.

An 'affected loop' is one that is fed by a Module which has been disturbed/replaced, in which case the pair of loops associated with the Module should be tested.

An 'affected Module' includes any disturbed/replaced by the work and any associated Signalling Interface Module (and the Overspeed Sensor / Train Stop Modules fed by a disturbed/replaced Signalling Interface Module).

TEST

1. TPWS Self-Powered OSS System - Battery Test

1.1 To test battery 1, first isolate battery 2 by removing the fuse holder F2.

1.2 Press the ‘LOOP TEST’ button and Check that:

a) The green ‘TEST’ LED is illuminated for 6 seconds; and

b) The red ‘BATTERY LOW’ LED does not flash.

If the green ‘TEST’ LED does not illuminate this indicates that either Fuse 1 has ruptured or the battery is flat.

If the battery fuse has ruptured replace the fuse and re-test from step 1.1. If the battery fuse ruptures again change the SPOSM.

If the red ‘BATTERY LOW’ LED flashes during the test replace both batteries and re- test from step 1.1.

The reason for premature battery failure shall be investigated.

1.3 Re-insert the fuse holder F2.

1.4 To test battery 2 first isolate battery 1 by removing the fuse holder F1 and repeat steps 1.2 and 1.3.

2. TPWS Self-Powered OSS System – System Test.

2.1 Press the ‘SYSTEM TEST’ pushbutton on the SPOSM and Check that all LEDs illuminate (lamp test).

Illumination of all LED indicators confirms that the test sequence has started.

2.2 Depress the train detection treadle within 64 seconds and confirm that the ‘TRAIN DETECT’ green LED indicator remains illuminated while all the other indicators extinguish.

This confirms correct functionality of the train detection treadle input.

2.3 Once the ‘SYSTEM TEST’ pushbutton is pressed, the tester has 64 seconds to operate the train detection treadle and return to the SPOSM to view the indicators.

If the tester does not operate the treadle within 64 seconds the test sequence will abort and normal operation will be resumed.

Should the tester depress the treadle arm but not return to view the indicators within 64 seconds then the test sequence will have to be repeated.

2.4 64s after pressing the ‘SYSTEM TEST’ pushbutton, and provided the treadle input test is successful, the SPOSM will automatically energise the transmitter loops and complete a series of checks on the loop driver circuits and battery status.

This is identified by the green ‘TEST’ LED being illuminated for the duration of this test (6 seconds) confirming that the test is underway.

2.5 Check that none of the red ‘ARMING LOOP FAULT’, ‘TRIGGER LOOP FAULT’ or ‘BATTERY LOW’ LED indicators flash during the 6 seconds that the green ‘TEST’ indicator is illuminated.

If either of the loop fault LEDs flash then this indicates a fault in the respective loop circuit.

If the low battery LED flash this indicates the battery capacity is insufficient.

If the green ‘TEST’ LED not illuminate at all during this test then this also indicates a fault situation.

2.6 Test Mode will automatically end and normal operation will be resumed following completion of loop driver and battery tests.

2.7 To complete the transmitter loop output (voltage and frequency) tests, the SPOSM 'LOOP TEST' pushbutton shall be used to trigger the SPOSM to transmit.

Pressing the 'LOOP TEST' pushbutton will immediately start the SPOSM transmitting for 6 seconds during which time, loop measurements may be taken.

The loop test cycle will repeat continuously for as long as the 'LOOP TEST' pushbutton is held depressed.

This will provide almost continuous loop transmission with only a 375ms gap in transmission every 6 seconds.

2.8 The SPOSS Treadle shall follow standard treadle maintenance requirements as defined in NR/SMS/PartC/TQ01 (Mechanical Treadles).

3. Final Checks

3.1 Check that the VCR relay is energised (buffer stops only).

3.2 Check that all green 'Power' LEDs are illuminated and that all 'Fault' LED's are extinguished.

END

Includes:	TPWS Failure Indication Units
Excludes:	All other TPWS Modules or Units

This test is to check that the TPWS Failure Indication Unit (FIU) for use in mechanical signal boxes is functioning correctly following FIU replacement following a failure.

The test sequence checks the FIU system logic.

1. Test

Master Unit

1. With the 'NOR/ACK' switch in the NOR position, check that the Power On Lamp is illuminated and that the 'TPWS Failed' lamp is extinguished.
2. Press the indication 'Push to Test' pushbutton and check that the 'TPWS Failed' and 'Power On' lamps both flash and the audible alarm sounds.
3. Release the indication 'Push to Test' pushbutton and check that the 'TPWS Failed' lamp extinguishes and the 'Power On' lamp becomes illuminated steadily.
4. Remove the protective terminal cover from the rear of the master unit.
5. Using a digital multi meter, measure the voltage at the power supply input terminals, B12 - N12, check they lie within the range 9V DC to 15.6V DC.
6. Disconnect the wire on Terminal T1 (or T3 if 24V Fault Input is being used) and check that the 'TPWS Failed' lamp flashes and that the audible alarm sounds.
7. Turn the 'NOR/ACK' switch to ACK position and check that the 'TPWS Failed' lamp illuminates steadily and that the audible alarm silences.
8. Reconnect the wire to terminal T1 (or T3 as appropriate) and check that the 'TPWS Failed' lamp flashes but the audible alarm remains silent.
9. Turn the 'NOR/ACK' switch to NOR and check that the 'TPWS Failed' lamp extinguishes.
10. Disconnect the wire on Terminal T4 and check that the 'Power On' lamp flashes.
11. Reconnect the wire to Terminal T4 and check that the 'Power On' lamp becomes steadily illuminated.
12. Remove the termination plug from the top-most FIU and check that the audible alarm sounds.
13. Replace the termination plug and check that the audible alarm is silenced.

14. Check the security of the wiring and replace the protective terminal cover.

Slave Unit

15. With the ‘NOR/ACK’ switch in the NOR position, check that the slave unit ‘TPWS Failed’ lamp is extinguished.

16. Press the indication ‘Push to Test’ pushbutton on the associated master unit and check that the ‘TPWS Failed’ lamps flash on both the master and slave unit, the ‘Power On’ lamp on the master unit flashes and the audible alarm sounds.

17. Release the indication ‘Push to Test’ pushbutton and check that all ‘TPWS Failed’ lamps extinguish and the ‘Power On’ lamp on the master unit becomes illuminated steadily.

18. Remove the protective terminal cover from the rear of the slave unit.

19. Disconnect the wire on Terminal T1 (or T3 if 24V Fault Input is being used) and check that the slave unit ‘TPWS Failed’ lamp flashes and the audible alarm on the Master unit sounds.

20. Turn the ‘NOR/ACK’ switch to the ACK position and check that the ‘TPWS Failed’ lamp on the slave unit is steadily illuminated and that the audible alarm on the master unit is silenced.

21. Reconnect the wire to terminal T1 (or T3) and check that the ‘TPWS Failed’ lamp flashes but the audible alarm on the master unit remains silent.

22. Turn the ‘NOR/ACK’ switch to NOR and check that the ‘TPWS Failed’ lamp extinguishes.

23. Replace the protective terminal cover.

24. Repeat test on any other slave units.

END

Includes:	TPWS Buffer Stop Optimisation Project Equipment
Excludes:	All other TPWS equipment

This test is to check that the TPWS system is functioning correctly following arming loop repositioning associated with the TPWS Buffer Stop Optimisation Project.

The test sequence checks the system logic, loop power of affected units in the plane of the loop, and the transmitted power of the affected loops at 310mm above rail level. An 'affected loop' is one which has been disturbed/replaced by the work.

Prior to any work commencing, the exact position of the repositioned arming loop shall be clearly marked as detailed in the site specific method statement.

All tests requiring TPWS Transmitter Loop field strength and frequency measurements shall use a test meter approved for use with TPWS equipment. The TPWS Multimeter from Fluke is approved for such applications.

All test measurements shall be recorded on NR/SMS/PartR/TP11/RC01 (TPWS Test: Equipment Associated with Signals Record Card (Front)), together with the reason for the test “Arming Loop Re-positioned”.

A Signal Maintenance Testing Logbook entry and the TPWS Buffer Stop Optimisation Project Test Certificate shall be completed for each installation.

Prior to use, it is recommended that the TPWS Commissioning Jig is visually inspected for damage and to confirm correct alignment of the two mating halves. If a bend of more than 10mm when measured at the centre of the beam to with respect to the ends, the Commissioning Jig should not be used.

1. Test

1. Measure and record the leading edge separation distance between the arming and trigger loop on the Test Certificate.

2. Check that all loops are re-installed in the correct position to the schedule in the site specific method statement or work plan.

3. Check the affected TPWS Module LEDs by ensuring that the green ‘Power On’ LEDs and the ’Main I/P’ LEDs are alight on the affected Sensor Modules.

4. Use the TPWS calibrated test aerial to test the voltage received by the aerial and the frequency of the signal received at the arming transmitter loop.

   The voltage shall be greater than 4.26mV AC see NR/SMS/PartZ/Z08 (Train Protection - Reference Values) for values. To measure the voltage, the TPWS test aerial shall be positioned centrally above the plane of the loop using the Commissioning Jig and recorded to the 5 digit capability of the multimeter.

When taking measurements, the meter shall not be held over the loops, to avoid interference from the loop field. It shall instead be held as far outside of the rails as the test aerial lead allows, as shown in NR/SMS/PartB/Test/232 (TPWS Module or Transmitter Loop Test (following P Way Work).

Use the TPWS calibrated test aerial to test the voltage received by the aerial and the frequency of the signal received at the arming transmitter loop.

The voltage should be between 59mV and 107mV AC for Buffer Stop Mini-Loops, and the frequency within +/-0.01kHz of the stated frequency (as specified on the location wiring diagrams).

To measure the voltage and frequency, the TPWS test aerial shall be positioned centrally within the plane of the loop using the Maintenance Jig and recorded to the 5 digit capability of the multimeter.

When taking measurements, the meter shall not be held over the loops, to avoid interference from the loop field.

It shall instead be held as far outside of the rails as the test aerial lead allows, as shown in NR/SMS/Part03/Test/231 (TPWS Module or Transmitter Loop Test (following failure).

5. Measure the height of the top of the loop Below Rail Level (BRL) and check that it is within the tolerances specified in NR/SMS/PartZ/Z03 (Train Detection Reference Values).

6. Measure the height of the loop above the sleeper and check that it is within the following tolerances:

   For loops mounted on steel sleepers check the loop is a minimum of 70mm above the top surface of the sleeper.

   For loops mounted on concrete slab track check the loop is a minimum of 50mm above the top surface of the sleeper.

7. Check that the centre line of the Transmitter Loop is within 10mm of the centre line of the track.

8. Check that tamper-proof seals are intact of the Thales pre-wired equipment.

9. De-energise the affect loops by slipping links to the loop output circuit and check for correct fault indications on the affected module and in the signal box (if provided). Remove the simulated fault.

10. Reset affected TPWS Modules by undertaking a short term isolation (disconnection of the BX110 supply fuse/link to the TPWS on the Baseplate or Trackside Enclosure) for five seconds.

This shall be done with the main signal ‘off’ to clear any fault indication.

11. Check that isolation fuses/links are in the correct position and that screw terminals are tight.

12. Record the values on the maintenance record card, see NR/SMS/PartR/Index.

END

Includes:	Primary Cell Fed, TJ/Secondary Cell Fed, Feed set Fed, AC immune and non- immune
Excludes:	All other types of track circuit

GENERAL

DC track circuits fed from primary cells usually tend to have low feed voltages, feed resistance, rail voltage, relay resistance and operating values. This is a design trait to conserve the limited life of power available from a primary cell.

Track circuits fed indirectly from mains supplies will have higher values of those mentioned which improves reliability and detection under poorer conditions (rusty rails, low ballast resistance etc).

Design improvements have also led to systems that require no feed resistance adjustment and have immunity to AC interference.

A faulting guide and adjustment details for this type of track circuit can be found in NR/SMTH/Part10/FF02 (Faulting Guide: DC Track Circuits).

1. Maintenance Test

Feed End

1.1 Measure and record the DC voltage across the rails.

Feed End Relay (If fitted)

1.2 Connect a train shunt across the track links. Obtain a drop shunt and pick up shunt value. Disconnect the shunt box.

If the track links are not accessible, connect the train shunt across the rails.

If the drop shunt is lower than the minimum value NR/SMS/PartZ/Z03 (Train Detection - Reference Values) carry out the full test.

Relay End

1.3 Measure and record the DC voltage across the energised track relay coil.

1.4 Connect a train shunt across the track links. Obtain a drop shunt and pick up shunt value. Disconnect the train shunt.

If the track links are not accessible, connect the train shunt across the rails.

If the drop shunt is lower than the minimum value NR/SMS/PartZ/Z03 (Train Detection - Reference Values) carry out the Full Test.

Where a feed end relay is also provided, carry out this test by observing the relay end track relay.

1.5 Assess the condition of ballast/ground conditions.

1.6 Record the results on the record card.

1.7 Compare results with previous records for any significant variations. Where there is a significant variation in values, retest with the train shunt applied to the rails.

If any adjustments are carried out a Full Test shall be carried completed.

A variation in drop shunt value can be caused by variations in the equipment or environment.

In wet conditions, a higher value of drop shunt can be expected. In dry or icy conditions, a lower value can be obtained. Poor ballast conditions can also affect the value of the drop shunt.

2. Full Test

The full test should be carried out whenever alterations are made including relaying, lead/jumper renewal, equipment replacement, adjustment etc.

Feed End

2.1 Measure the feed voltages, currents and other parameters as required on the record card.

Feed End Relay (If fitted)

2.2 Connect a train shunt across the rails. Obtain a drop shunt and pick up shunt value. Disconnect the shunt box.

If the drop shunt is lower than the minimum value NR/SMS/PartZ/Z03 (Train Detection - Reference Values) the track circuit shall be regarded as failed and the cause shall be investigated.

Relay End

2.3 Measure the relay voltages, currents and other parameters as required on the record card.

2.4 Measure the DC voltage on the track relay coil.

2.5 Connect a shunt box across the rails. Obtain a drop shunt and pick up shunt value. Disconnect the shunt box.

If the drop shunt is lower than the minimum value (NR/SMS/Part/Z03 (Train Detection - Reference Values) the track circuit shall be regarded as failed and the cause shall be investigated.

Where a feed end relay is also provided, carry out this test by observing the relay end track relay.

2.6 With the train shunt set to 0.5Ω, apply the shunt across the rails at all the extremities of the track circuit. Check that the track relay drops sharply.

2.7 Assess the condition of ballast/ground conditions.

2.8 Record the results on the record card. Compare results with previous records for significant variation.

Where there is a significant variation in values the cause shall be investigated and rectified. The Full Test shall then be carried out again.

Remember to take into account weather and ballast conditions.

3. Residual Voltage Check

This check is not required if the track circuit is fitted with a feed end relay.

3.1 Measure the drop away and pick up voltages of the track circuit at the relay end.

A 150kΩ shunt should be used when testing with a fluke meter.

3.2 Disconnect the feed end track links.

3.3 After a period of 120 seconds, measure the voltage across the coils of the track relay. This voltage shall be compared to the voltages recorded in 3.1.

If the recorded voltage is:

a) Greater than 30% (but less than 70%) of the minimum drop away voltage, report immediately to the SM(S).

If the voltage does not exceed 70% of the minimum drop away voltage, the S&TME can authorise the track circuit to remain in service provided that any jumpers in the bonding, including fishplates and other types of bonding are duplicated, and all types of bonding are inspected at 4 weekly intervals.

Plain Line TCs with no jumpers can be inspected at 13 weekly intervals.

This is to allow time for corrective maintenance actions to be undertaken to identify and eliminate the source of the residual voltage or other measures such as replacement of rail pads and insulations on concrete sleepers and slab track to be undertaken.

Such actions shall normally be completed within 12 Months.

b) Greater than 70% of the minimum drop away, the track circuit shall not remain in service unless the S&TME can confirm that a Risk Assessment and Time Bound Action Plan has been submitted and authorised by the RAM(S).

The S&TME shall keep a register of all track circuits where residual voltages exceed 30% of the minimum drop away Voltage.

END

Includes:	EBI Track 200 Audio Frequency Track Circuit (formally known as TI21) and Aster21
Excludes:	All other Track Circuits

The Aster21 Application is detailed in NR Standard NR/L2/SIG/11766 which defines that the EBI Track 200 SMS covers Aster21 with the exception that the relay drive is 24VDC for Aster21.

1. Maintenance Test A1

Feed (Transmitter) End

1.1 Check all rail connections and bonding are tightened to the correct torque. (Appendix F of NR/SMS/Appendix/08).

Impedance Bonds (where fitted)

1.2 Check the impedance bond for the following:

a) Bond Covers correctly fitted and not damaged.

b) Drain holes clear (on Howells & WH3 bonds).

It might be necessary to drill drain holes if they are not present. (Pre installation check).

c) Tuning capacitor or tuning module connections.

1.3 Check all rail connections and bonding are tightened to the correct torque (Appendix F of NR/SMS/Appendix/08).

Relay (Receiver) End

1.4 Check all rail connections and bonding are tightened to the correct torque (Appendix F of NR/SMS/Appendix/08).

1.5 Measure the rail-to-rail voltage at the EBI Track 200 equipment rail connections (Pole) using a TTM/MTM (Vp, (Appendix F of NR/SMS/Appendix/08).

For consistency, this measurement shall always be carried out at the rails.

1.6 Measure the rail current in the rail within 1 metre and on the track circuit side of the rail connections with a Rocoil.

For a Single Rail track circuit the measurement shall be made in the Signal rail.

1.7 Where a tuned zone is involved, Measure using a FSM/MTM the rail-to-rail voltage at the companion TU rail connection (Zero) at the frequency of the track circuit under test. (Vz).

The voltage measured in 1.5 (Vp Pole) divided by the voltage at the companion TU (Vz Zero) gives the Tuned Zone ratio (Tzr) where Tzr = Vp/Vz.

Check the ratio against Appendix B of NR/SMS/Appendix/08. If the ratio is below specification, the low result usually relates to badly dressed cables and or poor connections, therefore, Check that the cables are dressed correctly and that all Tuning units' connection are correct, clean and tight.

1.8 If a digital receiver is in use, Check the display for a steady 'PICK' or 'drop' indication. If one of these indications cycles with the indication 'ERR' then refer to Appendix E4 of NR/SMS/Appendix/08 and investigate the reason for the error. An 'ERR' state shall not be left without authority from the SM(S).

A significant deviation is indicated if the change of track current is greater than:

a) ±20% OR
b) ±10mA.

On The Receiver

Press OK then 'NEXT' until 'INOW'

Press OK then Next Until 'USB'

Press OK and note the value

Press 'BACK' then 'NEXT' until 'LSB'

Press OK and note the value

Calculate and record sideband imbalance by dividing the larger value by the smaller value.

If the sideband imbalance exceeds the ratio values above, the track circuit shall be investigated to ascertain the cause of the imbalance. Carry out steps 2.4.7 to 2.4.11 of NR/SMS/Appendix/08.

1.9 For Analogue receivers Measure the voltage across the 1Ω resistor; compare this reading against the Record Card.

For Digital receivers Record the Inow AV current using the display on the receiver and compare this reading against the Record Card.

If the obtained reading is not within 10% of the Commissioning reading or last Set-up reading on the Record Card, the reason for the discrepancy shall be investigated.

If adjustment is required, the initial setting for an analogue RX shall be selected from Appendix D Table D1 of NR/SMS/Appendix/08 using the voltage across the

1Ω resistor, followed by a drop shunt test. For digital RX, an auto-set routine shall be performed. (See Appendix E of NR/SMS/Appendix/08)

The RX current is the best measure of the track circuits' stability. Significant deviations from previous readings shall be investigated.

For track circuits which continually give problems, the frequency of checking the receiver current might need to be increased to help in diagnosing the cause of any issues.

A significant change shall be determined by which is the greater of :

a) ±20% OR
b) ±10mA.

1.10 Record the ballast and weather conditions on the track circuit Record Card.

1.11 Using a shunt applied to the rails between the RX tuning unit rail connections obtain a drop shunt value and a pick up shunt value.

Shunt Box and Connection Verification Check
Connect a shunt box across the rails at the receiver TU or ETU track connections.
Set the drop shunt to 0.0Ω.
Check that clear track current (INOW) has fallen to less than 5mA.

If the readings are equal to or higher then 5mA then the Shunt Box, meter leads and connections should be checked to confirm it is giving a 0.0Ω shunt.

Shunt values are detailed in NR/SMS/Part/Z03.

On the pick-up shunt, allow 2 seconds between each value to allow the slow to pick relay drive from the RX to operate.

The pick-up value should normally be 0.1Ω higher than the drop shunt.

Compare the results with previous records (if available) obtained under similar conditions. If the results are not within ±10% the cause shall be investigated and rectified as appropriate. A FULL TEST shall then be carried out.

2. Full Test

2.1 Examine the track circuit in accordance with NR/SMS/TC16 service A.

Feed (Transmitter) End (Digital TX and Analogue TX)

2.2 Examine the TX unit case, connector and terminations and check the plug coupler is pushed fully home. Also check the plug coupler on any PSUs, TCUs or LMUs used are also pushed fully home.

2.3 Regardless of the supply voltage Check/Set the PSU input tappings to P5 and P115.

For Analogue Transmitters:

Measure the input and output voltages of the power supply.

These should be in the range of:

a) Input: 99V to 121V AC
b) Output: 22.5V to 30.5V DC

For Digital Transmitters:

Measure the input voltage of the power supply.

If the supply is over 115VAC, adjust the PSU output tappings to give between 25V DC and 27V DC. Otherwise, adjust the PSU output tappings to give ideally 24V – 26V DC.

Digital TX of MOD strike 2 may show a red POWER LED indication if the power supply voltage is over 27V DC. This can be ignored provided that the TX has been set up as stated above.

Digital TX of MOD strike 2 to 4 will shut down at 30.5V DC therefore it is important to check the voltage is kept below this threshold.

Record the PSU Output Voltage

2.4 Measure the DC current drawn by the equipment.

a) Normal Power 1.3A to 2.2A.
b) Low Power/TCU 0.2A to 0.5A
c) Low Power Plus 0.2A to 0.55A

2.5 Measure the total AC+DC current drawn by the equipment. If the measured value is 20% above the expected maximum value (i.e. 2.6A for Normal Power TX, 0.6A for Low Power TX, 0.65A for Low Power Plus TX) then investigate from where this additional current is being generated.

2.6 Measure the TX output voltage across terminals OP/1 and OP/2 using a TTM.

For Analogue Transmitters the voltages should be:

a) Frequencies A, C, E, G: 10V – 11V RMS
b) Frequencies B, D, F, H: 15V – 16V RMS

For Digital Transmitters

c) 8.5V to 12.5V RMS regardless of frequency.

For either type of transmitter, when connected in low power mode or low power plus mode, the output voltage may be up to 5V RMS higher than in normal power.

2.7 Measure the rail-to-rail voltage at the TU (Pole) or ETU rail connections using a FSM/TTM (Vp, Appendix A of NR/SMS/Appendix/08).

For a TCU system refer to the low power figures.

For consistency this measurement shall always be carried out at the rails.

2.8 Measure the rail current in the rail within 1 metre and on the track circuit side of the rail connections with a Rocoil.

For a Single Rail track circuit the measurement shall be made in the Signal rail.

2.9 Where a tuned zone is involved, Measure using a FSM/TTM the rail-to-rail voltage at the companion TU rail connection (Zero) at the frequency of the track circuit under test. (Vz).

The voltage measured in 3.7 (Vp Pole) divided by the voltage at the companion TU (Vz Zero) gives the Tuned Zone ratio (Tzr) where Tzr = Vp/Vz.

Check the ratio against Appendix B of NR/SMS/Appendix/08. If the ratio is below specification, Check that the cables are routed correctly and that all Tuning Unit connections are correct, clean and tight.

Impedance Bond and Track Capacitors (Where fitted)

The impedance of an impedance bond can be checked by measuring the EBI Track 200 voltage across the bond and the current through it. To take the current measurements use a Rocoil connected to a TTM.

2.10 Check all rail connections and bonding are tightened to the correct torque (Appendix F of NR/SMS/Appendix/08).

2.11 Check the security and the fixing of the Track capacitor.

2.12 Measure using a FSM/TTM the rail-to-rail voltage.

Clauses 2.13 and 2.14 are not applicable to B3 3000 and B3 500 bonds.

2.13 Measure the voltage across the auxiliary coil or tuning module, Check it is in the correct ratio with the rail-to-rail voltage (Appendix C of NR/SMS/Appendix/08). If it is not the impedance bond shall be investigated for a fault.

2.14 Apply a short circuit across the tuning capacitor/module, Check that the rail voltage falls then remove the short circuit and Check the voltage rises.

Clauses 2.15 to 2.19 are applicable to Intermediate bonds only.

2.15 Place the Rocoil over the rail 1 metre before the Bond (TX side) and note the reading on the TTM (= amps, I1).

2.16 Repeat the measurement 1 metre from the bond on the RX side (I2)

2.17 Subtract I2 from I1 obtaining the current through the bond at the EBI Track 200 frequency.

2.18 Measure the rail to rail voltage (V) across the impedance bond.

2.19 Divide the voltage (V) by the current calculated from 2.17 giving the impedance (Z), Z= V / (I1-I2).

This value should be greater than 8Ω. If less than 8Ω, Check for traction imbalance before remedial action is taken with the impedance bond.

Relay (Receiver) End

2.20 Examine the RX unit case, connectors and terminations and check the plug coupler is pushed fully home. Also check the plug coupler on any PSUs, TCUs or LMUs used are also pushed fully home.

2.21 Measure the input and output voltages of the power supply

a) Input: 99V to 121V AC
b) Output: 22.5V to 30.5V DC

The output voltage should be close to 24V unless there is reason to believe that the I/P conditions are unusual, in which case the input tapping should be adjusted to 120 volts

2.22 Measure the DC current drawn by the equipment.

a) 0.2A to 0.5A.

2.23 Measure the total AC+DC current drawn by the equipment. If the measured value is 20% above the expected maximum value (i.e. 0.6A for RX) then investigate from where this additional current is being generated.

2.24 If a digital receiver is in use, Check the display for a steady ‘PICK’ or ‘drop’ indication. If one of these indications cycles with the indication ‘ERR’ then refer to Appendix E4 of NR/SMS/Appendix/08 and investigate the reason for the error. An ‘ERR’ state shall not be left without authority from the SM(S).

2.25 If a digital receiver is in use, confirm the track circuit has a Sideband imbalance ratio less than:

a) 1.6:1 for TU/ETU/SPETU
b) 1.8:1 for TCU

On The Receiver

Press OK then 'NEXT' until 'INOW'

Press OK then Next Until 'USB'

Press OK and note the value.

Press 'BACK' then 'NEXT' until 'LSB'

Press OK and note the value.

Calculate and record sideband imbalance by dividing the larger value by the smaller value.

If the sideband imbalance exceeds the ratio values above, the track circuit should be investigated to ascertain the cause of the imbalance. Carry out steps 2.4.7 to 2.4.11 of NR/SMS/Appendix/08.

2.26 Measure the rail-to-rail voltage at the TU (Pole) or ETU rail connections using a FSM/TTM (Vp Appendix A of NR/SMS/Appendix/08).

For a TCU system refer to the low power figures.

For consistency this measurement shall always be carried out at the rails.

2.27 Measure the rail current in the rail within 1 metre and on the track circuit side of the rail connections with a Rocoil.

For a Single Rail track circuit the measurement shall be made in the Signal rail.

Low rail volts or rail current could be due to ballast or other track equipment, as well as a fault at the TX end of the track.

2.28 Where a tuned zone is involved, Measure using a FSM/TTM the rail-to-rail voltage at the companion TU rail connection (Zero) at the frequency of the track circuit under test. (Vz).

The voltage measured in 2.26 (Vp Pole) divided by the voltage at the companion TU (Vz Zero) gives the Tuned Zone ratio (Tzr) where Tzr = Vp/Vz.

Check the ratio against Appendix B of NR/SMS/Appendix/08. If the ratio is below specification, the low result usually relates to badly dressed cables and or poor connections, therefore, Check that the cables are dressed correctly and that all Tuning units' connection are correct, clean and tight.

2.29 For Analogue receivers Measure the voltage across the 1Ω resistor; compare this reading against the Record Card.

For Digital receivers Record the Inow AV current using the display on the receiver and compare this reading against the Record Card.

If the obtained reading is not within 10% of the Commissioning reading or last Set-up reading on the Record Card, the reason for the discrepancy shall be investigated.

If adjustment is required, the initial setting for an analogue RX shall be selected from Appendix D Table D1 of NR/SMS/Appendix/08 using the voltage across the 1Ω resistor, followed by a drop shunt test. For digital RX, an auto-set routine shall be performed.

The RX current is the best measure of the track circuits' stability. Significant deviations from previous readings shall be investigated.

A significant deviation is indicated if the change of track current is greater than:

a) ±20% OR
b) ±10mA.

2.30 Measure the voltage across the energised track relay coils.

a) 40V to 75V DC for the analogue RX
b) 40V to 44V DC for the digital RX MOD 1 & 2
c) 48V to 52V DC for the digital RX MOD 3 or later

Aster21 Receivers are configured for 24VDC relay drive therefore the voltage across the energised track relay coils will be 20V to 26V DC.

2.31 Using a train shunt applied to the rails between the RX tuning unit rail connections obtain a drop shunt value and a pick up shunt value.

Shunt Box and Connection Verification Check
Connect a shunt box across the rails at the receiver TU or ETU track connections.
Set the drop shunt to 0.0Ω.
Check that clear track current (INOW) has fallen to less than 5mA.

If the readings are equal to or higher then 5mA then the Shunt Box, meter leads and connections should be checked to confirm it is giving a 0.0Ω shunt.

Shunt values are detailed in NR/SMS/Part/Z03.

On the pick-up shunt allow 2 seconds between each value to allow the slow to pick receiver relay drive to operate.

2.32 Compare the results with previous records (if available) obtained under similar conditions. If the results are not similar the cause shall be investigated and rectified as appropriate. The FULL TEST shall then be repeated.

2.33 Record the ballast and weather conditions on the track circuit Record Card.

Interference Test

Check that all tracks in vicinity of track to be tested are energised and working

This test checks the levels of in band and traction interference present at the RX, and requires temporary disconnection of the TX.

Check the fusing arrangements before this test as more than one track circuit might be affected.

2.34 Remove the B24 fuse to the TX and Check that the correct track relay drops. Set the TTM to the 20mV range (30mV range for FSM) and the frequency to that of the track circuit under test. Measure the voltage across the 1Ω resistor at the RX.

Readings greater than 8mV for double rail tracks and greater than 3mV for single rail tracks are un-acceptable, the track circuit shall be signed out of use and your SM(S) informed.

Where a digital RX is in use, these readings as currents, can be read directly from the RX display where they are displayed in mA. Since the Voltage reading above is taken across a 1Ω resistor the mA reading directly equates to the mV reading.

Extremity Tests

2.35 Apply a shunt at the extremities of the track circuit, in accordance with the track plan, and Check the track relay drops for each application.

Minimum Shunt values are detailed in NR/SMS/Part/Z03.

End

Includes:	SF15 / U Type Aster track circuits
Excludes:	Aster 21, EBI Track 200 (formally known as TI21) and EBI Track 400. All other types of track

General

The TX and RX shall not be disconnected at the same time.

As this could result in an adjacent track circuit feeding through and causing a possible wrong side failure.

Centre Fed Track Circuits

Each half of a centre fed track circuit operates as an independent track circuit and should be tested as such. Record cards should be kept for each part.

Cut Section Track Circuits

Each cut section should be treated as an individual track circuit and record cards kept accordingly.

Disconnection of Units

The Tx and Rx should not be disconnected at the same time as this could results in an adjacent track circuit feeding through and causing a possible wrong side failure.

Test Equipment

A frequency selective meter (FSM), or TI21 Test Meter (TTM), set to the frequency of the track circuit under test.

Gain Settings

The gain setting shall not be increased without consulting your SM(S).

Tuned Zones

These shall be kept clear of all metallic objects including new or scrap lengths of rail for a distance of at least 1.25m (4ft).

The tail cables from the TU/ACT to the rails form part of the tuned circuit, because of this they should be bound together wherever possible, not allowed to form loops and not be run in parallel with the running rails.

Failure to observe these items can result in the effectiveness of the tuned area being altered.

Bonded Rail Joints

Bonds across rail joints should be of a low resistance as this can influence the characteristics of the track circuit.

1. Maintenance Test

Relay (Receiver) End

1.1 Measure and record at the power supply (T/J or Charger) the AC input voltage and the DC output voltage (between 22.5V and 29.5V).

1.2 Measure and record at the receiver unit the AC input voltage between T1 and T2.

1.3 Where a tuned zone is involved.

a) Measure the rail-to-rail voltage at the TU rail connections using a FSM/TTM

b) Measure the rail-to-rail voltage at the adjacent TU rail connection at the frequency of the track circuit under test.

The ratio between these two measurements should be compared to the table in Appendix C.

1.4 Apply a train shunt across the rails at the tuning unit and obtain a drop shunt and a pick-up shunt.

The test results where the receiver is adjacent to a pair of insulated rail joints shall be compared to the table in Appendix B.

For shunt values refer to NR/SMS/PartZ/Z03 (Train Detection - Reference Values).

1.5 With the track circuit not shunted by trains or a train shunt, measure the DC voltage across the track relay coil terminals R1(+) and R2(-).

2. Full Test

The full test should be carried out whenever alterations are made including; relaying, lead/ jumper renewal, equipment replacement, adjustment etc). The full test should also follow the clearing of a fault.

All measurements taken at track circuit frequency are to be taken using a frequency selective meter.

The minimum drop shunt value with the train shunt applied across the rails at the transmitter-tuning unit is 0.3Ω.

2.1 Examine the track circuit in accordance with NR/SMS/PartC/TC10 (Track Circuits: Aster SF15 / U Type) - Service A.

Feed (Transmitter) End

2.2 Measure and record at the power supply (T/J or Charger) the AC input voltage and the DC output voltage (between 22.5V and 29.5V).

2.3 Measure and record at the transmitter unit the AC output voltage between terminals 1&2 or 1&3 and measure the AC feedback voltage between T1&T2.

2.4 Measure and record at the tuning unit the AC voltage between T1&T2. Check they are as follows:

TU Voltage (T1/T2)		
TC Length	Min	Max
50m	1.6V	2.7V
1000m	2.5V	5.3V

Table 1 – TU Voltages

2.5 Measure the rail-to-rail voltage at the TU rail connections using a FSM/TTM. For consistency this measurement shall always be carried out at the rails.

2.6 Where a tuned zone is involved.

a) Measure the rail-to-rail voltage at the TU rail connections using a FSM/TTM,

b) then measure the rail-to-rail voltage at the adjacent TU rail connection at the frequency of the track circuit under test.

The ratio between these two measurements shall be compared to the table in Appendix C.

Relay (Receiver) End

2.7 Measure and record at the power supply (T/J or Charger) the AC input voltage and the DC output voltage (between 22.5V and 29.5V).

2.8 Check the tappings REC1, REC2 and straps A/-/H on the receiver unit for the track circuit length (Appendix A).

NOTE: *The tappings are only a guide and adjustment to obtain satisfactory shunts should always take priority.*

2.9 Measure and record at the receiver unit the AC input voltage between T1 and T2.

2.10 Measure and record at the tuning unit the AC voltage between T1 and T2. Check they are as follows:

TU Voltage (T1/T2)		
TC Length	Min	Max
50m	1.7V	2.8V
1000m	0.25V	0.8V

Table 2 - AC Voltages

2.11 Measure and record the rail-to-rail voltage at the TU rail connections using a FSM/TTM. For consistency this measurement shall always be carried out at the rails.

2.12 Where a tuned zone is involved.

a) Measure the rail-to-rail voltage at the TU rail connections using a FSM/TTM.

b) Measure the rail-to-rail voltage at the adjacent TU rail connection at the frequency of the track circuit under test.

The ratio between these two measurements should be compared to the table in Appendix C.

2.13 Apply a train shunt across the rails at the tuning unit and obtain a drop shunt and a pick-up shunt.

2.14 The test results where the receiver is adjacent to a pair of insulated rail joints should be compared to the table in Appendix B.

For shunt values refer to NR/SMS/PartZ/Z03 (Train Detection - Reference Values).

2.15 Train Shunt Test all extremities of the track circuit. This test should also obtain simultaneous track circuit occupation where an overlapping section exists.

2.16 With the track circuit not shunted by trains or a train shunt, measure the DC voltage across the track relay coil terminals R1(+) and R2(-) and the tuning unit input voltage between T1 and T2.

2.17 Apply a train shunt to the tuning unit terminalsT1 & T2 and obtain a drop shunt and pick up.

2.18 Record the obtained results and other details along with the latest setting numbers on the paper or digital record card.

Where the Receiver Is Adjacent to A Pair of Insulated Rail Joints

2.19 Report situations where track circuit track tail cables are not terminated within 1m of an IRJ.

2.20 Drop shunt test at three positions approximately 15m apart, within 50m of transmitter and its terminations. For a feed end the test should be outside the tuned zone. Results are listed in Appendix B.

Interference Test

2.21 Remove the B24 fuse to the Tx and check the track relay drops. Set a frequency selective meter to the frequency of the track circuit under test and measure the AC input voltage at the Rx unit between T1 and T2.

2.22 Compare this voltage with the one obtained in 2.9, if it is greater than 25% of this voltage, the track circuit shall be signed out of use and your supervisor informed immediately.

Table 3 - Receiver Gain Connections

The receiver gain connections listed above are to be used as a guide.

Adjustment can be required to suit local conditions.

APPENDIX B - Test Results Where the Receiver Is Adjacent to A Pair of Insulated Rail Joints

Where the drop shunt values below 0.5W (0.7W when wet):

- Inform your SM(S).
- Reduce the gain on the receiver and retest. If unsatisfactory, arrange for the receiver and tuning units to be replaced.

Track circuits that cannot be properly adjusted should be advised to the Signaller.

APPENDIX C - Tuned Zone Ratios

Ratio	Action
2:1 or less	The relevant tuning unit shall be replaced within 48 hours
Between 3:1 & 2:1	IF the other end of the TC not under test is formed of a tuned zone, test the Tuned Zone Ratio at the far end and if that is less than 5:1, replace the tuning unit with the lower Tuned Zone Ratio value
Above 3:1	No action

Table 4 - Tuned Zone Ratios

END

Includes:	HVI Track Circuit equipment
Excludes:	All other Track Circuit types

GENERAL

Red bonds are very dangerous if they become disconnected. Never touch them as there could be a dangerous voltage. Report to E.C.O any found.

In 3rd rail DC traction areas and in dual electrified areas (3rd rail DC and AC overhead line) HVI track circuit transformer/terminal boxes (known as 'bread bins') can experience a catastrophic arcing across the terminals when the 3rd rail DC traction supply is short circuited to the 'signalling' rail.

As these traction short circuits can be unpredictable (they can be caused by trains, conductive rubbish etc) no preventative or corrective maintenance shall be undertaken inside the 'bread bin' with the 3rd rail DC traction current energised.

If preventative or corrective maintenance requires access inside the 'bread bin' the 3rd rail DC traction current shall be isolated for the entire length of the track circuit(s) concerned. Alternatively remove all track leads, including any adjacent leads that are housed in the same bread bin. Measurements shall be taken on the rails.

In 3rd rail DC traction supply areas where track access can be restricted, there can be permanent 'test leads' installed from the rails to a special test box in a position of safety. In this situation the terminations in the test box may be used to obtain measurements where the test asks for readings 'on the rails'.

The resistance of the test leads (stated on the test box) shall be taken into account when obtaining measurements by this method.

This does not apply in non-electrified areas or if the traction supply is by AC overhead line only.

The tests are marked with a # symbol, only the tests applicable to the traction current supply in the area of the track circuit shall be carried out. If you are unsure, ask your SM(S).

# Symbol	Meaning
#1	Non-electrified areas and overhead line (AC & DC) areas only
#2	3rd rail DC traction areas and dual supply traction areas (3rd rail and overhead line) only
#3	All areas

NOTE: *A faulting guide and adjustment details for this type of track circuit can be found in NR/SMTH/Part10/FF06 Faulting Guide: High Voltage Impulse (HVI) Track Circuits*

1. Maintenance test

1.1 #1 Drop Shunt Test (T1): Using a shunt box, carry out a drop shunt test at the relay end track transformer track terminals.

The drop shunt values can be found in NR/SMS/PartZ/Z03 (Train Detection – Reference Values).

1.2 #2 Drop Shunt Test (T2): Using a shunt box, carry out a drop shunt test at the relay end on the rails.

1.3 #3 Track Relay Voltage Test (T3): Using a digital voltmeter set on DC manual range, measure the voltage at the track relay plug board contacts.

There will be a fluctuation in the reading.

Electrified and Non-Electrified Lines	
V1+ to V1-	**V2+ to V2-**
Min 20V	Min 30V
Max 50V	Max100V

1.4 #1 Relay End Track Transformer Voltage (T4): Measure the relay voltage at track relay end track transformer track terminals, using adapter integrator with a digital voltmeter on auto range.

1.5 #2 Relay End Track Transformer Voltage (T4): Measure the relay voltage at track relay end on the rails, using adapter integrator with a digital voltmeter on auto range.

Polarity Ratio +ve : -ve	**Electrified Lines**		**Non- Electrified Lines**	
	V+ to V-		**VA to VB**	
	Min 50V	Max 150V	Min 20V	Max 120V
Min 5:1 Max 10:1	Min 8V	Max 22V	Min 2V	Max 12V

1.6 #1 Relay End Load Test (T5): Load test at relay end track transformer track terminals with a 0.5Ω shunt across the rails, using adaptor integrator.

1.7 #2 Relay End Load Test (T5): Load test at relay end with a 0.5Ω shunt across the rails, using adaptor integrator.

Electrified Lines	**Non-Electrified Lines**
V+ to V-	**VA to VB**
Min 10V	Min 6V

2. Full Test

2.1 #1 Drop Shunt Tests (T1 & T2): Using a shunt box, carry out a drop shunt test at the relay end track transformer terminals and on the rails.

The drop shunt values can be found in NR/SMS/PartZ/Z03 (Train Detection – Reference Values).

2.2 #2 Drop Shunt Tests (T2): Using a shunt box, carry out a drop shunt test at the relay end rails.

2.3 #3 Track Relay Voltage Test (T3): Using a digital voltmeter set on dc manual range, measure the voltage at the track relay plugboard contacts.

There will be a fluctuation in the reading.

Electrified and Non-Electrified Lines	
V1+ to V1-	**V2+ to V2-**
Min 20V	Min 30V
Max 50V	Max100V

2.4 #1 Relay End Track Transformer Voltage (T4): Measure the relay voltage at track relay end track transformer track terminals, using adapter integrator with a digital voltmeter on auto range.

2.5 #2 Relay End Track Transformer Voltage (T4): Measure the relay voltage at track relay end on the rails, using adapter integrator with a digital voltmeter on auto range.

Polarity Ratio +ve : -ve	**Electrified Lines**	**Non- Electrified Lines**
	V+ to V-	**VA to VB**
	Min 50V Max 150V	Min 20V Max 120V
Min 5:1	Min 8V Max 22V	Min 2V Max 12V

2.6 #1 Relay End Load Test (T5): Load test at the relay end track transformer track terminals with a 0.5Ω shunt across the track terminals, using adaptor integrator.

2.7 #2 Relay End Load Test (T5): Load test at relay end track transformer track terminals with 0.5Ω shunt across the rails, using adaptor integrator.

Electrified Lines	**Non-Electrified Lines**
V+ to V-	**VA to VB**
Min 10V	Min 6V

2.8 #3 Power Supply Test (T6): Measure the power supply voltage and current, under full working load using a digital meter.

Electrified and Non-Electrified Lines	
Voltage Parameters	**Current Parameters**
Min 95V Max 121V	Min 0.3A Max 0.5A

2.9 #3 Transmitter Power Test (T7): (To be completed within 2 minutes)

a) Connect a short circuit between transmitter terminals C- and t6. Disconnect any strapping between t1 and t6.

If any terminal other than t6 is connected to outgoing links, remove the links.

b) Using the Adapter Integrator and a digital meter measure the transmitter power between terminals 1 (+ve) & 3 (-ve) of the transmitter.

c) Reconnect terminals and links.

Electrified and Non-Electrified Lines
Minimum 120V

2.10 #1 Feed End Voltage Test (T8): Measure feed voltage at feed end track transformer track terminals, using adapter integrator with a digital voltmeter on auto range.

2.11 #2 Feed End Voltage Test (T8): Measure feed voltage at feed end, on the rails, using adapter integrator with a digital voltmeter on auto range.

Polarity Ratio +ve : -ve		**Electrified Lines**		**Non- Electrified Lines**	
		V+ to V-		**VA to VC**	
		Min 50V	Max 150V	Min 20V	Max 120V
Min 5:1	Max 10:1	Min 8V	Max 22V	Min 2V	Max 12V

2.12 #3 Pulse Rate Test (T9): Touch the rear casing of the feed end track transformer and count the number of pulses.

Electrified and Non-Electrified Lines	
Number of Pulses in 7 Seconds	
Min 15	Max 30

2.13 #3 Un-shunted External Interference Test (T10): Disconnect the PSU fuses and using a digital voltmeter set to DC manual range. Measure the voltage at track relay terminals. Reconnect the PSU fuses.

Electrified Lines	**Non-Electrified Lines**
V2+ to V2-	
Max 10V	Max 6V

2.14 #3 Shunted External Interference Test (T11): Disconnect the PSU fuses and Connect a short circuit across the feed end transformer V+V-. Using a digital voltmeter set to DC manual range; Measure the voltage at track relay terminals. Reconnect the PSU fuses and remove the short circuit.

Electrified and Non-Electrified Lines
V2+ to V2-
Max 7V

END

Includes:	BR-WR Quick Release Track Circuit equipment
Excludes:	All other Track Circuit types

There is no simple relationship between the drop shunt value across the rails and the drop shunt value across the relay (the track relay being remote from the rails and associated transformer-rectifier).

If the voltage across the relay at drop away does not vary on subsequent maintenance tests by more than the percentage permitted, this can be considered a valid drop shunt test for this type of track circuit.

1 Maintenance test

1.1 Carry out a drop shunt test.

Where this is not practicable because the TR is remote from the rails, the following test can be used as an alternative.

a) At the relay end of the track circuit with the train shunt applied across the relay end links, obtain the drop away voltage value across the relay coils.

Details of drop shunt values are in NR/SMS/Part/Z03.

The variation of the drop away voltage should not exceed +/ 10% of the voltage recorded at the last FULL TEST of the track circuit. If the variation exceeds these limits the shunt value shall be determined by a FULL TEST.

1.2 Measure the voltage across the track relay coil with the track circuit clear of trains and train shunt.

1.3 Assess the condition of the ballast.

1.4 Record all test results on the paper or digital record card.

2 Full Test.

A FULL TEST shall be carried out following installation and after alterations (e.g. relaying, ballast cleaning or insulation changing, renewed/ repaired apparatus, leads or jumpers) or changed settings.

2.1 Examine the track circuit (NR/SMS/TC14 Service A.)

Feed End

2.2 Measure the voltages and note the feed unit output strapping, as required on the paper or digital record card. Adjust as necessary.

Relay End

2.3 Measure the rail volts at the relay end rail terminations.

2.4 Measure the track relay coil voltage with the track circuit clear of trains and train shunt.

Final Check

2.5 Train Shunt test all extremities of the track circuit.

2.6 Drop Shunt test the track circuit.

The value of the drop shunt shall be noted, either as the track relay just makes its back contacts, or where only front contacts exist when they are fully open.

2.7 Check, by visual observation, that relay operation is sharp and positive.

Details of drop shunt values are in NR/SMS/Part/Z03

2.8 Record all test results on the paper or digital record card.

2.9 With the shunt box applied across the rails at the relay end, obtain the pickup shunt value.

2.10 Carry out a Maintenance Test.

Appendix A - Feed and Relay Units

1. **Colour Coding of Feed and Relay Units Feed End:**

Westinghouse original units - grey. Other - red.

Relay End:

- Yellow - BR938
- Blue - Shelf Type, 2.25Ω Red - NT1
- White - BR938, DC immune – for DC point heating

2. **Setting up a Quick Release Track Circuit for Testing**

At the track feed unit, adjust the input strapping to suit the 110Vac busbar voltage. Adjust the output strapping to match the length of the track circuit as given in the following table:

Length of Track (Approx) metres	Output Voltage	Strapping
1000	20	2 and 18
900	19	1 and 18
800	18	0 and 18

700	17	2 and 15
600	16	1 and 15
500	15	0 and 15
400	14	2 and 12
300	13	1 and 12
Below 300	12	0 and 12

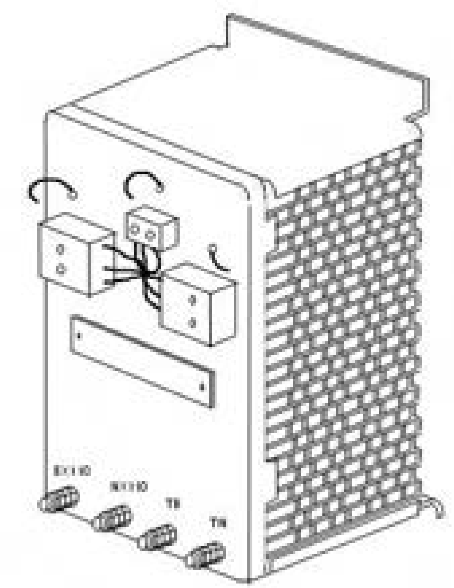

Figure 1: Input strapping and connections

End

Includes:	Reed Type RT Track Circuit equipment (Jointed and Jointless versions)
Excludes:	All other Track Circuit types

High voltages can be present on impedance bonds and other track circuit terminations. Switch off mobile phones if you are working in the proximity (3 meters) of the TX or RX equipment.

A double rail jointed reed track circuit shall never be re-configured as a single rail track circuit.

Due to operating problems, only the jointed configuration can be used in electrified areas. It may be configured as a single rail or a double rail track circuit.

Double rail track circuits require the use of impedance bonds.

More information on Reed Type RT track circuits can be found in NR/L2/SIG/11763

Layout Configurations

The Reed type RT track circuit is an audio frequency track circuit capable of operating in jointless and jointed modes. Both types use the same TX & RX but differ in the way the audio frequency signal is taken from the rails at the TX & RX.

The jointed configuration uses direct connections to the rails as in other TC types; the jointless version uses compound loops between the rails which inductively couple the audio frequency signal between the rails and TX/RX.

The Jointless version is always center fed (except where it adjoins a jointed section) the jointed version can be center fed or end fed.

Additional intermediate RXs can be positioned within both types (Jointed and Jointless) of a Reed TC, with a simple loop of cable mounted in the four foot.

The audio signal in the rails is detected by the simple loop and fed via an attenuator and the RX amplifier/filter to the TR which functions as at a jointed RX.

Track Circuits with Intermediate Receivers

Each of the two overlapping sections where a simple loop is fitted operates as an independent track circuit and shall be tested as such with record cards kept accordingly. Note that the TR will only be shunted by a train directly over the loop.

Centre Fed Track Circuits

Each half of a centre fed track circuit operates as an independent track circuit and shall be tested as such and record cards kept for each part.

Cut Section Track Circuits

Each cut section shall be treated as an individual track circuit and record cards kept accordingly.

Impedance Bond Tuning

Any impedance bond within the track circuit shall be tuned with the correct resonating capacitor across the auxiliary coil. Each tuning capacitor or module identifies the style of bond to which it should be fitted.

'Beating' Receiver Readings

If the receiver filter or dummy amplifier output or track relay voltage readings are seen to 'beat' (the measured voltage will rise and fall at a slow regular rate) interference between two track circuits of the same frequency is occurring. This shall be reported to your SM(S) immediately.

1. Maintenance Test Relay (Receiver) End

1.1 Connect a train shunt to the incoming track circuit terminations in the apparatus case and obtain a drop shunt value.

Where there is a variation in the shunt value from the last recorded (after making allowance for differing weather conditions) the drop shunt test shall be verified by a test carried out with the shunt applied to the rails.

Drop shunt values are in NR/SMS/PartZ/Z03 – Train Detection Reference Values.

1.2 Measure using a digital meter the AC voltage on the receiver track filter (RT7202, RT7212) between terminals 11 and 12.

- 150mV to 300mV

If an attenuator filter is fitted (RT7302) replace this with a dummy amplifier and Measure the output voltage.

- 75mV approx.

If the voltages are incorrect investigate the cause. If the resistor tapings are adjusted the FULL TEST shall be carried out.

1.3 With the track circuit clear of trains and train shunts, Measure the voltage across the track relay coils R1(+) and R4(-).

- Between 11.5V and 13.5V.

This indicates the correct functioning of the receiver.

1.4 Check that the surge arrestor is not hot to the touch. If it is hot check the track circuit adjustments and connections.

1.5 Assess the condition of ballast/ ground conditions.

1.6 Compare results with previous records for significant variation.

A variation in drop shunt value may be caused by variations in the equipment or environment. In wet conditions, a low value of drop shunt can be expected. In dry or icy conditions, a higher value will be obtained.

If the drop shunt exceeds the highest value for the track circuit, look for degraded ballast or debris.

If the drop shunt is lower than the minimum value, the track circuit shall be regarded as failed.

2. Full Test

The full test shall be carried out whenever alterations are made including; relaying, lead/ jumper renewal, equipment replacement, adjustment etc).

2.1 Examine the track circuit in accordance with NRSMS/PartC/TC06 – Track Circuits: Reed - Service A.

2.2 Check the impedance bond (where fitted and where accessible and without removing) for the following:

a) • Correct glands fitted.

b) • Drain holes clear (on Howells & WH3 bonds).

c) • Terminal box connections.

d) • Tuning capacitor.

2.3 Check that the impedance bonds are tuned with the correct resonating circuit across the auxiliary coil.

2.4 With a suitable meter connected across the rails, check that when the resonating circuit is disconnected the rail voltage falls, and when it is re- connected the rail voltage rises.

2.5 Measure the voltage across the resonating circuit; Check that it is in the correct ratio with the rail-to-rail voltage (Appendix A). If not, the impedance bond shall be investigated for a fault.

2.6 Check that all the rail connections and bonding are secure.

If tightened is required, it shall be to the torque detailed in NR/SMS/PartZ/Z03 – Train Detection Reference Values.

Feed (Transmitter) End

2.7 Measure the primary AC voltage of the constant voltage transformer (NT1202) between terminals BX110 and NX110.

- 99V to 121V.

2.8 Measure the supply to the power amplifier between terminals T5 and T6.

- 14V to 16V.

2.9 Measure the DC input voltage of the oscillator amplifier (RT5001) between terminals A1(+) and A2(-):

- 15V to 17V.

2.10 Disconnect a track feed link and connect a suitable meter (capable of measuring AC current to at least 2A) on the AC current range across the link.

a) Apply a short circuit across the rails at the feed end connections and Measure the current (Appendix B).

b) Remove the short circuit and observe that the current reading falls.

c) The current fall should be less than 150mA.

d) Remove the meter and restore the link.

e) Be aware that high back E.M.F. may develop across the link terminals when the link is disconnected.

f) The link terminals shall not be shorted together to discharge the E.M.F. this shall be done using a resistor of approximately 250kΩ or a meter with an equivalent internal resistance.

g) Do not short circuit the output of the power amplifier as this could result in serious damage to the equipment.

Relay (Receiver) End

2.11 Measure the input AC voltage of the power supply unit (RR9121).

- 99V to 121V.

2.12 Measure the DC supply voltage at the receiver amplifier (RR2002) between terminals D2(+) & A3(-)

- 12V to 13.8V.

2.13 Measure using a digital meter the AC voltage on the receiver track filter (RT7202, RT7212) between terminals 11 and 12.

- 150mV to 300mV.

2.14 If any of the values obtained in 2.13 are out of range, the receiver track filter (RT7202, RT7212) shall be adjusted by changing the tapings on terminals 21, 22, and 23.

Before any adjustments are made consideration should be given to the condition of the track causing low ballast resistance or any factors.

2.15 If after adjustments have been made in 2.14 and voltages in 2.13 are still out of range, the feed end track filter (RT7202, RT7212) shall be adjusted on terminals 21, 22 and 23.

When adjustments have been made in 2.13 and 2.14 it is necessary to re-start the FULL TEST at 2.9.

2.16 With the track circuit clear of trains and train shunts Measure the voltage across the track relay coils R1(+) and R4(-)

- Between 11.5V and 13.5V.

Compound Loops (Jointless configurations only)

2.17 Check that the loop is undamaged and securely fitted in the four foot. Check that the connections between the loop and the track filter / surge divider are undamaged and secure.

Intermediate Receivers with Simple Loops (Jointed/Jointless configurations where provided)

2.18 Check that the loop is undamaged and securely fitted in the four foot. Check that the connections between the loop and the attenuator filter are undamaged and secure.

2.19 Measure the input AC voltage of the power supply unit (RR9121).

- 99V to 121V.

2.20 Measure the DC supply voltage at the receiver amplifier (RR2002) between terminals D2(+) & A3(-)

- 12V to 13.8V.

2.21 Replace the attenuator filter (RT7302) with a dummy amplifier and Measure the AC output voltage with a suitable digital meter:

- 75mV approx.

2.22 If any of the values obtained in 2.21 are out of range, the attenuator filter (RT7302) it shall be adjusted by using its variable resistor settings.

Before any adjustments are made consideration should be given to the condition of the track causing low ballast resistance.

2.23 If after adjustments have been made in 2.22 and voltages in 2.21 are still out of range, the feed end track filter (RT7202, RT7212) shall be adjusted on terminals 21, 22 and 23.

When adjustments have been made in 2.21 and 2.22 it is necessary to re-start the FULL TEST at 2.9.

2.24 With the track circuit clear of trains and train shunts Measure the voltage across the track relay coils R1(+) and R4(-)

- Between 11.5V and 13.5V.

Final Checks

2.25 With the train shunt set to 0.5Ω, (0.3Ω if impedance bonds are fitted) drop shunt all extremities of the track circuit.

2.26 With the train shunt applied across the rails, obtain a drop shunt and a pick-up shunt value.

Drop shunt values are in NR/SMS/PartZ/Z03 – Train Detection Reference Values.

2.27 Assess the condition of ballast/ ground conditions and Record all details along with any new settings on the paper or digital record card.

Interference Test

2.28 Remove the BX110 fuse to the TX and Check that the track relay drops. Measure the AC voltage on the TX track filter.

If a reading greater than 8mV is obtained, replace the RX amplifier with a dummy amplifier and Measure the output of this. If a reading greater than 8mV is still found, inform your SM(S) immediately.

Fault Finding Guidelines

Full fault-finding guidelines can be found in NR/L2/SIG/11763.

APPENDIX A - Impedance Bond Voltage Ratios

Impedance Bond Style	Voltage Ratio
DE	40:1
MR	56:1
P3	45:1
S	56:1
WH3	56:1

APPENDIX B - Transmitter Power Amplifier Currents

TC Type	Amplifier Type	Terminals	AC Current	
			Min	Max
Double Rail	RT7101	1 and 2	1.2A	1.8A
	RT7112	10 and 12		
Single Rail	RT7111	1 and 2	1.1A	1.4A
	RT7112	11 and 12		

APPENDIX C - Transmitter Power Amplifier Voltages

TC Type	Amplifier Type	Terminals	AC Voltage (Approx.)
Double Rail	RT7101	1 and 2	17V
	RT7112	10 and 12	
Single Rail	RT7111	1 and 2	13V
	RT7112	11 and 12	

END

Includes:	AC Rectified (Diode) Track Circuit equipment
Excludes:	All other Track Circuit types

Carry out the following tests and record the results on the paper or digital record card.

1. Maintenance Test – Feed / Relay (Near) End

1.1 Note and record the strapping of the feed resistor.

1.2 Measure and record the AC voltage across the feed resistor.

1.3 Measure and record the AC and DC voltage at the relay coils and across the rails.

1.4 Connect a shunt box across the track circuit links and measure the drop away and pick up shunt.

Drop shunt values are in NR/SMS/Part/Z03.

1.5 Compare the results with previous records for significant variation.

1.6 If any adjustment is required then the FULL TEST shall be carried out.

2. Full Test

The full test shall be carried out whenever alterations are made including; relaying, lead/ jumper renewal, equipment replacement, adjustment etc).

Feed/Relay End (Near)

2.1 Note and record the strapping of the feed resistor.

2.2 Measure and record the AC voltage across the feed resistor.

2.3 Measure and record the AC and DC voltage at the relay coils and across the rails.

2.4 Connect a shunt box across the track circuit links and measure the drop away and pick up shunt.

Diode End (Remote)

2.5 Measure and record the AC and DC voltage across the rails.

2.6 Disconnect one side of the diode and Measure the AC and DC current between the disconnected side of the diode and its termination, reconnect the diode.

2.7 Connect a shunt box across the rails and measure the drop away and pick up shunt.

If adjustments are required to the track circuit to bring the drop shunt to a satisfactory level, the full test shall be carried out again.

Appendix A - Strapping Matrix for Feed Resistor Adjustment

The drop shunt can be varied by adjusting the resistor strapping. Increasing the resistance will lower the voltage and increase the drop shunt, conversely decreasing the resistance will increase the voltage and decrease the drop shunt.

Feed Resistance	Input to	Output to	Strap 1	Strap 2	Strap 3	Strap 4
33Ω	T11	T12	T13 to T15	T15 to T17		
22Ω	T11	T12	T13 to T15	T14 to T16		
13.2Ω	T11	T12	T13 to T15	T15 to T14	T11 to T16	
11Ω	T11	T13	T13 to T14			
8.8Ω	T11	T12	T13 to T15	T14 to T02	T16 to T01	
7.3Ω	T11	T13	T01 to T02	T14 to T15	T15 to T13	
5.5Ω	T11	T13	T01 to T02	T13 to T16	T16 to T15	T15 to T14

End

Includes:	FS 2600 Type Track Circuit equipment
Excludes:	All other Track Circuit types

GENERAL

The FS2600 shall never be configured as a single rail track circuit.

High voltages can be present on impedance bonds and other track circuit terminations.

Test Equipment

Only a high impedance digital voltmeter (DVM) like the Fluke 23, Megger M2006 (or equivalent) shall be used for all readings.

A special test lead is required to connect the meter to the receiver unit monitor point socket.

A manufacturer's set up box is required for the receiver sensitivity set up.

A universal track circuit shunt box shall be used for all drop shunt tests.

Impedance Bonds

Howells or Westinghouse Mk3 type bonds require a 5mm drain hole in the bottom of the termination box to prevent water accumulation.

Impedance Bond Tuning Capacitors

Check the tuning capacitor is mounted as close as possible to the terminal block to reduce failures caused by vibration induced flexing.

Alternatively, the capacitor can be mounted on the wall of the terminal box and connected to the terminals by means of a fly lead made of fine multi-stranded wire soldered to the capacitor and connected to the terminal block by crimp connectors.

Equipment Disconnection

Check that the TX end fuse is removed before making any alterations or connections to the TX end impedance bond. Before removing the TX or RX remove the power supply and track fuses.

After changing an RX unit, the receiver sensitivity procedure shall be carried out. It is however permissible to delay this for up to 24 hours by re-using the configuration plug from the old unit providing a satisfactory drop shunt test has been carried out.

Configuration Plug

It has been found that in some instances internal wires in the configuration plug can become trapped by the cover leading to internal shorting and incorrect operation of the track circuit. When changing the plug always check that no wires have become trapped by the cover.

Carry out the following tests and record the results on the paper / digital record card

1. Maintenance Test Feed

Transmitter End

1.1 Check the security and the fixing of the TX equipment.

Transmitter and Intermediate Impedance Bond (Where Fitted)

1.2 Check the impedance bond for the following:

a) Correct glands fitted.

b) Drain holes clear (on Howells & WH3 bonds).

c) Terminal box connections.

d) Tuning capacitor connecting leads for cracks or fractures.

1.3 Check that all the rail connections and bonding are secure.

If tightened is required, it shall be to the torque detailed in NR/SMS/PartZ/Z03 (Train Detection – Reference Values).

Relay (Receiver) End

1.4 Check the security and the fixing of the RX equipment.

1.5 Observe the RX unit LEDs are giving the correct ‘track clear’ indications (Appendix A).

1.6 Remove the RX unit monitor point socket protective cover and connect the DVM to the socket using the special test lead. Measure the track clear monitor point voltage.

1.7 Connect the track shunt box across the rails at the intermediate impedance bond or if at the end of track circuit section connect it at the RX unit.

1.8 Set the shunt box to 0.6Ω and depress the button.

1.9 Observe the LEDs are giving the correct track shunted indications (Appendix A).

LEDs Input-A Valid and Input-B Valid might not change states simultaneously when the track is shunted, a momentary delay might be observed.

1.10 Measure the track shunted monitor point voltage then release the shunt button.

1.11 Compare the results with previous records obtained under similar conditions. If the results are not similar the cause shall be investigated and rectified. A FULL TEST shall then be carried out.

1.12 Disconnect the track shunt box and the DVM from the RX monitor point socket.

1.13 Check that the protective cover is refitted to the RX monitor point socket.

1.14 Check the impedance bond for the following:

a) Correct glands fitted.

b) Drain holes clear (on Howells & WH3 bonds).

c) Terminal box connections.

d) Tuning capacitor connecting leads for cracks or fractures.

1.15 Check that all the rail connections and bonding are secure.

If tightened is required, it shall be to the torque detailed in NR/SMS/PartZ/Z03 (Train Detection – Reference Values).

1.16 Record the ballast and weather conditions on the paper / digital record card.

2. Full Test

The full test shall be carried out whenever alterations are made including relaying, lead/jumper renewal, equipment replacement, adjustments etc.

2.1 Examine the track circuit in accordance with NR/SMS/PartC/TC09 (Track Circuits:FS2600) - Service A.

<u>Feed (Transmitter) End</u>

2.2 Examine the TX unit case, connectors, terminations and plug couplers.

2.3 Check the connections, wiring and terminations (as applicable) and ventilation grills. Check that they are not blocked.

2.4 Measure the supply voltage between terminals 14 and 15:

a) 99V to 121V AC.

2.5 Check that the TX voltage adjustment tap is set to 115V (terminal 11 linked to terminal 8).

2.6 Measure using a DVM the voltage on the TX output terminals and the voltage across the rails. Check they are within the limits shown in the Table 1:

TC Type	TX O/P Terminal	O/P Voltage	Rail Voltage
Without Intermediate	3 and 4	80V to 120V AC	5V to 11V AC
With Intermediate Bond	5 and 6	160V to 240V AC	6V to 15V AC

Table 1

Transmitter End Impedance Bond (Where Fitted)

2.7 Remove the TX end track fuse and apply a short circuit across the tuning capacitor then refit the TX end track fuse.

2.8 Measure the voltage across the auxiliary coil. Check that this is less than the voltage across the cables from the TX, if it is not, reverse the phasing of the impedance bond.

2.9 Measure the TX rail voltage, then remove the TX end track fuse, and remove the short circuit across the tuning capacitor. Refit the TX end track fuse.

2.10 Measure the rail voltage, check it has increased with the short removed from the tuning capacitor and is within the limits as follows:

a) No Intermediate Bond 5V to 11V AC.

b) Intermediate Bond Fitted 6V to 15V AC.

Intermediate Impedance Bond (Where Fitted)

2.11 Measure the rail voltage:

a) Minimum of 3V.

2.12 Measure the voltage across the auxiliary coil; Check this voltage when the bond is resonated is in the ratio of 1:56 to the rail voltage.

If it is not the impedance bond shall be investigated for a fault.

2.13 Measure the rail voltage then apply a short circuit across the tuning capacitor, check the voltage falls then remove the short circuit.

2.14 Disconnect the tuning capacitor, check the rail voltage falls. Reconnect the tuning capacitor.

Relay (Receiver) End

2.15 Examine the RX unit case, check the connections, wiring and terminations (as applicable).

2.16 Check the ventilation grilles are not blocked.

2.17 Observe the RX unit LED's are giving the correct 'track clear' indications (Appendix A).

2.18 Measure the supply voltage:

a) 99V to 121V AC.

2.19 Remove the RX unit monitor point socket protective cover and connect the DVM to the socket using the special test lead. Measure the track clear monitor point voltage.

2.20 Connect the track shunt box across the rails at the intermediate impedance bond or if at the end of track circuit section connect it at the RX unit.

2.21 Drop shunt the track circuit, measure the shunt when both RX relays are de-energised.

Drop shunt values are in NR/SMS/PartZ/Z03 (Train Detection – Reference Values).

2.22 Observe the operation or the relays through the RX window. Check both relays drop when both Valid LEDs are extinguished.

2.23 Observe the LEDs are giving the correct track shunted indications (Appendix A).

2.24 LEDs Input-A Valid and Input-B Valid might not change states simultaneously when the track is shunted, a momentary delay might be observed.

2.25 Measure the track shunted monitor point voltage.

The Input-A Valid and Input-B Valid LEDs might not extinguish at the same monitor point voltage. However, the higher reading must not exceed the lower reading by 10%.

2.26 If a satisfactory drop shunt cannot be obtained the cause shall be investigated and rectified, a FULL TEST shall be carried out again.

Receiver End Impedance Bond (Where Fitted)

2.27 Measure the rail voltage:

a) Minimum of 3V.

2.28 Remove the RX end track fuse and apply a short circuit across the rails, apply a short circuit across the tuning capacitor then remove the short circuit from across the rails.

2.29 Measure the rail voltage and check it has fallen from the value obtained in 2.27. Remove the short circuit across the tuning capacitor.

3. Final Checks

3.1 Train shunt all extremities of the track circuit.

3.2 Check that the protective cover is refitted to the RX monitor point socket after the DVM is removed.

3.3 Record the ballast and weather conditions on the track circuit record card.

4. Receiver Sensitivity Set Up Procedure

These tests shall be carried out if a receiver unit has been replaced. The set-up box is to be used.

4.1 Connect a shunt box across the rails at the intermediate bond (if fitted) otherwise at the RX end. Check by use of a DVM the rail voltage disappears when 0Ω is applied via the shunt box button.

4.2 Remove the RX track fuse.

This is to check that the RX unit is not damaged when the set-up plug or configuration plug are removed.

4.3 Connect a DVM switched to AC to SK1 and SK2 on the set-up box, set the MIN/MAX control to ‘MAX’, set the COARSE and MEDIUM switches to position 4, set the FINE switch to position 1 and set the ‘LINK’ switch to ‘SET UP’.

4.4 Fit a blank configuration plug shell to the 15-way D type connecter on the set-up box.

4.5 Check for correct alignment and fit.

4.6 Connect the 25-way connector loom to the set-up box and the other ends to the 9-way and 15-way connectors on the RX unit. Re-fit the track fuse.

4.7 Look up the Channel Specific Value for the channel number in NR/SMS/PartZ/Z03 (Train Detection – Reference Values).

Check that account is taken of any intermediate bond.

4.8 Press the set-up button and adjust the MIN/MAX control until the reading on the DVM matches the Channel Specific Value. Lock the MIN/MAX control and release the set-up button.

4.9 Set the shunt box to 4Ω. Press the button on the shunt box and the set-up button on the set-up box. Measure the voltage on the DVM and record it as 'ratio'. Release the buttons on both boxes.

4.10 Look up the MPV set up 'step increase' in Appendix B for the channel number and locate the 'ratio' in Appendix C. Move up the table the number of rows of the 'step increase' value and record the target MPV set up value.

4.11 Adjust the 'COARSE', 'MEDIUM' and 'FINE' switches in turn to get the reading on the DVM as close as possible to the target value and within the upper and lower limits.

4.12 Set the 'LINK' switch from 'SET UP' to 'LINK A', if the 'NO LINK' LED is lit go to 4.14. If it is not lit go to 4.13.

Note which LEDs on the set-up box are lit and connect one of the wire links provided with the configuration plug between the pins on the configuration plug corresponding to the lit LEDs on the set-up box.

4.13 If the lit LEDs do not extinguish or if other LEDs light check the link for correct fitment.

4.14 Set the 'LINK' switch in turn to 'LINK B, LINK C' and 'LINK D' Repeat 4.13 if any of the LED's (except the 'NO LINK' LED) light.

4.15 Turn the switch back from 'LINK D' to 'LINK A' ensuring that the LEDs around the configuration plug remain extinguished (except the 'NO LINK' LED).

4.16 If any light, remove all the links using the provided extractor tool and start again at 4.12.

4.17 Remove the configuration plug from the set-up box and check each pin and wire for the links are pushed firmly home into the connector hole. Check each is fully home by gently pulling on the wire.

4.18 Fit the hood to the configuration plug and write the link settings and name of the track circuit on the labels provided affixing these to the hood.

4.19 Remove the RX track fuse. Remove the 15-way D type plug from the RX leaving the 9-way connector in place. Fit the configuration plug to the RX 'SET UP' socket.

Do not over tighten the securing screws.

4.20 Re-fit the RX track fuse and check that the DVM is still indicating a value between the upper and lower limits of the MPV set up. If not start the Receiver Sensitivity Procedure again from 4.1.

4.21 With the shunt box still connected, set it to 0.6Ω and press the button. Measure the monitor point voltage.

4.22 Record the target and actual MPV set up link settings, weather and ballast conditions on the front of the track record card. Compare the new reading with the previous readings reporting any differences to your SM(S).

4.23 Observe that the LEDs in the RX unit are indicating that the track is shunted (Appendix A).

4.24 If the LEDs do not indicate that the track circuit that is shunted with the 0.6Ω drop shunt look for a fault with the track circuit or an error in the set-up process and then repeat the FULL TEST.

4.25 If this does not remedy the low drop shunt it can be improved by adjusting the 'COASE', 'MEDIUM' and 'FINE' switches to lower the MPV (to a minimum of 2.2v). You shall inform your SM(S).

Never increase the gain.

4.26 Remove the 9-way D type connector from the RX 'MONITOR POINT' and check that the protective cover is correctly fitted.

4.27 Drop shunt the track circuit, measure the shunt when both RX relays are de-energised.

Drop shunt details are in NR/SMS/PartZ/Z03 (Train Detection – Reference Values).

4.28 Observe the operation or the relays through the RX window. Check that both relays drop when both Valid LEDs are extinguished.

4.29 With the train shunt still applied obtain a pickup shunt value.

4.30 Repeat 4.28 and 4.29 with the train shunt applied to the incoming track circuit cable terminations in the apparatus case/equipment room.

4.31 Record all the obtained values and details with the latest setting number from the front of the record card and the reverse of the card.

Appendix A - Receiver Unit LED Indications

LED	Track Clear	Track Shunted
Supply	On	On
µP A Running	Flashing	Flashing
Input-A Valid	On	Off
µP B Running	Flashing	Flashing
Input-B Valid	On	Off
Output	On	Off

Table 4

END

Includes:	All single and double rail 50Hz track circuits, VT1(SP) types
Excludes:	All other Track Circuit types

High voltages might be present on the terminals of capacitors in circuit at the feed or relay end of a track circuit, on impedance bonds and other track circuit terminals.

Always use an insulated spanner to turn the nuts of links connecting fixed or adjustable capacitors.

Links shall be held by their insulated knobs.

Capacitors disconnected from a circuit shall be discharged for safety by temporarily applying a short circuit to them (NR/SMS/PartC/TC00 (Track Circuits General) contains details of how to discharge a capacitor).

Damaged or disconnected red bonds, shall be reported to E.C.O. and the required actions taken.

A faulting guide and adjustment details for this type of track circuit can be found in NR/SMTH/Part10/FF07 (Faulting Guide: 50Hz AC Track Circuits).

Cut Section Track Circuits:

Each cut section shall be treated as an individual track circuit and record cards kept accordingly.

Bonding:

Damaged or disconnected bonds (other than red bonds, see ‘warning’), shall be investigated and actioned.

Before bonding is connected, all contact surfaces shall be wire brushed and a thin film of electrolytic paste applied.

Bonds across rail joints shall be of a low resistance as this can influence the characteristics of the track circuit.

Over Resonance (See Also Special Stagger Test)

Over resonance of impedance bond track circuits, or ‘Spanish Condition’, occurs when setting the relay end capacitor to over resonate combines with the inductance of the track to create a circuit that can resonate with applied 50Hz interference even when the track feed is shunted.

The usual cause is a high relay end capacitance (associated with an incorrectly phased relay end bond) and a failed IRJ. To prevent this, relay end capacitor settings above 9μF shall be avoided where possible or the Special Stagger Test carried out.

Layout Configurations

Where a short double rail track circuit (100m or less) with impedance bonds is required, the design normally employs a single rail feed transformer in reverse mode, with its low voltage winding feeding the track.

VT1(SP) Track Circuits:

The VT1(SP) track circuit has been designed to replace standard single rail 50Hz AC track circuits in limited situations where certain electric traction units have been authorised to run (e.g. class 373 trains).

The VT1(SP) track circuit uses the same principle of operation as the standard 50Hz type but has a delay unit attached to its adapted VT1 type relay by an interconnecting cable.

In this configuration, the clearing of the track circuit after removal of the train shunt is delayed by at least 2 seconds.

The VT1(SP) unit is also distinguished from the standard VT1 by having a revised small label at the bottom of its plug board and a large label at the top of its plug board.

The feed transformer is wired such that the primary and secondary windings are interchanged so as to achieve an output of 85V - 90V. A label shall be attached to the transformer to inform personnel that the primary and secondary connections have been wired in this way.

A 30μF - 60μF variable capacitor is used instead of the standard 20μF type at the feed end to increase current flow and rail voltage.

A 21Ω 15W variable resistor is added at the relay end to de-sensitise the relay end circuit and reduce the relay voltage to 1.5V +/- 0.5V.

A label should be attached to the resistor warning personnel not to change it or its adjustment setting.

Traction Spikes at Relay End

Double Rail Track Circuits:

This can be prevented by fitment of a transient suppressor unit with the permission of the Route Asset Manager (S&T).

Single Rail Track Circuits:

This can be prevented by fitment of an isolating transformer with the permission of the Route Asset Manager (Signals).

Installing Insulated Rail Joints: (IRJs)

When an IRJ is renewed, it shall be cleaned of any swarf and fully tested at the time of installation.

Check good electrical contact by scraping off rust down to bright metal before attaching test probes.

Glued IRJ's shall be tested with a 500V insulation tester before they are welded into place.

SGE AB711 Style Relay

There is a known failure mode with this type of track circuit, where the vane cuts a groove into the stop allowing it to become jammed. This can lead to a Wrong Side Failure, where the track circuit shows clear whilst occupied.

A workshop Instruction was issued to resolve the failure mode in 1962, but some of the unmodified relays are still in operational use.

When carrying out maintenance and an unmodified AB711 relay is found, report it to your SM(S).

1. Maintenance Test

Control Voltage, Phase Angle, and Stagger Tests

1.1 Measure the voltage across the control coil with the track circuit clear of trains and train shunt. Compare the results with the previous results.

The phase and stagger tests assume the use of the MK 4 direct reading phase angle meter (cat. no. 40/56014), if other test instruments are to be used for these, consult the relevant documentation since complex calculations can be required.

1.2 Connect the 'Local' and 'Control' as shown in Table 1 .

	Local BX		**Control BX**	
Relay	**Red Lead**	**Black Lead**	**Red Lead**	**Black Lead**
VT1 &VT1(SP)	7 or 1	8 or 2	5	6
G2/G4	Q1	Q2	R1	R2
CE391	Q1 or 7	Q2 or 8	R1 or 5	R2 or 6
AB401/AB402	Q1	Q2	R1	R2
L4	Q1	Q2	R1	R2
AB711	Q1	Q2	R1	R2

Table 1 - Phase Angle Measurement

1.3 Measure the phase angle with the switch in the “Phase Angle” position (Appendix A).

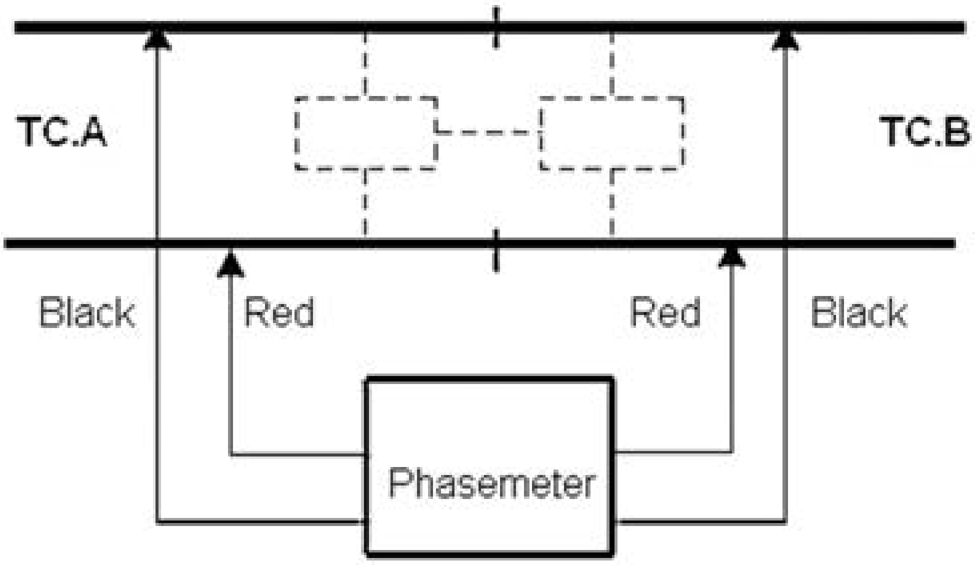
The ideal readings are, with the phase angle between 55º and 85º and the phase voltage 25% above the normal operating voltage given on the relay label.

1.4 Connect the meter as shown below and set the switch to “stagger”.

For the correct stagger the Mk4 meter needle shall be in the green sector with both green lights alight.

The needle just reaches the green sector (100º - 110º) for stagger between a double and single rail track circuit.

The needle should be well into the green sector (160º - 180º) for the stagger between two double rail track circuits.



To conserve the internal batteries, switch to PHASE (OFF) when readings are not being taken.

Drop Shunt Test

1.5 At the relay end of the track circuit, connect the train shunt box across the rails and drop shunt the track circuit.

Drop shunt values can be found in NR/SMS/PartZ/Z03 (Train Detection - Reference Values).

If a satisfactory drop shunt value is not obtained, fully check and re-test the track circuit according to the Full Test procedure (entering comment in the “Remarks” section of the record card).

Single Rail Track Circuits Only:

1.6 With the train shunt set to 0.5Ω apply the shunt across the rails at all 'stub end' extremities of the track circuit.

If the train shunt does not drop the relay, the bonding shall be investigated.

1.7 Assess the condition of the ballast.

Record all test results on the paper or digital record card. Compare the results with the previous results.

Significant changes in the drop away shunt value shall be investigated. (Any changed weather conditions that could affect the ballast resistance shall be taken into account).

2. Full Test

On installation and after alterations, e.g. relaying, ballast cleaning or insulation changing has taken place, apparatus has been changed, leads or jumpers have been renewed/repaired or settings have been changed, a Full Test shall be carried out. These tests assume the track circuit is not occupied by a train unless otherwise stated.

2.1 Examine in accordance with NR/SMS/PartC/TC08 (Track Circuits: AC 50Hz) Service A.

2.2 With the train shunt set to 0.5Ω, apply the shunt across the rails at all the extremities of the track circuit. Check that the track relay drops sharply.

3. Feed End

3.1 Measure the following voltages, adjusting as necessary.

a) Power supply - Acceptable value is 99V - 121V.

b) Across the feed links. Single Rail TCs.

c) Across Surge Arrester. Double Rail TCs.

d) Across the rails.

e) The capacitor and note the capacitor setting.

3.2 Measure the current to the track. Between 0.4A and 0.8A for standard type and between 0.4A and 1.4A for VT1(SP).

3.3 If applicable, carry out Feed End Impedance Bonds steps.

4. Relay End

4.1 Measure the following voltages, adjusting as necessary.

a) Across the rails.

b) Across the feed links. Single Rail TCs.

c) Across Surge Arrester. Double Rail TCs.

d) The track relay coil.

4.2 Measure the current from the track. Between 0.3A and 0.5A.

4.3 Record the approximate control resistor setting.

4.4 Measure the Control Voltage (Steps 1.1 and 1.2).

4.5 Measure the Phase Angle and carry out the Stagger Tests (Appendix A).

4.6 If applicable, carry out Relay End Impedance Bonds steps.

5. Local Policy Requirement

5.1 If applicable and only during a B service, Check the section of the NR/SMS/PartL/Index (Local Policies) for your area and carry out NR/SMS/PartB/Test/041 (Insulated Rail Joint Test) as directed.

6. Feed End and Relay End Impedance Bonds

6.1 Check that terminal B of the capacitor is connected via terminal E of the surge arrestor to the rail, and not to the bond coil.

6.2 Measure the voltage across the rails and the capacitor. Note the capacitor setting.

Calculate the voltage ratio and compare with the values given in the Impedance Bond Voltage Ratio Table, (Appendix C).

If necessary, carry out remedial action in accordance with the notes in Appendix C.

6.3 Measure the voltage across auxiliary coil and check that the bonds are phased correctly.

The voltage from/to the track shall be equal to or greater than the auxiliary coil voltage plus the voltage across the rails. If not, the auxiliary coil connections shall be reversed and the track retested.

If the feed end bond auxiliary coil is reversed, then the feed end transformer secondary connection shall also be reversed to maintain the correct stagger.

If the relay end bond auxiliary coil is reversed, then the track relay control coil connection shall also be reversed to maintain the correct operation of the track circuit.

6.4 If applicable, with trains running, check the traction imbalance in each section between bonds.

Take readings with peak hold current clamp meters on each side lead and observe the balance is within 5%.

6.5 Check that all the rail connections and bonding are secure. If tightening is required, it shall be to the torque detailed in NR/SMS/PartZ/Z03 (Train Detection - Reference Values).

7. Relay End Impedance Bonds

In addition to the steps 2.13 to 2.17 above carry out the following steps.

7.1 If the relay end capacitor is set at more than 9μF, check that an intermediate bond nearer to feed end (if fitted) is not set above 9.3μF.

7.2 Check the relay stability by increasing and decreasing the setting of the relay end capacitor by 1μF (or 0.323μF if provided), in turn.

Withdraw and replace the relay fuse at each alteration and check that the relay re-energises each time.

If it does not, then fully check and re-test the track circuit.

7.3 If a relay end bond capacitor is set at more than 10μF carry out the Special Stagger Test (Appendix A).

For settings above 12μF, inform your SM(S) before proceeding.

8. Intermediate Bonds

8.1 Measure the voltage across the rails and the capacitor. Note the capacitor setting.

Calculate the voltage ratio and compare with the values given in the Impedance Bond Voltage Ratio Table, (Appendix C).

If necessary, carry out remedial action as directed by the notes in Appendix C.

8.2 If applicable, with trains running, check the traction imbalance in each section between bonds.

Take readings with peak hold current clamp meters on each side lead and observe the balance is within 5%.

8.3 Check that all the rail connections and bonding are secure. If tightened is required, it shall be to the torque detailed in NR/SMS/PartZ/Z03 (Train Detection - Reference Values).

8.4 Check that the voltage between the apparatus housing metalwork and the following terminals is less than 10V AC.

a) Relay capacitor terminal B.

b) Relay control resistor.

c) Surge arrestor terminal E.

This check is to determine that the relay capacitor terminal B is connected to the surge arrestor terminal E and NOT to the impedance bond coil.

If the result is greater than 10V AC then the wiring to the rails shall be reversed as follows:

If the tail cable core numbering on the surge arrestor conforms to the wiring diagram, then reverse the tail cable cores at the impedance bond.

If the tail cable core numbering on the surge arrestor does not conform to the wiring diagram, then alter the cable cores at the surge arrestor to correspond with the diagrams.

Where two single cores are used, reverse them at the surge arrestor as this avoids going onto the track and opening up the bond terminal.

9. Final Checks

These tests shall be undertaken when satisfactory setting values have been obtained:

Drop shunt values are in NR/SMS/PartZ/Z03 (Train Detection - Reference Values).

9.1 With the shunt box connected across the rails at the relay end, obtain the Pick-Up shunt value.

It should be approximately 25% above the drop shunt figure.

9.2 Check the voltages across the track relay control and local coils are still satisfactory.

9.3 Re-secure any capacitor switch locking bars provided.

9.4 Record the values and other details on the paper or digital record card.

APPENDIX A - Stagger Test

To prevent the feed of one track circuit incorrectly energising the relay of an adjacent track circuit when an IRJ fails, it is essential that the rails of these adjacent track circuits are of opposite polarities.

This is called the 'stagger' of the track circuits.

For 50Hz AC track circuits, correct stagger is maintained by verifying that adjacent track circuits are 'out of phase' with each other.

Important Notes

a) Phase angle is directly related to the phase angle of the supply derived from the grid feeder point.

b) Where substation switching causes the supply to be fed from a different grid point, the phase angle of each track circuit supplied from that point can change phase by 180º. This might lead to un-staggered tracks, particularly at the boundaries of the affected supply area.

c) To prevent this, it is essential that the stagger of all affected track circuits is checked where the supply has changed its grid feeder point – advanced warning should be provided by the Electrical Control Room for that area.

d) At some boundary sites, a special supply is fed from the adjacent substation area to supply one or more track circuits with a supply of the same phase as their opposite ends.

e) This supply busbar should carry an identifying label, and in no circumstances shall track circuits supplied by one supply be switched to the other supply.

Phase Test

Connect the MK 4 direct reading phase meter at the relay terminals or plug board to avoid case wiring errors and any traction suppressors.

The meter gives a phase angle of between 0ºand 180º. The phase lead or lag is indicated by red lights.

APPENDIX B - Special Stagger Test

Carry out this test whenever a relay end bond capacitor needs to exceed 10μF so as to obtain satisfactory operation of the track circuit.

Do not adjust the relay end capacitor above 12μF without the permission of the Route Asset Manager (Signals).

Use a MK 4 direct reading phase angle meter.

1. Connect the ‘local’ and ‘control’ as shown in Maintenance Test step 1.1.

2. Short out one relay end IRJ and observe the behaviour of the track relay during passage of an electric powered train over the track circuit under test.

   NOTE: *Any phase change or voltage rise on the direct reading meter.*

   If there is a tendency of the relay vane to lift off its backstop during the passage of a train, accompanied by a large swing in phase angle and a rise in control voltage, proceed to step 4.

3. Remove the short circuit from across the IRJ.

Track Circuit Fails Special Stagger Test

4. Check that tests in the FULL TEST up to 2.21 are satisfactorily completed.

5. Check there is no residual voltage across relay coil with feed fuse removed.

6. Check that relay phase angle inverts by about 180ºfrom its ‘TC clear’ position when shunted by a train.

7. Check the voltage across the feed capacitor equals voltage across surge arrestor plus voltage across transformer secondary winding.

8. Check the voltage across the relay capacitor equals voltage across surge arrestor plus the voltage across relay control coil.

9. Check the feed current falls when track circuit is occupied.

10. Check the feed capacitor is not set to a higher value than relay capacitor.

11. If, after any defects have been rectified and all checks satisfactory, relay end capacitor still set at over 10μF consult your SM(S).

APPENDIX C - Impedance Bond Voltage Ratio Table

Impedance Bond Style	Voltage Ratio	Approx. DC Auxiliary Coil Resistance
WH3 (Howells)	56:1	3.3Ω
WH3 (WRSL)	56:1	3.0Ω
MR	56:1	3.4Ω
S	56:1	3.0Ω
P3	45:1	2.5Ω
DE	40:1	5.5Ω
M	42:1	4.0Ω (T0/T3)
M2/5	42:1	3.48Ω (T0/T3)
DD	42:1	5.5Ω
B	45:1	5.0Ω
B (Kent Coast only)	66:1	5.0Ω

Table 2 - Impedance Bond Voltage Ratio Table

The combination of G4 track relay and type 2 or type 3 impedance bonds shall be avoided.

If the ratio is more than 10% lower than the value stated above, the bond is faulty. If the bond is type WH3, MR or S the entire bond shall be replaced.

For other bonds the fault might be further isolated by checking the auxiliary coil resistance.

If this is correct the traction coil is defective, and the bond shall be replaced. The auxiliary coil might be replaced as an interim measure and re-tested.

On site replacement of the auxiliary coil cannot guarantee the precise tuning of the air gap, which requires workshop test equipment.

Arrangements shall be made to replace the bond at the earliest opportunity.

END

Includes:	Overlay Rail Circuit equipment
Excludes:	All other Rail/Track Circuit types

1. Maintenance test

1.1 Check that the rail circuit relay is de-energised.

Run In End

1.2 Apply a 0.5Ω shunt across the rails at the remote end of the rail circuit and check that the rail circuit relay energises.

1.3 Measure and record the relay voltage. The voltage should be less than the saturation voltage level of the relay, if not readjust as a corrective maintenance item.

1.4 Measure and record, using two train shunt boxes in series increase the resistance until the rail circuit relay de- energises.

1.5 Measure and record the relay voltage.

The voltage should be equal to or less than the relay drop away voltage.

Run Off End

1.6 Apply a 0.5Ω shunt across the rails at the remote end of the rail circuit and check that the rail circuit relay energises.

1.7 Measure and record the relay voltage. The voltage should be less than the saturation voltage level of the relay, if not readjust as a corrective maintenance item.

1.8 Measure and record, using two train shunt boxes in series increase the resistance until the rail circuit relay de- energises.

1.9 Measure and record the relay voltage.

1.10 Check that the rail circuit relay is de-energised at the end of the tests.

1.11 Record all test results on the paper or digital record card. (SMS Part R Test 261-Overlay Track)

End

Includes:	Single Frequency DC Coded Tracks (Used on the Western Route)
Excludes:	All other DC Coded Tracks

For information on this type of Track see SMS Appendix 12

1. Maintenance Test

Feed End

1.1 Using a digital volt meter with a Min/Max facility. Set the DVM to DC Min/Max and measure the DC voltage across the rails, allowing a few cycles to capture the positive and negative impulses.

1.2 Note the (+/-) values and record the results on the record card.

Relay End

1.3 Using a digital volt meter with a Min/Max facility. Set the DVM to DC Min/Max and measure the DC voltage across the rails, allowing a few cycles to capture the positive and negative impulses.

1.4 Note the (+/-) values and record the results on the record card.

1.5 Connect a train shunt across the track links. Obtain a drop shunt value.

It can be difficult to ascertain exactly at which point a CFR is de energised and energised.

As the train shunt value is reduced, the CFR "beat" will slow as the incoming 75 cycles per minute are interrupted/ distorted, and the voltage across the CFR R1/R2 connection diminishes.

The CFR will eventually slow to a point where its front contacts will fully open. The CFR may still be observed to still "pulse" slightly whilst resting on its back contacts, but as long as the front contacts remain broken, this can be accepted as a successful shunt.

1.6 Record the values on the paper / digital record card.

1.7 With the train shunt still connected across the track links, obtain the pick-up value.

The pick-up is achieved by increasing the shunt value until the back contacts break, the front contacts make and the CFR starts to beat. At first the pulse will seem irregular. Continue to increase the shunt until the distinctive and regular "beat" can be observed and heard. The front and back contacts should now be open for an equal amount of time.

1.8 Record the value on the record card and disconnect the shunt box.

1.9 If the drop shunt is lower than the minimum value shown in NR/SMS/Part Z/03, assess the ballast/ground conditions. Compare the results with previous records for any significant variations. Where there is a significant variation in values, retest the track. If there are still variations then a full test should be carried out.

A variation in drop shunt value may be caused by variations in the equipment or the environment. In wet conditions a higher drop shunt value can be expected. In dry or icy conditions, a lower value may be obtained. Poor ballast conditions can also affect the value of the drop shunt (see NR/SMS/TC00).

2. Full Test

A full test should be carried out whenever alterations are made including relaying, lead/jumper renewal, equipment replacement / adjustment etc.

2.1 Examine the track in accordance with NR/SMS/TC05 service A.

Feed End

2.2 Measure and record the feed end voltages, resistor settings, and other parameters as shown on the full test paper or digital record card

Relay End

2.3 Measure and record the feed end voltages, resistor settings, and other parameters as shown on the full test paper or digital record card (NR/SMS/T262/DC Coded)

2.4 Measure and record the Min/Max +/- DC voltage on the CFR coil.

2.5 Connect a train shunt across the track links. Obtain a drop shunt value and pick-up values.

2.6 If the drop shunt lower than the minimum value shown in NR/SMS/Part Z the track should be regarded as "failed" and the cause investigated.

2.7 With the track shunt set at 0.5 ohms, apply the shunt across the rails at the extremities of the track circuit. Check the CFR ceases oscillating.

2.8 Assess the condition of the ballast/ground.

2.9 Compare the results with previous records for any significant variations. Where there is a significant variation in values these should be investigated.

Due to the design of this DC Coded Track Circuit no residual voltage testing is required

End

Includes:	EBI Track 400 Audio Frequency Track Circuit
Excludes:	All other Track Circuits

1. Maintenance Test A1

Feed (Transmitter) End

1.1 Check all rail connections and bonding are tightened to the correct torque (Appendix K of NR/SMS/Appendix/10).

1.2 Check the display for a steady 'RUN' indication. If one of these indications cycles with the indication 'ERR' then refer to NR/SMS/Appendix/10 and investigate the reason for the error. An 'ERR' state shall not be left without authority from the SM (S).

Impedance Bonds (where fitted)

1.3 Check the impedance bond for the following:

a) Bond Covers correctly fitted and not damaged.

b) Drain holes clear (on Howells & WH3 bonds).

It is necessary to drill drain holes if they are not present. (Pre installation check).

c) Tuning capacitor or tuning module connections.

1.4 Check all rail connections and bonding are tightened to the correct torque (Appendix K of NR/SMS/Appendix/10).

Relay (Receiver) End

1.5 Check all rail connections and bonding are tightened to the correct torque (Appendix K of NR/SMS/Appendix/10).

1.6 Measure the rail-to-rail voltage at the EBI Track 400 equipment rail connections (Pole) using a TTM/MTM Vp, (See NR/SMS/Appendix/10 for additional information). For consistency this measurement shall always be carried out at the rails.

1.7 Measure the rail current in the rail within 1 metre and on the track circuit side of the rail connections with a Rocoil.
For a Single Rail track circuit the measurement shall be made in the Signal rail.

1.8 Where a tuned circuit is involved, Measure using a TTM/MTM the rail-to-rail voltage at the companion TU rail connection (Zero) at the frequency of the track circuit under test. (Vz).

The voltage measured in 1.6 (Vp Pole) divided by the voltage at the companion TU (Vz Zero) gives the Tuned Zone ratio (Tzr) where Tzr = Vp/Vz.

Check the ratio against the detail found in NR/SMS/Appendix/10. If the ratio is below specification, the low result usually relates to badly dressed cables and or poor connections, therefore, Check that the cables are dressed correctly and that all Tuning units' connection are correct, clean and tight.

1.9 Where a tuned circuit is involved, Repeat steps 1.6 to 1.8 for the adjacent/abutting track at this tuned zone – This track is 'under test' for the purposes of these steps.

1.10 Check the display for a steady 'PICK' or 'drop' indication. If one of these indications cycles with the indication 'ERR' then refer to NR/SMS/Appendix/10 and investigate the reason for the error. An 'ERR' state shall not be left without authority from the SM(S).

1.11 Record the Ith Threshold using the display on the receiver and compare this reading against the Record Card.
The Threshold value should be identical to previous recorded values. If it is not, the track has been set up without being noted on the record card and a Full Test shall be carried out.

1.12 Record the Inow AV current using the display on the receiver and compare this reading against the Record Card.
If the obtained reading is not within 10% of the Record Card, the reason for the discrepancy shall be investigated.

The RX current is the best measure of the track circuits' stability. Significant deviations from previous readings shall be investigated.

A significant deviation is indicated if the change of track current is greater than:

- ±20% OR
- ±10mA.

1.13 Record the ballast and weather conditions on the track circuit Record Card.

1.14 Using a shunt applied to the rails between the RX tuning unit rail connections obtain a drop shunt value and a pick up shunt value.

Shunt values are detailed in NR/SMS/Part/Z03.

On the pick-up shunt, allow 2 seconds between each value to allow the slow to pick relay drive from the RX to operate.

A Station Area frequency track will pick up in 1 second.

The pick-up value should normally be 0.1Ω higher than the drop shunt.

1.15 Compare the results with previous records (if available) obtained under similar conditions. If the results are not within ±10% the cause shall be investigated and rectified as appropriate. A FULL TEST shall then be carried out.

2. Full Test

2.1 Examine the track circuit in accordance with NR/SMS/TC17 service A.

Feed (Transmitter/OM) End

2.2 Examine the TX unit case, connector and terminations and check the plug coupler is pushed fully home.

2.3 Examine the TX unit frequency key and check it is fully turned to the right and latched into the key holder.

NOTE: Unlatching the key or removing it will cause the Relay to be de-energised and the track show occupied.

2.4 Examine the OM unit case, connector and terminations and check the plug coupler is pushed fully home.

2.5 Measure the voltage on the 110V signalling supply to the PSU.

2.6 Measure the voltage from the PSU to the Transmitter/OM (Vpsu). It should be in the range of 46VDC to 50VDC.

2.7 Measure the DC current drawn by the equipment.

- Open Line Frequencies, >250m long : 1.5A to 5A
- Open Line Frequencies, <250m long : 0.2A to 1.5A
- Station Area Frequencies, 1.5A to 5A

2.8 Measure the TX output voltage across terminals TM1 and TM2 using a TTM/MTM.

It should be in the range of 32V RMS to 34V RMS.

2.9 Record the OM Step Setting and Resistor Setting.

- OM Step setting is in the range from 1 to 27
- OM Resistor setting for Open Line frequencies –set at 0R
- OM Resistor setting for Station Area frequencies set at
  48R for TC feed<750m
  0R for TC feed>750m to 2km

2.10 Record the OM output voltage (Vout).

2.11 For Open Line frequency tracks - Measure the LMU(TU) I/P Voltage.

It should be in the range of 50V to 148V RMS.

2.12 For Open Line frequency tracks - Measure the TX TU/ETU I/P voltage on terminals 4 & 5 (Meter).

It should be in the range of:

0.6V to 2.0V RMS for track lengths 20m to 250m
0.5V to 15.0V RMS for track lengths 250m to 1100m

For Station Area frequency tracks - Measure the TX SATU/CU I/P voltage on terminals LINE 1 & 2 (Meter).
A value of 95V RMS shall not be exceeded.

2.13 Measure the rail-to-rail voltage at the EBI Track 400 equipment rail connections (Pole) using a TTM/MTM (Vp, See NR/SMS/Appendix/10).
For consistency this measurement shall always be carried out at the rails.

2.14 Measure the rail current in the rail within 1 metre and on the track circuit side of the rail connections with a Rocoil.
For a Single Rail track circuit the measurement shall be made in the Signal rail.

2.15 Where a tuned circuit is involved, Measure using a TTM/MTM the rail-to-rail voltage at the companion TU rail connection (Zero) at the frequency of the track circuit under test. (Vz).

The voltage measured in 2.13 (Vp Pole) divided by the voltage at the companion TU (Vz Zero) gives the Tuned Zone ratio (Tzr) where Tzr = Vp/Vz.

Check the ratio against the details found in NR/SMS/Appendix/10. If the ratio is below specification, Check that the cables are routed correctly and that all Tuning Unit connections are correct, clean and tight.

Impedance Bond and Track Capacitors (Where fitted)

The impedance of an impedance bond can be checked by measuring the EBI Track 400 voltage across the bond and the current through it. To take the current measurements use a Rocoil connected to a TTM.

2.16 Check all rail connections and bonding are tightened to the correct torque (See Appendix K of NR/SMS/Appendix/10)

2.17 Check the security and the fixing of the Track capacitor.

2.18 Measure using a TTM/MTM the rail-to-rail voltage.

Clauses 2.19 and 2.20 are not applicable to B3 3000 and B3 500 bonds

2.19 Measure the voltage across the auxiliary coil or tuning module, Check it is in the correct ratio with the rail-to-rail voltage (See NR/SMS/Appendix/10). If it is not the impedance bond shall be investigated for a fault.

2.20 Apply a short circuit across the tuning capacitor/module, Check that the rail voltage falls then remove the short circuit and Check the voltage rises.

Clauses 2.21 to 2.25 are applicable to Intermediate bonds only.

2.21 Place the Rocoil over the rail 1 metre before the Bond (TX side) and note the reading on the TTM (= amps, I1).

2.22 Repeat the measurement 1 metre from the bond on the RX side (I2)

2.23 Subtract I2 from I1 thus obtaining the current through the bond at the EBI Track 400 frequency.

2.24 Measure the rail to rail voltage (V) across the impedance bond.

2.25 Divide the voltage (V) by the current calculated from 2.23 thus giving the impedance (Z), Z= V / (I1-I2).

This value should be greater than 8Ω. If less than 8Ω, Check for traction imbalance before remedial action is taken with the impedance bond.

Relay (Receiver) End

2.26 Examine the RX unit case, connector and terminations and check the plug coupler is pushed fully home.

2.27 Examine the RX unit frequency key and check it is fully turned to the right and latched into the key holder.

Unlatching the key or removing it will cause the Relay to be de-energised and the track show occupied.

2.28 Measure the voltage on the 110V signalling supply to the PSU.

2.29 Measure the voltage from the PSU to the Receiver.

It should be in the range of 46VDC to 50VDC.

2.30 Measure the DC current drawn by the equipment.

- Relay Up : 100mA to 150mA DC

2.31 Check the display for a steady ‘PICK’ or ‘drop’ indication. If one of these indications cycles with the indication ‘ERR’ then refer to NR/SMS/Appendix/10 and investigate the reason for the error. An 'ERR' state shall not be left without authority from the SM (S).

2.32 For Open Line frequency tracks - Measure the RX TU/ETU O/P voltage on terminals 1 & 2 (Meter).

It should be in the range of 0.3V to 1.7V RMS.

For Station Area frequency tracks - Measure the RX SATU/CU O/P voltage on terminals LINE 1 & 2 (Meter).

2.33 Measure the rail-to-rail voltage at the EBI Track 400 equipment rail connections (Pole) using a TTM/MTM (Vp, See NR/SMS/Appendix/10).
For consistency this measurement shall always be carried out at the rails.

2.34 Measure the rail current in the rail within 1 metre and on the track circuit side of the rail connections with a Rocoil.
For a Single Rail track circuit the measurement shall be made in the Signal rail.

Low rail volts or rail current could be due to ballast or other track equipment, as well as a fault at the TX end of the track.

2.35 Where a tuned circuit is involved, Measure using a TTM/MTM the rail-to-rail voltage at the companion TU rail connection (Zero) at the frequency of the track circuit under test. (Vz).

The voltage measured in 2.33 (Vp Pole) divided by the voltage at the companion TU (Vz Zero) gives the Tuned Zone ratio (Tzr) where Tzr = Vp/Vz.

Check the ratio against the details found in NR/SMS/Appendix/10. If the ratio is below specification, the low result usually relates to badly dressed cables and or poor connections, therefore, Check that the cables are dressed correctly and that all Tuning units' connection are correct, clean and tight.

2.36 Record the Inow AV current using the display on the receiver and compare this reading against the Record Card.

If the obtained reading is not within 10% of the Record Card, the reason for the discrepancy shall be investigated.

If adjustment is required an auto-set routine shall be performed.

The RX current is the best measure of the track circuits' stability. Significant deviations from previous readings shall be investigated.

A significant deviation is indicated if the change of track current is greater than:

- ±20% OR
- ±10mA.

2.37 Record the Ith current value using the display on the receiver and compare this reading against the Record Card.

The reading should be identical to the Record Card.

If the readings are not identical, the track has been adjusted without recording the event. A new auto-set routine shall be performed.

2.38 Record the Inow ITOT current using the display on the receiver and compare this reading against the Record Card.

If the obtained reading is not within 10% of the Record Card, the reason for the discrepancy shall be investigated.

This is usually because there is an external noise sources creating undesired wideband interference.

2.39 Record the Inow QUAL value using the display on the receiver and compare this reading against the Record Card.

Anything less than 100% shall be investigated for poor signal transmission along the track circuit.

2.40 Measure the voltage across the energised track relay coils.

- 48V to 52V DC for the RX MOD 2 or later.

2.41 Using a train shunt applied to the rails between the RX tuning unit rail connections obtain a drop shunt value and a pick up shunt value.

Shunt values are detailed in NR/SMS/Part/Z03.

On the pick-up shunt allow 2 seconds between each value to allow the slow to pick receiver relay drive to operate.

A Station Area frequency track will pick up in 1 second.
The pick-up value should normally be 0.1Ω higher than the drop shunt.

2.42 Compare the results with previous records (if available) obtained under similar conditions. If the results are not similar the cause shall be investigated and rectified as appropriate. The FULL TEST shall then be repeated.

2.43 Record the ballast and weather conditions on the track circuit Record Card.

Interference Test (Crosstalk and Feedthrough)

This test checks the levels of in band and traction interference present at the RX, and requires temporary disconnection of the TX.

Check the fusing arrangements before this test as more than one track circuit can be affected.

2.44 Remove the B48 fuse or switch off the MCB to the TX and Check that the correct track relay drops. Record the Inow AV value from the receiver.

Open Line Double Rail tracks: The Inow AV reading shall be less than 8mA.

Open Line Single Rail tracks with 30m bonding: The Inow AV reading shall be less than 3mA.

Readings greater than these values shall be investigated.

Station Area tracks : The Inow AV reading shall be:

- less than 10% of 'Ith' OR
- less than 20mA

whichever is the lower.

A higher level shall be investigated (look for disconnected cable screens, TU failure, etc.) The track circuit shall be signed out of use and your SM (S) informed.

Extremity Tests

2.45 For Open Line frequency tracks - Apply a shunt, using the minimum shunt values, at the extremities of the track circuit, in accordance with the track plan, and Check the track relay drops for each application.

Minimum Shunt values are detailed in NR/SMS/Part/Z03.

For Station Area frequency tracks – Set a shunt box to 0.2Ω and carry out a shunt test at the following points in the track circuit:

- TX Pole, Mid Point, RX Pole
- At any other ends in Points tracks.

The track circuit should drop and record the RX current for each location with the Shunt in place.

Station Area Frequency Tuned Zone Impedance

2.46 For Station Area frequency tracks with Tuned Zones – Measure and Calculate the Tuned Zone Impedance at the TX and RX ends.

At the TX end calculate TZimp: $\mathrm{TZimp} = \left(\frac{\mathrm{CT}}{\mathrm{Ish}} - 1\right)$

Where: CT = Receiver input current (Inow AV) Measured when track is clear
Ish = Receiver input current (Inow AV) measured when a 1Ω shunt has been applied at the Tx end rail connections.

At the RX end calculate TZimp: $\mathrm{TZimp} = \left(\frac{\mathrm{CT}}{\mathrm{Ish}} - 1\right)$

Where: CT = Receiver input current (Inow AV) Measured when track is clear
Ish = Receiver input current (Inow AV) measured when a 1Ω shunt has been applied at the Rx end rail connections.

Repeat the RX end calculation for any other RX Tuned Zones in the track circuit.

TZimp shall be > 0.4Ω in all cases.

End

Includes:	Unistar HR
Excludes:	IBCL, RCPL and All Powered Point Machines and Mechanical points

GENERAL

Before the FPL test is carried out, a safe system of work shall be established so that a Signaller cannot set a route over or control the points being tested. See NR/SMS/PartA/A04 (Method Statement Summary).

To avoid injury whilst placing and removing gauges, it is recommended that you use the hands-free gauges (ask your SM(S)) or hold the gauges with pliers or mole grips.

Observe the Lock Prism indicators through the windows on the DLD (Drive, Locking, Detection) unit lid, only remove the lid of the DLD unit if the detection requires to be adjusted, or the windows are obscured (e.g. by dirt/moisture).

All adjustments shall be recorded as corrective maintenance.

Confirm detection by connecting a meter to the outgoing KR circuit with a final check in liaison with the Signaller that indications are visible at the signalling control centre.

Confirm that detection is made and broken by referring to the meter only.

1. FPL Test

These steps shall be undertaken for both normal and reverse positions of the points.

Use the 3.5mm point checking gauge and a 1.5mm gauge for this test.

1.1 Place the points on manual.

For the TOE Drive Lock and Detect Unit (DLD):

1.2 Place the 3.5mm gauge between the switch and stock rail at a point midway between the Drive and Detection Rods (this is where the two switch rail connection brackets meet).

1.3 Manually operate the points to the closed position and check that Lock Prism Indicators fail to align.

a) Check that detection is broken.

b) If the lock prism fails to complete its travel and engage, then this is a pass. Record the result on the record card and proceed to Step 1.4.

c) If the lock prism completes its travel, then this is a failure, and the drive rod end requires adjustment.

Additional gauges shall be added in 0.5mm increments until the lock prism fails to complete its travel. If the lock is still made at 5mm, this shall be recorded, reported to Integrated Control Centre (ICC), and investigated.

Carry out remedial action, the drive rod end shall now be adjusted to bring the points back to a position where they fail the 3.5mm test.

When the lock fails at 3.5mm proceed to step 1.4.

1.4 Place the 1.5mm gauge between the switch and stock rail at a point midway between the Drive and Detection Rods (this is where the two switch rail connection brackets meet).

a) Manually operate the points to the closed position and check that the Lock Prism Indicators align.

b) Check that detection is made.

c) If the Lock Prism Indicators align but detection is not made, then the test shall be treated as a fail.

Carry out remedial action, the detector rod end shall now be adjusted to bring them back to a position where they pass the 1.5mm test.

This action will require the main lid of the DLD to be removed to verify the detector bar markings – refer to Figure 1.

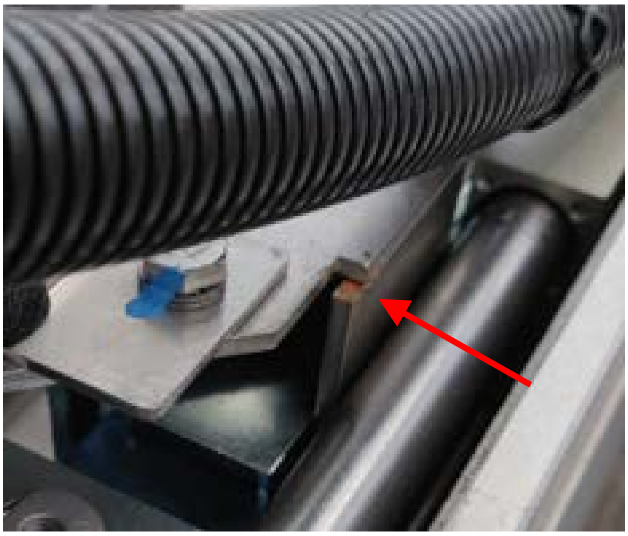


Figure 1 – Detector Bar Markings (indicated by arrow)

In wet or inclement weather the drying bags shall be removed and stored safely and the DLD body left open for the shortest possible time.

On completion of the work, any moisture shall be carefully removed, and the drying bags replaced before the lid is replaced.

When detection is made at 1.5mm you can proceed to step 1.5.

1.5 Repeat steps 1.2 to 1.4 for the opposite switch.

1.6 If it has been necessary to adjust either Drive or Detector rod ends, carry out NR/SMS/PartB/271 (Detector Test (Unistar)).

1.7 Restore the points to power.

1.8 Record the results of the FPL test on the record card.

1.9 Carry out a final check before completion of the work by asking the Signaller to operate the points to normal and reverse (twice if possible). Observe correct operation.

END

Includes:	Unistar HR
Excludes:	IBCL, RCPL and All Powered Point Machines and Mechanical points

GENERAL

Isolate the point machine by opening / turning the access lever on the hydraulic power pack. Select Normal or Reverse direction for manual operation. Disconnect the outgoing point detection from the DLD (Drive, Locking, Detection) unit or apply an alternative safe system of work (See NR/SMS/PartA/A04).

Gauges

a) 1.5mm & 3.5mm gauges for Toe drive positions.

b) 2mm & 4mm gauges for Supplementary drive positions.

1. DLD at Toe Position

1.1 Place the points on manual, and manually operate points to the normal position.

1.2 Check the correct voltage is present on the outgoing circuit (KR lines) for the closed switch on the links in the disconnection box.

1.3 Check the correct voltage is present on the outgoing circuit (KR lines) for the open switch on the links in the disconnection box.

1.4 Open the switch blade and insert the 3.5mm gauge between the stock and switch rail, aligned centrally to the detector rod at the normal position.

1.5 Manually operate the points and test that detection is broken, check that the witness marks on the detector plate are not visible.

1.6 Repeat using the 1.5mm gauge and test that detection is made, and the correct voltage is present.

1.7 Check that the witness marks on the Detector Plate are protruding such that the cover plate sits between the first and second witness mark. This equates to a detection position between 0mm and 2.5mm from switch closed position.

Where the witness marks (See Figure 1) indicate detection is being made between 2.5mm and 5mm (cover plate sits between second and third mark), adjust the detector bar to return the visible detection marks to sit between the first and second mark, equating to the 0mm to 2.5mm range.

Figure 1 - Detector Plate witness marks indicating optimal set up between marks for 0mm and 2.5mm

1.8 Repeat Tests 1.2 to 1.7 for reverse side.

1.9 If supplementary Drive DLDs are fitted, proceed to Step 2. Otherwise complete Step 3.

2. Supplementary Drive DLDs (if fitted)

2.1. Place the points on manual, and manually operate the points to the normal position.

2.2. Check that the correct voltage is present on the outgoing circuit for the closed switch.

2.3. Check that the correct voltage is present on the outgoing circuit for the open switch.

2.4. Open the switch blade and insert the 4mm gauge between the stock and switch rail, aligned centrally to the detector rod at the normal position.

2.5. Manually operate the points and check that detection is broken. Check that the witness marks on the Detector Plate are not visible.

2.6. Insert the 2mm gauge between the stock and switch rail, aligned centrally to the detector rod.

2.7. Check that the witness marks on the Detector Plate are protruding such that the cover plate sits between the first and second witness mark. This equates to a detection position between 0mm and 2.5mm from switch closed position.

Where the witness marks indicate detection is being made between 2.5mm and 5mm (cover plate sits between second and third mark), adjust the detector bar to return the visible detection marks to sit between the first and second mark, equating to the 0mm to 2.5mm range.

2.8. Repeat Tests 2.2 – 2.7 for the reverse position.

2.9. Repeat tests 2.1 to 2.8 for each supplementary drive DLD.

3. Final Checks

3.1 Replace all covers / lids and latch securely.

3.2 The final check before completion of the work is to restore the points to power and ask the Signaller to operate the points to normal and reverse positions (twice if possible). Observe correct operation.

END

GENERAL

The tasks and tests stated in this section are to be carried out on equipment after incidents of flooding. If a piece of equipment is not covered below, inform your SM(S).

Equipment types

1. Train Operated Points (Hydro-Pneumatic).
2. Machine Operated Points.
3. Pneumatic Point Machines & Train Stops.
4. HPSS Point Systems.
5. Rail Clamp Point Lock.
6. Electrical Detectors.
7. Mechanical Fittings and Points.
8. Trackside Apparatus Cases & Equipment Rooms.
9. Electronic Equipment.
10. Rail / Sleeper Attached / Mounted Equipment.
11. Electrically Lit Signals.
12. Semaphore Signal Machines.
13. Operational Telephones.
14. Lever Frames, Lever Locks & Circuit Controllers.
15. Hydraulic Trainstops.
16. Automatic/Manually Controlled Level Crossing Equipment.
17. Mechanical Gated Level Crossings.

1. Equipment & Associated Action Required

Train Operated Points (Hydro-Pneumatic).

These use a closed hydraulic system.

1.1 Check the integrity of seals.

1.2 Check electrical connections for corrosion, contamination, and damage. Rectify or renew as necessary.

1.3 Carry out NR/SMS/PartB/Test/018 (Train Operated Points Detection Test).

1.4 Carry out NR/SMS/PartB/Test/052 (Dynamic Earth Test).

1.5 Test for correct operation and indication for normal & reverse positions.

2. Machine Operated Points

Includes:	HW, ML, MV- GRS Model 5, SGE HA, SGE HB, WBS 63, WBS M3 & M3A
Excludes:	All other Machine Operated Points

2.1 Clean and wipe contacts & terminal blocks.

2.2 Check electrical connections and terminal blocks for corrosion, contamination, and damage. Rectify or renew as necessary.

2.3 Clean and wipe parts that have a moving metal-to-metal contact surface (gear wheels etc) and apply new lubricant (oil or grease as approved).

2.4 Clean and wipe motor bushes and commutator operate point motors and check for any excessive noise/sparking/smell.

2.5 The electromagnetic clutch of HW2000s could have become blocked by silt. Attempting to operate the points might reveal any problems, renew as required.

2.6 Carry out NR/SMS/PartB/Test/001 (FPL Test Machine).

2.7 Carry out NR/SMS/PartB/Test/011 (Electrical Detection Test - Machine).

2.8 Carry out NR/SMS/PartB/Test/019 (Detection Loop Test).

2.9 Carry out NR/SMS/PartB/Test/052 (Dynamic Earth Test).

2.10 Test for correct operation and indication for normal & reverse positions.

3. Pneumatic Point Machines & Train Stops

Includes:	Point machine types WBS EP&D, SGE VB
Excludes:	All other Pneumatic Point Machines & Train Stops

The air main pump is the responsibility of the Plant Engineer who should confirm that this part of the system is working correctly.

3.1 Clean and wipe contacts & terminal blocks.

3.2 Check seals/gaiters for damage.

3.3 Clean air filters & exhausts.

3.4 Renew damaged/corroded items as required.

3.5 Wash and wipe parts that have a moving metal-to-metal contact surface (gear wheels, lock bars etc) and apply new lubricant (oil or grease as approved).

3.6 Remove accumulated water from the air supply (including supply main valves).

3.7 Bleed points might be provided. High-pressure air systems are prone to rapid corrosion due to the high concentration of oxygen.

3.8 Clean the oil filter and renew the lubricant.

Point Machines Only:

3.9 Carry out NR/SMS/PartB/Test/001 (FPL Test - Machine).

3.10 Carry out NR/SMS/PartB/Test/011 (Electrical Detection Test - Machine).

3.11 Carry out NR/SMS/PartB/Test/019 (Detection Loop Test).

3.12 Carry out NR/SMS/PartB/Test/052 (Dynamic Earth Test).

3.13 Test for correct operation and (point machines) indication for normal & reverse positions.

4. HPSS Point Systems

Includes:	ECU, LVDT, Motor & Brake
Excludes:	All other HPSS Point Systems

HPSS systems are designed to withstand submersion in up to one meter of water.

4.1 Check cable insulation, cable entry points, plug couplers and all electrical equipment for insulation damage and secure fitment.

4.2 Renew components as required.

4.3 Remove any obstructions on the torsion back drive.

4.4 Wash and wipe the nuts & thread on the lost motion drive if contaminated.

4.5 Carry out NR/SMS/PartB/Test/004 (FPL Test - HPSS).

4.6 Carry out NR/SMS/PartB/Test/052 (Dynamic Earth Test).

4.7 Test for correct operation and indication for normal & reverse positions.

5. Rail Clamp Point Lock

These use a vented hydraulic system.

5.1 If it is suspected the water level has risen above reservoir fill-hole level renew the pump unit, drain the hydraulic system, and compress the actuators to expel any fluid.

5.2 Renew the hydraulic fluid NR/SMS/PartB/Test/015 (Clamp Lock: Test for air in the system).

5.3 Check the pump unit electrical connections, terminal blocks, and mechanical components for corrosion, contamination, and damage. Rectify or renew as necessary.

5.4 Check the microswitch assembles, if they are of the ITW type, no further action is required.

5.5 If they are of any other type (e.g. Dowty), renew the microswitch assembles.

5.6 If you are in doubt about the type of microswitches, ask your SM(S).

5.7 Clean and apply new lubricants to the following on the open switch:

a) Fixed & adjustable cams.

b) Lock arm.

c) Locking piece.

d) Lock arm pivot.

5.8 Manually pump across and repeat on the other switch.

5.9 Carry out NR/SMS/PartB/Test/003 (Facing Point Lock Tests - Clamp Lock).

5.10 Carry out NR/SMS/PartB/Test/013 (Detection Test – Clamp Lock).

5.11 Carry out NR/SMS/PartB/Test/019 (Detection Loop Test).

5.12 Carry out NR/SMS/PartB/Test/052 (Dynamic Earth Test).

5.13 Test for correct operation and indication for normal & reverse positions.

6. Electrical Detectors

Includes:	BR998 type, Crewe type, LMS type, SGE type.
Excludes:	All other Electrical Detectors

6.1 Clean and wipe contacts & terminal blocks.

6.2 Check electrical connections and terminal blocks for corrosion, contamination, and damage. Rectify or renew as necessary.

6.3 BR998 detectors: Check the microswitch assembles; if they are of the ITW type, no further action is required.

6.4 If they are of any other type (e.g. Dowty), renew the complete detector.

6.5 If you are in doubt about the type of microswitches, ask your SM(S).

6.6 Wash and wipe parts that have a moving metal-to- metal contact surface and apply new lubricant (oil or grease).

6.7 As required, carry out :

a) NR/SMS/PartB/Test/010 (BR998 Detector Electrical Tests).

b) NR/SMS/PartB/Test/011 (Electrical Detection Test - Machine).

c) NR/SMS/PartB/Test/016 (Supplementary Detection Test).

d) NR/SMS/PartB/Test/019 (Detection Loop Test).

6.8 If not undertaken as part of the point actuator tasks.

6.9 Carry out NR/SMS/PartB/Test/052 (Dynamic Earth Test).

6.10 Test for correct operation and indication for normal & reverse positions.

7. Mechanical Fittings and Points

Includes:	Wire/Rodding runs, Cranks, Semaphore, Signal fittings, Mechanical detectors, Mechanical back drives, Point fittings.
Excludes:	All other Mechanical Fittings and Points

7.1 Check wire/rodding runs are free from any obstructions. Check all foundations are stable. Check all pulley wheels/roller wheels are free to move.

7.2 Pulley wheels & roller wheels shall not be lubricated, unless using a dry film lubricate.

7.3 Clean, wash and wipe all cranks/semaphore signal fittings. Fill the bearings with new lubricant. Check the crank/fitting for security and freedom of movement.

7.4 New grease shall be pumped in to expel the existing grease in the bearing.

7.5 Clean the bearing surfaces on oil lubricated cranks and flood the bearing with new oil. Check any bearing covers (e.g. 'Top Hats') are replaced or renewed if missing.

7.6 Excess grease and oil shall be wiped away.

7.7 Clean, wash and wipe all mechanical detectors.

7.8 Apply new lubricant to the detector slide and rollers.

7.9 Carry out NR/SMS/PartB/Test/012 (Detection Test – Mechanical).

7.10 Brush and wash all exposed screw threads, then wipe clean.

Mechanical points as required:

7.11 Carry out a NR/SMS/PartB/Test/002 (FPL Test Mechanical).

7.12 Test by operation all signals and points that are mechanically operated. Check correct indications / detection are given for each operating position of the equipment.

8. Trackside Apparatus Cases & Equipment Rooms

Includes:	Disconnection boxes, Lineside & Tail Cables, Multicore, Twin & single core Cables, terminal blocks & links, Internal single core wires, Power supplies, Fuses and holders, Relays, Contactors.
Excludes:	All other Trackside Apparatus Cases & Equipment Rooms

8.1 Clean and wipe all racking, shelving, casings/walls.

All cables, Wires, and Terminals:

8.2 Examine insulation, terminations, terminal blocks, and links. clean and wipe terminal blocks and links, renew if necessary. Renew crimps or re-terminate as necessary.

Internal Wires:

8.3 Examine length of wire, renew if insulation has been damaged / degraded or if all the wire has been totally submerged.

Lineside and Tail Cables:

8.4 Carry out NR/SMS/PartB/Test/054 (Cable Insulation Test).

8.5 Fuses and Fuse Holders: Remove each fuse in turn and check to see if it has blown. Clean and wipe the fuse holder. Replace with new fuses only after the equipment it feeds has been checked.

Power Supplies:

8.6 Examine transformers & transformer/rectifiers (TJ) for evidence of water penetration. Clean and wipe terminals and terminal blocks.

If the TJ contains electronics replace unit. Renew primary and secondary cells if it is suspected that water has risen above the vent/filling caps.

Busbars fitted with ELDs:

8.7 Carry out NR/SMS/PartB/Test/053 (ELD Test & Calibration).

Busbars without ELDs:

8.8 Carry out NR/SMS/PartB/Test/051 (Bus Bar Earth Test).

Relays and Relay Bases:

8.9 Remove relay and spade connectors. Clean and wipe relay base and spade connectors, renew if necessary. Renew relay and test for correct operation.

Timer relays:

8.10 Check each relay using NR/SMS/PartB/Test/061 (Relay Timer Test).

Contactors:

8.11 Clean and wipe terminals and contact faces. Examine components for corrosion, contamination and damage. Rectify or renew as necessary.

9. Electronic Equipment

Includes:	TPWS modules, HABD scanners, Inverters, UPS, SSI modules, Axle counter evaluators & lineside junction boxes (EAK).
Excludes:	All other types of Electronic Equipment.

TPWS Modules:

9.1 Clean and wipe terminations.

9.2 Examine each module by tilting forwards and inspecting the front 'window'. If no water is seen, the module is OK for continued use.

If water is seen, the module shall be replaced.

Other Electronic/Computer Scanners/Modules/Units:

9.3 Examine equipment. If water is known or suspected of entering the equipment, it shall be replaced.

10. Rail / Sleeper Attached / Mounted Equipment

Includes:	Treadles, TC equipment, AWS, ATP, TPWS OSS & TSS, TASS Balise, Axle counter rail contacts, HABD Transducers.
Excludes:	All other Rail / Sleeper Attached / Mounted Equipment.

Mechanical Treadles:

10.1 Renew treadle.

Freddy Treadle:

10.2 Clean and wipe terminations, test by operation.

Track Circuit Tuning Units:

10.3 Renew equipment.

Track Circuit Connections and Bonds:

10.4 Clean and wipe the connections as necessary. Check the security of the connections and any clips or orange pipe used, renew if necessary.

Check if orange pipe is used that any accumulated water has drained off, rectify if necessary. Check the security of any fishplate bonds, renew if necessary. Check where any TC passes through a level crossing with Bomacs or other crossing surfaces.

Remove or flush out any trapped debris or other contaminates.

Older types of Bomacs have a metal band around them. Trapped metallic objects can easily short out the TC.

Insulated Rail Joints:

10.5 Carry out NR/SMS/PartB/Test/041 (Insulated Rail Joint (IRJ) Tests).

Impedance Bonds:

10.6 Check rail terminations, termination box and/or connection points. Clean and wipe as necessary. Test the bond as per Track Circuit Test (250 to 263) at NR/SMS/PartB/Index.

All Track Circuits:

10.7 Carry out a full Track Circuit Test (250 to 263) NR/SMS/PartB/Index.

AWS Equipment:

10.8 Clean and wipe as necessary.

10.9 Check the security of the magnets and ramp.

Check the termination box on the electro / suppressed permanent magnet, clean and wipe terminations and links.

Renew crimps and connections if necessary.

10.10 Carry out NR/SMS/PartB/Test 024 (AWS Tests).

ATP (GWML) Equipment:

10.11 Check the Beacon, infill loop and termination boxes for damage and security, clean and wipe terminations and links.

Renew crimps and connections if necessary.

Test the loop resistance, renew if necessary.

ATP (Chilterns) Equipment:

10.12 Renew the loop electronics unit. Check the loop and termination boxes for damage and security. Clean and wipe terminations and links.

Renew crimps and connections if necessary.

10.13 Carry out NR/SMS/PartB/Test/029 (ATP Equipment (Chilterns) Loop Test).

TPWS OSS & TSS:

10.14 Check the OSS and/or TSS loops and associated disconnection boxes for damage and security, renew if necessary.

Clean and wipe terminations and links.

Renew crimps and connections if necessary.

10.15 Carry out NR/SMS/PartB/Test/230 (Train Protection and Warning system (TPWS) Tests).

Balise (All types):

10.16 Check for damage and security.

10.17 Replace if necessary.

HABD Transducers:

10.18 Check for damage, security and alignment. Replace if necessary.

Axle Counter Rail Contacts (Count Heads):

10.19 Check for damage and security, carry out NR/SMS/PartB/Test/045 (Thales Axle Counters Dummy Wheel Test – AxLM & AzLE) or NR/SMS/PartB/Test/042 (Axle Counters Dummy Wheel Test - AzL 70, 70/30, 70/30S). Replace as necessary.

11. Electrically Lit Signals

Includes:	Ground mounted repeaters, Position light signals, Signal post replacement switches, Mechanical disc signals, Stencil indicators, Theatre indicators, Internally lit LOS signals.
Excludes:	All other Electrically Lit Signals

11.1 Clean and wipe interior of signal head, lamp holders, transformers, terminals, terminal bocks and links. Examine crimps and terminations, renew if necessary.

11.2 Remove lens(es)/stencil(s) (internal and external as applicable), Clean and wipe or renew as required.

11.3 Wash and wipe lamps, renew as required.

Signal post replacement switch (SPRS):

11.4 Clean and wipe interior, terminations and terminal bocks.

Examine crimps and terminations, renew if necessary.

11.5 Carry out NR/SMS/PartB/Test/023 (Other Signal Tests).

11.6 Renew EKR relay (if applicable).

11.7 Test as required:

a) NR/SMS/PartB/Test/021 (Filament Signal Lamp Tests).

b) NR/SMS/PartB/Test/022 (Signal Lamp and Light Module Proving Tests).

12. Semaphore Signal Machines

Includes:	BP, GRS, SGE, WBS
Excludes:	All other Semaphore Signal Machines

12.1 Clean and wipe interior, circuit controller (if applicable) terminations and terminal blocks. Examine crimps and terminations, renew if necessary.

12.2 Wash and wipe surfaces that have a moving metal-to-metal contact surface (gear wheels, bearings etc) and apply new lubricant.

12.3 Clean and wipe motor bushes and commutator operate motor and check for any excessive noise/sparking/smell. Renew if necessary.

12.4 Check, if fitted, leather brake pads for condition. Renew if necessary.

12.5 Test for correct operation and indication for On, Off and Wrong positions.

13. Operational Telephones

Includes:	SPTs, Point zone telephones, Level crossing telephones, Lineside direct line telephones
Excludes:	All dial telephones and plug points connected to exchanges.

13.1 Replace telephone using the correct TMTH Test Plan.

13.2 Carry out NR/L3/TEL/30181/011 - Maintenance of Operational Telephones.

14. Lever Frames, Lever Locks & Circuit Controllers

Includes:	All types of mechanical locking signal box, ground frames, Electrical locks and combined locks, Circuit controllers.
Excludes:	All other Lever Frames, Lever Locks & Circuit Controllers.

14.1 If water has entered any locking boxes, report it to your SM(S).

The lids of any locking boxes are not to be removed unless you are requested to do so by your SM(S).

14.2 Wash and wipe frame structure, levers, catch handles, catch rods, and locking connections. Check all components are undamaged and secure.

14.3 Report any damage to your SM(S).

14.4 Wash and wipe exteriors of lever locks and circuit controllers.

14.5 Clean and wipe interior, terminations, and terminal blocks.

14.6 Examine crimps and terminations, renew if necessary.

14.7 Clean contact faces or bands/fingers in circuit controllers.

14.8 Wash and wipe surfaces that have a moving metal-to-metal contact surface and apply new lubricant.

14.9 Test by operation the electrical release(s) and mechanical interlocking of the lever frame.

Simple ground frames (i.e. 1 releases 2, 2 reverse locks 1) can be tested using the layout diagram or plate legends. Complex signal box frames require an experienced tester.

15. Hydraulic Trainstops

These use a vented hydraulic system.

15.1 If it is suspected the water level has risen above reservoir fill-hole level renew the pump unit, drain the hydraulic system and expel any fluid. Renew the hydraulic fluid.

15.2 Check the mechanical components for corrosion, contamination and damage. Rectify or renew as necessary.

16. Automatic/Manually Controlled Level Crossing Equipment

Includes:	AHBC, ABCL, AFBCL, AOCL, AOCL+B, AOCR, MSL, MCB, OCB, Rural Barriers, Boom gates, Hydraulic and mechanical barrier units.
Excludes:	All other Automatic/Manually Controlled Level Crossing Equipment

Hydraulic Barrier Units:

16.1 Clean and wipe interior of unit. If it is suspected the water level has risen above reservoir fill-hole level renew the pump unit.

16.2 Drain the hydraulic system and expel any fluid.

16.3 Check the condition of seals and gaiters on the rams.

16.4 Remove then wash and wipe ram pins.

16.5 Lubricate the ram pins and main bearings with new grease/oil.

16.6 Check the ram and boom for security and freedom of movement. Clean and wipe motor bushes and commutator.

16.7 Clean and wipe terminal blocks, renew if necessary. Renew crimps or re-terminate as necessary.

16.8 New grease shall be pumped in to the grease nipples to expel any existing grease.

BR 843 units are fully self-contained; renewing the unit by default, renews all the hydraulic and internal electrical components.

Mechanical Barrier Units:

16.9 Clean and wipe interior of unit.

16.10 Check electrical connections and terminal blocks for corrosion, contamination and damage. Rectify or renew as necessary.

16.11 Clean and wipe parts that have a moving metal-to-metal contact surface (gear wheels etc) and apply new lubricant.

16.12 Clean and wipe motor bushes and commutator. Renew crimps or re- terminate as necessary.

Boom Gates:

16.13 If it is suspected that the boom gate motor or gearbox has been partially or totally submerged, then the complete unit shall be changed.

16.14 Check electrical wiring and plugs for corrosion, contamination and damage. Rectify or renew as necessary.

16.15 Check clutch operates correctly, repack universal joints and wheel bearing with new grease.

16.16 If it is suspected that any limit switches in the hinge assembly might have been submerged, then change the limit switches.

16.17 Clean and wipe contacts & terminal blocks in hinge assembly. Re-grease hinge bearings.

16.18 If it is suspected that the control cubicle has been totally or partially submerged, then change the control plate.

16.19 Carry out NR/SMS/PartB/Test/052 (Dynamic Earth Test). Not NER mechanical barrier units.

16.20 Test the sequence of crossing operation hand, local and automatic operation as applicable for automatic crossings.

16.21 Check hand, local and signal box operation as applicable for manual crossings.

17. Mechanical Gated Level Crossings

Includes:	Wheel operated, Hand operated, Gate locks, Wicket gates.
Excludes:	All other Mechanical Gated Leve Crossings.

17.1 Check rodding runs are free from any obstructions.

17.2 Check all foundations are stable. Check all roller wheels are free to move.

17.3 Clean, wash and wipe all cranks. Fill the bearings with new lubricant. Check the crank for security and freedom of movement.

17.4 New grease shall be pumped in to expel the existing grease in the bearing.

17.5 Excess grease shall be wiped away.

17.6 Clean and wipe gate locks interiors.

17.7 Care shall be taken when removing the covers of gate locks, components and springs might fly out.

17.8 Clean, wash and wipe wicket gate mechanisms.

17.9 Apply new lubricant to sides.

17.10 Clean, wash and wipe gate stops housings and internal mechanism. Lubricate with oil.

17.11 Check that all debris and contaminates are cleaned from around the top slots of the stops. Any small obstruction could cause the stops not to rise and fall correctly.

17.12 Test gate and locking operation to the Signaller’s satisfaction.

17.13 The final action for all equipment is to test for correct operation.

END

This test is solely part of a maintenance service and shall not be used in place of the token tests mandated under the provisions of NR/SMTH.

This test is to prove the integrity of an individual token system as a whole, whereas Services A&B are specific services on individual instruments.

In order to carry out this test it will be necessary to take possession of the system.

A token shall NOT be withdrawn for the purposes of any possession.

If the work is to be carried out on a line open for traffic, and working by Pilotman has been arranged, the Pilotman SHALL NOT BE GIVEN A TOKEN.

Access will not be available to sidings worked by a ground frame released by the token during the period of the test.

Staff will need to be positioned at each terminal instrument throughout the duration of the system test, and at each other instrument whilst that specific instrument is under test.

During testing of Intermediate/Auxiliary instruments, both galvanometers/indicators shall operate before when attempting to electrically withdraw a token. Failure to check this will invalidate the test.

One person on site shall take overall direction of the system test.

Steps 1.9 to 1.26 do NOT apply to systems which either (a) wholly use BR 930 series relays for polar functions, or (b) where the transmission between sites is by means of Reed Vital FDM equipment.

1. Test

1.1 Prove that the system is in phase by electrically releasing one token from the system.

1.2 Replace the token into the instrument.

1.3 Check that the correct number of tokens is present in the system.

1.4 Unlock each instrument and manually withdraw all tokens.

1.5 Check each token for correct colour and labelling.

1.6 Check the bearing faces and keyways of each token for excessive wear.

1.7 Replace all the tokens into the instruments from which they were withdrawn.

1.8 Prove that the system is in phase by electrically releasing one token from the system.

1.9 If the token system is NSKT with a diode is provided in series with the AZR at the remote end, arrange to have the diode strapped out for the duration of the testing.

From the signal box end controlling instrument Check that the strap is effective by electrically releasing a token, and then pressing and releasing the plunger, verifying that the galvanometer/indicator re-operates for a few seconds after the plunger has been released.

Replace the token into the instrument.

1.10 Designate one instrument as the instrument under test.

1.11 Arrange for an electrical release to be made to the instrument under test for steps 1.12 to 1.16.

If the system is NSKT, several successive releases might be needed to carry out the various tests

1.12 Check that the voltage on the lock relay coil (R1/R2) is between 12 – 16 volts. For Intermediate/Auxiliary instruments repeat for the other relay.

1.13 If a voltage in step 1.12 is in excess of 16 volts, inform your SM(S) to arrange for the insertion of suitable resistors in series with the relay coil. If the voltage is in excess of 24 volts, the relay must also be changed within 3 months.

1.14 Check that the voltage on the lock coil is between 12-15 volts.

1.15 Electrically withdraw a token from the instrument under test.

1.16 Check that another token cannot be electrically withdrawn from the instrument under test.

1.17 Replace the token into the instrument from which it was withdrawn.

1.18 Withdraw a token from another token instrument.

1.19 Check that another token cannot be electrically withdrawn from the instrument under test.

1.20 Replace the token into the instrument from which it was withdrawn. If the instrument under test is a terminal instrument go to step 1.24

1.21 Withdraw a token from a different instrument from that used in step 7.18, and which is in the towards the other end of the section beyond the instrument under test.

1.22 Check that another token cannot be electrically withdrawn from the instrument under test.

1.23 Replace the token into the instrument from which it was withdrawn.

1.24 Repeat steps 1.10 to 1.23 in turn for all other token instruments in the system.

1.25 Close and re-lock all instruments.

1.26 If a diode was strapped out as set out in step 9, remove the strap.

1.27 Check that a token can be released from an instrument.

1.28 Replace the token.

END

This check is not a full “Signal Sighting Inspection”, full signal sighting shall only be carried out by a person holding the appropriate competency.

If a visibility issue is recorded during a check that you are unable to rectify then your SM(S) shall be advised

The Formula for Speed & Distance Measurements can also be found in NR/SMS/PartZ/Z01 – Signal Reference Values.

The Signal Visibility Check is split into 4 Section’s use the flow chart in figure 1 to determine which test is required.

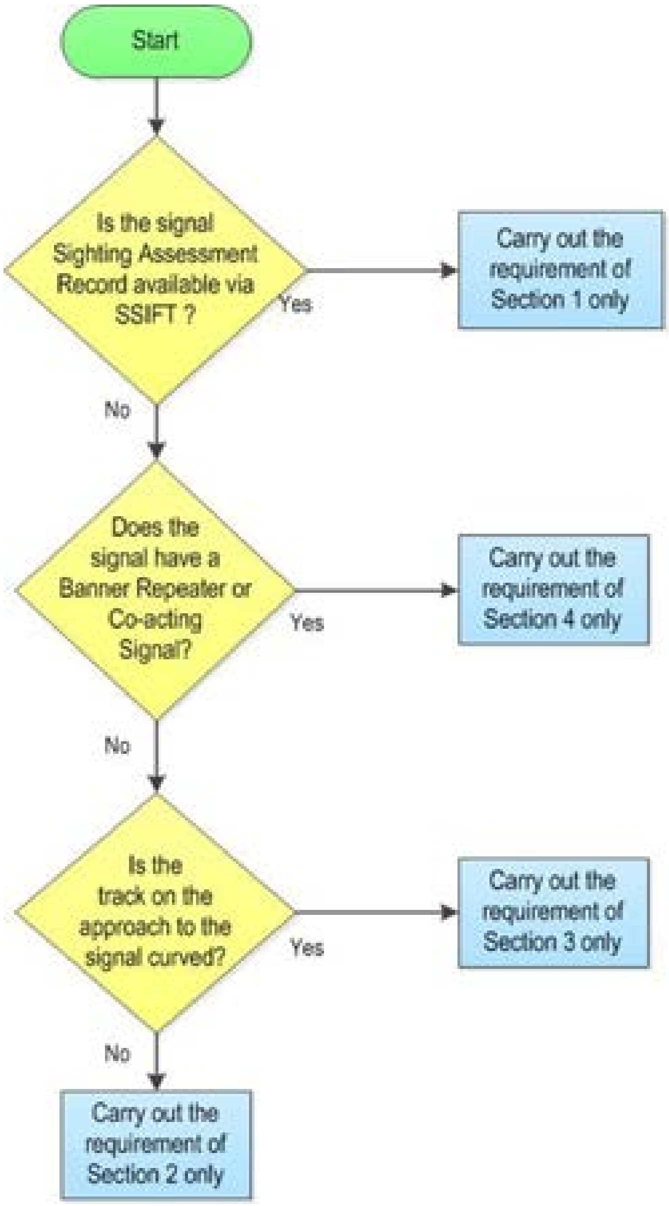

Figure 1 - Decision Flowchart

1. Signal Sighting Assessment Record (preferred option)

The contents of the latest “Signal Sighting Assessment Records” are now available to all via the SSIFT App.

1.1 Access the Signal Sighting details of the relevant signal via the SSIFT App.

1.2 Check the signal from the required reading distance detailed on the signal sighting assessment record and record the visibility on the record card.

1.3 The removal of small areas of vegetation, that are affecting the signal visibility of the signal aspects, are the responsibility of the signalling technician.

If the area to be cleared is more extensive, then the SM(S) shall be informed.

2. Signal Sighting Assessment Record Unavailable – Track approaching the signal is not curved

2.1 Identify the maximum line speed at which the signal can be approached.

2.2 Using Signal Visibility Chart (10 seconds) in NR/SMS/PartZ/Z01 – Signal Reference Values, work out the distance on the approach side of the signal at which the Viewing Point is located.

2.3 From a position in line with the right-hand edge of the signal head, observe there is no obscuration between your location and the Viewing Point.

If there are no obstructions between the signal and viewing distance, there is no requirement to walk out to the Viewing Point.

2.4 If there are any obstructions, the signal shall be viewed from the Viewing Point and the degree of those obstructions recorded on the record card. The SM(S) shall be advised.

2.5 The removal of small areas of vegetation, that are affecting the signal visibility of the signal aspects, are the responsibility of the signalling technician. If the area to be cleared is extensive, then the SM(S) shall be informed.

3. Signal Sighting Assessment Record Unavailable – Track approaching the signal is curved

3.1 Identify the maximum line speed at which the signal can be approached.

3.2 Using Signal Visibility Chart (10 seconds) in NR/SMS/PartZ/Z01 – Signal Reference Values, work out the distance on the approach side of the signal at which the Viewing Point is located.

3.3 Walk to the Viewing Point and observe there is no obscuration between your location and the signal.

3.4 The removal of small areas of vegetation, that are affecting the signal visibility of the signal aspects, are the responsibility of the signalling technician. If the area to be cleared is more extensive, then the SM(S) shall be informed.

4. Signal Sighting Assessment Record Unavailable – The Signal fitted with a banner repeater or co-acting signal. And at a banner repeater or co-acting signal

4.1 Identify the maximum line speed at which the signal can be approached.

4.2 Using Signal Visibility Chart (5 seconds) in NR/SMS/PartZ/Z01 – Signal Reference Values, work out the distance on the approach side of the signal at which the Viewing Point is located.

4.3 From a position in line with the right-hand edge of the signal head, observe there is no obscuration between your location and the Viewing Point.

If there are no obstructions between the signal and the Viewing Point, there is no requirement to walk out to the Viewing Point.

4.4 If there are any obstructions, the signal shall be viewed from the Viewing Point and the degree of those obstructions recorded on the record card. The SM(S) shall be advised.

4.5 The removal of small areas of vegetation, that are affecting the signal visibility of the signal aspects, are the responsibility of the signalling technician. If the area to be cleared is more extensive, then the SM(S) shall be informed.

END

Technical Instruction

Issue date: 16th November 2023
Compliance date: 16th November 2023
Expiry date: 15th November 2024

Technical Instruction TI 182 is attached to this standard/control document.

This Technical Instruction mitigates an urgent safety/asset/equipment risk that cannot await a full review of this standard/control document.

This standard/control document will be reviewed and reissued before the emergency change expires on 15th November 2024.

GENERAL

This apparatus forms part of the pilot scheme for Automatic Train Protection Systems.

Any maintenance or operating difficulties shall be reported to your SM(S) as corrective maintenance.

An ATP site can include:

a) ATP enclosure containing encoding equipment and ATP interface equipment, which is incorporated with existing signalling apparatus.

b) Beacon with disconnection box and cables.

c) Infill loop with TDA and RDA boxes and cables.

SERVICE A

1. ATP Enclosure

1.1 Remove any fire risks (e.g. oily waste, paper etc.) from the vicinity of the enclosure.

1.2 Check for security and signs of damage.

1.3 Dust and Examine interior.

1.4 Check the security of accessible terminals and cable glands and look for signs of water ingress.

1.5 Check the effectiveness of the door seal and ELDON latches and lock in keeping the door seal tight against the enclosure. Adjust as necessary.

1.6 Lubricate locks, latches & hinges.

1.7 Examine surge arrestors.

1.8 Examine earth connections. If in doubt, Test continuity and resistance.

1.9 Check the integrity of all lead seals and wire locking.

1.10 Check the two parameter plugs are securely chained to the enclosure.

2. Power Supply module

2.1 Check the green LED is lit on the front face of the power supply module.

This indicates that there is 110Vac input.

Any other indication means there is a fault condition and shall be investigated.

3. Beacon

3.1 Examine beacon, mounting and protection plate(s).

3.2 Remove any fire risks (e.g. oily waste, paper etc.) from the vicinity of the beacon, junction box and cables.

3.3 Check that the beacon and protection plate(s) are correctly aligned and positioned, Check that there is clearance between the protection plate(s) and the beacon.

3.4 Check all fixings for tightness.

3.5 Check the beacon disconnection box is properly fixed to the mounting stake and look for signs of water ingress.

3.6 Examine the terminals inside the disconnection box. Clean and Protect as necessary.

3.7 Examine cables and glands for security and damage.

3.8 Test the beacon signal level.

4. Infill Loop

4.1 Where practicable, Examine full length of loop cable. Pay attention to fixings and signs of stretching. Rectify minor sheath damage with self-amalgamating tape. Report damage that is more serious as corrective maintenance.

4.2 Remove any fire risks from the vicinity of the loop.

4.3 Examine the RDA and TDA boxes for damage, water ingress and security. Check the condition of the lid seal. Examine the terminals; Clean and Protect as necessary. Examine cable glands for security

4.4 At the TDA box, disconnect the loop cable from either t3 or t4 and measure the loop resistance. If the result is outside the range 340-400Ω, report it to your SM(S).

4.5 Test the loop signal level.

End

Includes:	ATP Fitted on the Chiltern Lines
Excludes:	ATP Fitted on the Great Western Main Line

General

Before removing any plug-in unit, anti-static precautions shall be taken. Either wear an approved earthing band or touch the bare metalwork of the associated rack or cabinet with your bare hands to discharge any static electricity within yourself.

When removing or inserting a board, do not touch the board, its tracking, or components.

Always use the handles provided. When not plugged into the operational ATP equipment, store boards in an anti-static bag or box.

An ATP site can include the following:

- Loop electronics unit (LEU).
- Loop.
- Simple signal interface or complex signal encoders, which are incorporated with the signalling apparatus.

SERVICE B

1. Loop

1.1 Remove any fire risks (e.g. oily waste, paper etc.) from the vicinity of the loop.

1.2 Remove vegetation as required.

1.3 Remove any metallic debris from the vicinity of the loop. Report any redundant rails in the 4ft, likely to damage the loop, for removal.

1.4 Examine full length of loop cable, paying particular attention to fixings, transposition covers and signs of chafing or damage.

1.5 Remove any ballast covering the loop.

2. Loop Electronics Unit (LEU)

All readings shall be taken using a digital voltmeter (DVM).

2.1 Examine the bonding connection between the LEU Housing and the signalling apparatus case and, if in doubt, test continuity and resistance using a DVM.

2.2 Remove any fire risks (e.g. oily waste, paper etc.) from the vicinity of the LEU.

2.3 Check the LEU for security and signs of damage. Report any damage as corrective maintenance.

2.4 Examine the cables and glands for security and damage.

3. Operational Checks

3.1 Observe the LEDs on the following boards; Check they are indicating as shown in Table 1:

Board	LED	State
Telegram Generator	1 and 2	Alternate Flashing
Telegram Generator TSR (if fitted)	1 and 2	Alternate Flashing
Modulator/Output	1	Steady illuminated

Table 1 - Indications

3.2 If the modulator/output LED is not illuminated or is flickering, then carry out NR/SMS/PartB/Test/029 (ATP Equipment (Chilterns) Loop Test) shall be carried out.

END

Includes:	AWS Permanent, Electro Magnets, Suppressed Magnets and PSR magnets maintained signal maintenance
Excludes:	Temporary ESR Magnets

General

If the AWS spark quench is fitted on the internal side of the electro-inductor feed links, check the electro-inductor is fully discharged before you touch the external side of disconnected links.

You can find more information about AWS equipment in NR/GN/SIG/19040.

SERVICE A

1. External Inspection

1.1 Remove debris from the area of the magnet and inductors.

1.2 Examine permanent magnets, electro-magnets and suppressor magnets for damage.

Arrange for repair or replacement where necessary as corrective maintenance.

1.3 Examine protection ramps and fixings. Components should be undamaged and secured to the sleepers.

1.4 Check the magnets are correctly aligned they should be approximately central to, and parallel with, the running rails.

1.5 Check the signal aspect is clearly visible from the magnet and is not being obscured (e.g. foliage).

1.6 If provided, visually check that any disconnection boxes are stable, securely fixed, and the lid or cover is fitted and (if provided) padlocked.

1.7 If provided, check that the plug coupler is free from damage and securely latched.

SERVICE B

2. Full Inspection and Test

2.1 Examine the termination box and seal on electro- magnets and suppressor magnets.

2.2 Examine cable terminations. Clean and protect as necessary.

2.3 If a failure is reported with the AWS, check that the suppressed permanent and electro magnets are correctly wired for their relevant voltage operation as detailed in NR/SMS/PartZ/Z08 (Train Protection - Reference Values).

2.4 Check tail cable is not damaged and is securely terminated. Tail cables should be protected by orange pipe or secured to sleepers.

2.5 Gauge the top of the AWS magnet with respect to rail head (±12mm from rail level). This should be done by use of a line / bob weights and associated plastic gauge or rule.

2.6 Carry out NR/SMS/PartB/Test/024 (AWS Tests).

3. Disconnection Boxes (if Provided)

3.1 Remove the lid and check the following:

a) Cables and cores are undamaged, correctly labelled, and free from wet or dry wire degradation.

b) Terminations for security, corrosion, arcing, and risk of short circuit/disconnection. Protect as necessary.

c) Cable glands are fitted and effective.

3.2 Refit the lid and (if provided) padlock, check they are fitted securely.

SERVICE RA Carry out service A of this SMS.

SERVICE RE Fix on failure.

END

Includes:	Vortok Depot Test Magnets
Excludes:	All other permanent magnets or electromagnets associated with automatic warning systems (AWS)

General

More information on this equipment can be found in the Vortok Depot Test Magnet Installation Manual.

Standard strength depot test magnets are coloured yellow. Extra strength depot test magnets are coloured green.

SERVICE B

1. Depot Test Magnet

1.1 Remove debris from the area of the magnet.

1.2 Examine the magnet for damage. Arrange for repair or replacement where necessary.

1.3 Examine the fixings. The equipment shall be secure.

1.4 Check the magnet is positioned correctly with respect to rail level.

1.5 Gauge the top of the magnet with respect to rail head (±1mm from rail level). This should be done by use of a line/bob weight and associated plastic gauge or rule.

To adjust the height of the magnet:

a) Loosen the magnet locking bolt.

b) Rotate the entire magnet assembly.

c) Tighten the locking bolt onto the nearest flat.

PERIODIC TASKS

2. Unit Calibration

2.1 Replace the magnet with a Vortok exchange unit.

Installation details are in the Vortok Depot Test Magnet Installation Manual

END

1. Working on Axle Counter Equipment

The Signaller at the monitoring signal box shall be informed before any work is done that affects the correct operation of the axle counter or can put it into a disturbed state.

For full evaluator testing, possession of the axle counter section and any signalling functions carried over the evaluator transmission links (if applicable) should be taken.

Results of all tests shall be recorded on the appropriate system's record card.

A standard Isolation/Re-set/Restoration form can be found under SMF/SG/0246.

2. Isolation of Axle Counters

Axle counters shall be isolated from the signalling equipment they are connected to before any work is carried out that disrupts their normal operation. This can only be done with the permission of the Signaller. Some systems might require the filling in of part A of the restoration form.

The isolation methods can vary depending on the type of axle counter; generally this is achieved by disconnection of the TPR link or data output from the evaluator.

The Signaller at the monitoring signal box is responsible for manual protection arrangements of the signalling during any period of isolation of the axle counter.

3. Re-setting and Restoration to Service of Axle Counters

This can vary depending on the type of axle counter system design but generally falls into four categories:

A. Technician
B. Co-operative
C. Signaller
D. Non co-operative (Scotland Only)

A: Technician

With this method, the Technician re-sets and restores to service the axle counter with permission of the Signaller. Some systems might require filling in of the restoration form.

B: Co-operative

With this method, the Technician re-sets and restores to service the axle counter in co-operation with the Signaller (both operating a function at the same time). Some systems might require filling in of the restoration form.

C : Signaller

With this method, the Signaller undertakes both re-setting and restoring the axle counter.

In all cases, the Signaller is responsible for confirming the axle counter section is clear before it is restored.

D : Non co-operative (Scotland Only)

Includes:	Newtonhill 113T, Dundee - Carnoustie 656T, 647T, Barassie Line 191T, Belmont - Kilkerran 669T
Exclude:	All Co-operative resets and other sites without co-operative resets

4. Release

4.1 Before starting work the Technician shall contact the Signaller and reach an agreement as to which track section he wishes to work on.

4.2 When the Signaller knows the track section to be clear and that no movement is authorised past the protecting signal, he can give authority to the Technician to work on axle counter.

4.3 On receipt of this authority, the Technician shall slip the disconnection link between the Axle Counter and the output TPR. This is to be recorded by both the Signaller and Technician.

5. Reset

5.1 Prior to final resetting of the axle counter the Technician shall obtain the assurance of the Signaller that the track circuit section is clear of traffic.

5.2 When the Technician has received verbal authority to reset the axle counter, he/she should follow the local procedure for resetting the axle counter evaluator. This normally requires the operation of a key operated switch and a push button switch.

5.3 Check the axle counter is fault free and can be Reset.

5.4 For AzL70 type axle counters, if the ‘G10’ LED is lit on the GRDFR card then press button T1 on this card, to extinguish the indication, before resetting is possible.

6. Adjustment

6.1 Usually, after the Axle Counter has been reset, the Technician then initiates restoration.

6.2 Before contacting the Signaller for permission to restore the track section, the Technician shall check that the axle counter is reset and in working order.

6.3 The Technician shall complete Part 3 of Form SMF/SG/0246 (Restoration of Axle Counter). This requires the Technician to give an assurance to the Signaller that the work is complete. The entry made shall be dictated to the Signaller, who will complete a similar form. The date and time of the message should be recorded.

6.4 The Technician shall contact the Signaller and request to carry out the restoration of the axle counter. The Technician should assist by establishing, where possible, that the section of line is clear.

6.5 The Signaller shall then complete Part 2 of his form and dictate this section to the Technician to restore the specified axle counter to permit movements over a specified section of line.

The Technician should record the dictated message in Part 2 of the form, noting date, time and the serial number that the Signaller has allocated to the form.

6.6 The Technician shall then restore the Axle Counter by reinstating the link between the Axle Counter and the output TPR.

6.7 When this is done, the Technician shall record on Part 3 of his form that the axle counter is restored, noting date, time and dictate the information to the Signaller. The Signaller should also make an entry in the Train Register at this stage.

6.8 During the restoration the Technician shall remain at the axle counter controls until advised by the Signaller that the equipment is properly returned to service.

6.9 The Technician's copy of the form shall be stored in a file adjacent to the axle counter equipment in the relay room. The Signaller's copy of the form should be sent to the Local Operations Manager.

6.10 The Serial Number allocated by the Signaller and details of the failure should be recorded on the Signalling Failure Report Form or given to Fault Control.

Form SMF/SG/0246 (Restoration of Axle Counter), is reproduced in Appendix A of this standard as specimen copies only:

Copies of Form SMF/SG/0246 (Restoration of Axle Counter) can be obtained, in book form.

Appendix B contains a process flowchart

7. Thales systems

On earlier Thales systems check after re-setting and restoration the ZIANZG card (if fitted) shows zero and the LED on the appropriate indicator shows ‘section clear’ (green).

If the evaluator-reset button is fitted with a lockable cover, it shall be fitted with a lock.

Information on co-operative isolation, re-setting and restoration of axle counters at particular locations can be found in NR/SMS/PartB/Test/30. Other equipment specific details can be found in NR/SMS/Appendixes.

8. Positioning of Rail contacts

The requirement is that whenever an axle counter head is being reinstated under SMTH and there is any possibility that the design parameters determining the required position have changed, or the position needs rechecking (e.g. after re-railing or slews), the necessary checks are carried out.

To determine the correct position, you shall be competent to read the signalling plan with respect to clearance requirements, overlap lengths, timing points, signal replacements etc, which might define the limitations of the acceptable area.

You shall know the technical constraints of the axle counter system unless these are determined by preformed cable lengths. You shall consult with the Track Engineer regarding any constraints resulting from welds, joints, or check rails.

You shall be competent to measure clearance points in accordance with GK/RT0011 Appendix A (1970mm between the running edges for the fouling point and 4880mm back to clearance unless it is a special, in which case there may be something in the records).

If you are in any doubt the position of rail contacts, ask your SM(S).

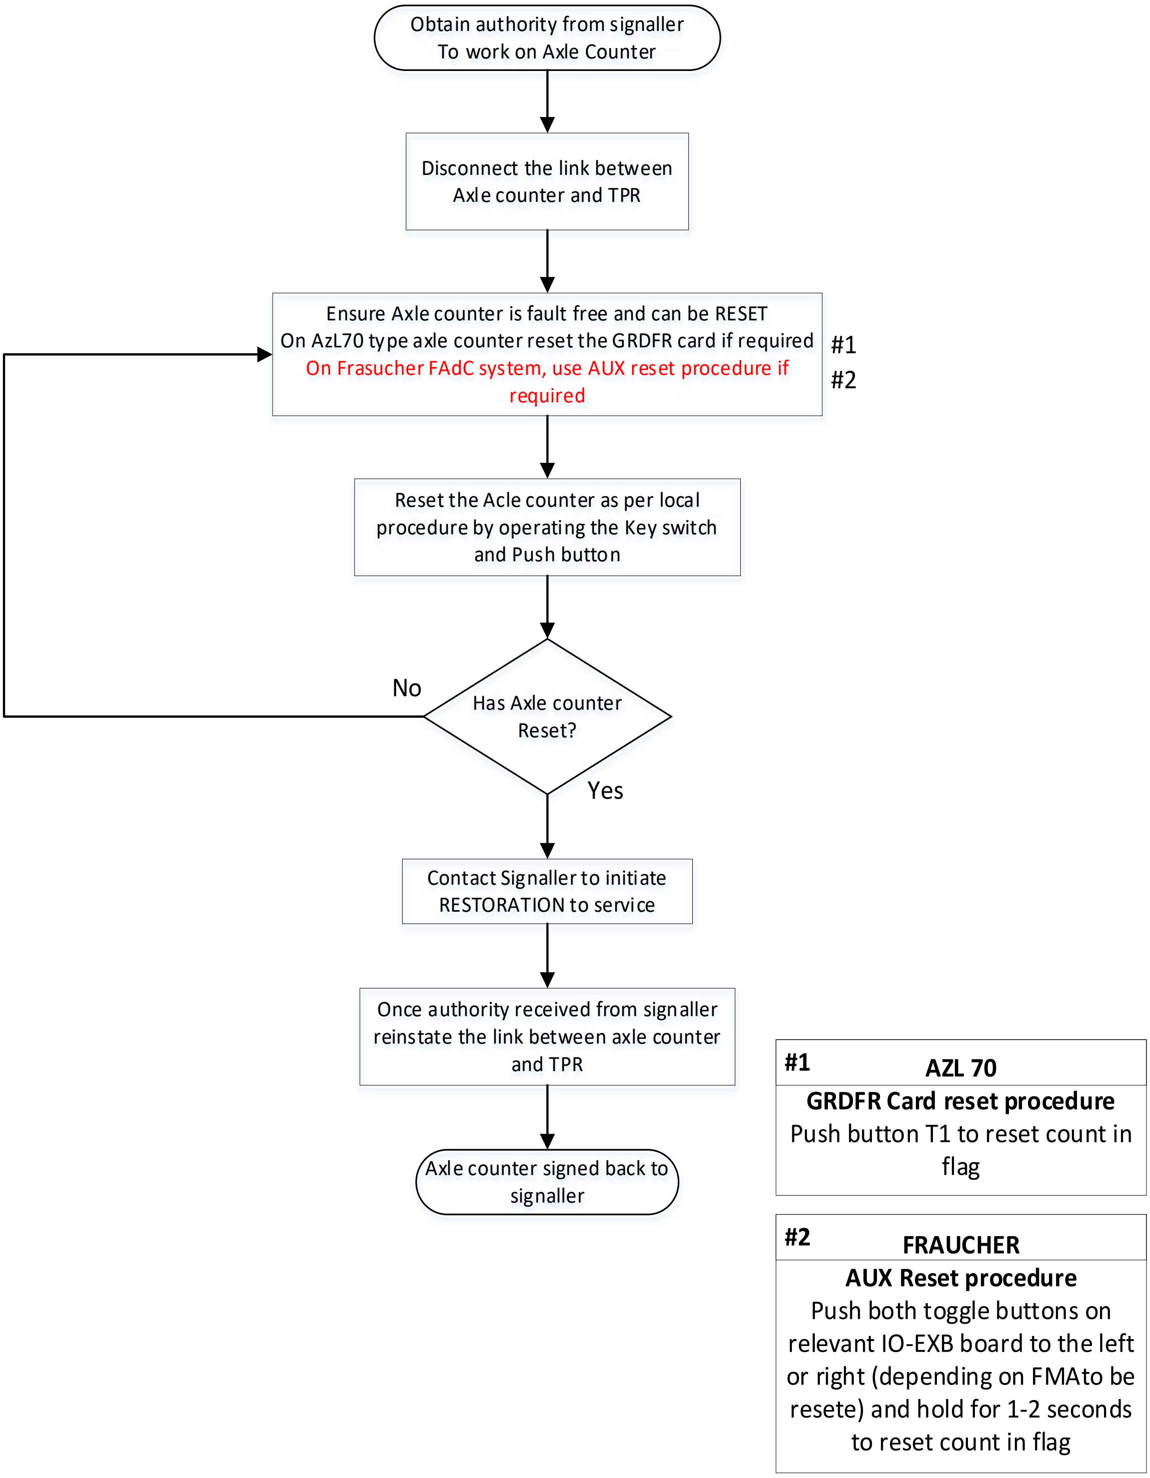
Appendix B: Flowchart

PROCEDURE FOR RESETTING AND RESTORING AN AXLE COUNTER WITHOUT CO-OPERATIVE RESTORE



END

Includes:	AzL70 Single Rail Contact 4 Wire TX System with EAK Lineside Junction Box and AzL70 Evaluator AzL70 Double Rail Contact 2 Wire TX System with EAK30 Lineside Junction Box and modified AzL70 Evaluator
Excludes:	All other types of Axle Counter

GENERAL

Make sure that metallic objects are kept away from the rail contacts as they can cause a false count.

Always take possession of the axle counter before adjusting the rail contacts.

If you have to reset the axle-counter, you shall follow the rules in NR/SMS/PartB/Test/030 (AzL Axle Counters : Isolate, Reset & Restore Procedures).

Measure and record all readings on the NR/SMS record card.

Always complete the tests on the lineside equipment before carrying out adjustments to the evaluator.

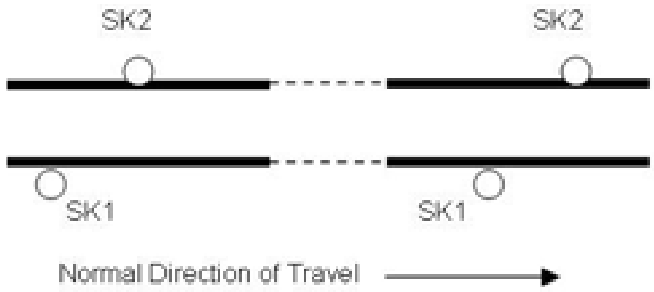


Figure 1 – Typical Layout of Single Rail Contact Type (SK11 Heads)

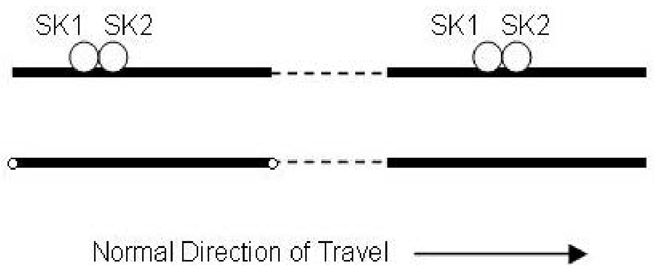

Figure 2 – Typical Layout of Double Rail Contact Type (SK30 Heads)

SERVICE A

1. Rail Contacts

1.1 Examine the count heads, rail insulations and bolts.

1.2 The TX head shall not touch the rail head. If a head or fixing is loose, check alignment NR/SMS/PartB/Test/042 (Axle Counters Dummy Wheel Test - AzL 70, 70/30, 70/30S) and tighten bolts NR/SMS/PartZ/Z03 (Train Detection - Reference Values).

1.3 Examine all tail cables, connections and clamps.

1.4 Check the protection plates and flux plates are tight, if fitted.

2. Lineside Junction Box (Types EAK and EAK30)

2.1 Examine the lineside junction box including all cables and connections.

2.2 Check all terminals are tight.

3. Evaluator

3.1 Examine evaluator and mountings.

3.2 Check all terminals are tight.

3.3 Check wiring and terminations.

3.4 Measure the DC evaluator supply voltage at the bus bar checking that it is 60V (Limits 55V to 65V).

3.5 Measure the DC stabilised supply on the SIPL card between the 0v and 20v jacks checking that it is 20V (limits 19V to 21V).

3.6 Measure using a meter the voltages on the BUPL card with the +ve lead of the meter in jacks 1a, 1b, 2a and 2b in turn and the –ve lead of the meter connected to the 0v jack on the SIPL card checking that it is 5V DC (limits 4.5V to 5.5V).

3.7 Observe that the ‘FM’ (green) LED on the SIPL card is lit if the axle counter section is clear; conversely confirm the ‘BM’ (red) LED is lit if the section is occupied.

3.8 Where a meter is provided on the battery charger check that the battery charging rate is approximately 200mA.

SERVICE B

Possession of the system shall be taken before undertaking any work. Check that the section TPR links are disconnected before work is started.

4. Rail Contacts

4.1 Check torque settings of fixings NR/SMS/PartZ/Z03 (Train Detection - Reference Values).

4.2 Single Rail Contacts Heads (SK11) Only:

a) Measure the distance between the count heads. Compare the distance with the last recorded.

4.3 If the distance has increased due to rail creep it shall be reported as corrective maintenance.

5. Lineside Junction Box – Type EAK (only)

5.1 Remove and examine cover, interior and connections. Do not remove cover if it is raining.

5.2 Check all terminals are tight.

5.3 Measure using a meter the voltages in Table 1:

Source	Meter +ve	Meter –ve	Volts	Limits
DC Supply	AL3/6	AL3/5	60V	55V to 65V
DC Stabilised	UG+	UG-	50V	48V to 54V
Signal Generator	AL1/3	AL2/2	75V	>75V
Channel 1 SK1	AL4/3	AL4/4	500mV	400mV to 600mV
Channel 1 SK2	AL4/1	AL4/2	500mV	400mV to 600mV

Table 1 – EAK Voltages

NOTE: *Adjustment of SK1 voltage can be achieved by R14 and SK2 by R2.*

5.4 Carry out NR/SMS/PartB/042 (Axle Counters Dummy Wheel Test - AzL 70, 70/30, 70/30S).

5.5 Grease fixing studs and replace cover.

5.6 Repeat sections 4 and 5 for each of the other count head(s) in the axle counter section.

6. Lineside Junction Box - Type EAK30 (only)

6.1 Remove and examine cover, interior, and connections. Do not remove cover if it is raining.

6.2 Check terminals are tight.

6.3 Check both green LEDs are illuminated.

6.4 Measure using the test switch box connected to the socket on the LtAnp board (plug goes in with cable entry at bottom) and a meter the voltages in Table 2:

Item	Meter Connection/ Switch Position	Voltage (DC)
Incoming supply	LTG1 yellow +ve, black –ve	+55V to 115V
Stabilised supply 1	red +ve, black –ve switch position. 3	+22V to +25V
Stabilised supply 2	red +ve, black –ve switch position. 4	+22V to +25V
MESSAB 1	red +ve, black –ve switch position. 10	+55mV to +200mV
MESSAB 2	red +ve, black –ve switch position. 12	+55mV to +200mV
PEGUE 1	red +ve, black –ve switch position. 11	+55mV to +200mV
PEGUE 2	red +ve, black –ve switch position. 13	+55mV to +200mV

Table 2 – LtAnp Board Voltages

6.5 Measure using a meter the transmitter outputs at terms 19/20 for SK1 and 21/22 for SK2:

a) SK1 35V to 49V AC @ 30 to 31.3kHz.

b) SK2 35V to 49V AC @ 27.4 to 28.6kHz.

6.6 Carry out NR/SMS/PartB/042 (Axle Counters Dummy Wheel Test - AzL 70, 70/30, 70/30S).

6.7 Disconnect the test switch box.

6.8 Grease fixing studs and replace cover.

7. Evaluator

7.1 Measure using a meter the voltages on the BUPL card with the +ve lead of the meter in jacks 1a,1b, 2a and 2b in turn and the –ve lead of the meter connected to the 0V jack on the SIPL card:

a) 5V DC (limits 4.5V to 5.5V).

If any BUPL card voltages in this test are below 4.5V with no wheel present, check the correct detection point equipment and line pair.

7.2 Adjust the BUPL card voltages (if necessary) by the top potentiometer on the ANP card for 1/2a and on the bottom potentiometer for 1/2b.

7.3 Check on the SIPL card that the FM (green) LED is illuminated. Using the test switch unit connected to test points 1a and 1b on the BUPL card and 0V on the SIPL card count in 10 axles.

7.4 Observe on the SIPL card that the ‘FM’ (green) LED is extinguished and the ‘BM’ (red) LED is illuminated and the TSR relay de-energises as soon as the first axle is counted in.

7.5 Observe on the FRMKTR card that the ‘EIN’ LED is illuminated and on the ZIANZG card ‘AUS’ LED is extinguished.

7.6 Change the connections on the test switch unit to test points 2a and 2b on the BUPL card leaving the other lead in the 0v on the SIPL card and count out 10 axles.

7.7 Observe on the ZIANZG card the ‘AUS’ LED becomes illuminated and on the FRMKTR card the ‘EIN’ LED is extinguished after the first axle is counted out.

7.8 Check the TSR relay remains de-energised and on the SIPL card the ‘BM’ (red) LED remains illuminated until the last axle is counted out.

7.9 When this has been achieved observe that on the SIPL card the ‘FM’ (green) LED illuminates as the ‘BM’ (red) LED extinguishes and the TSR relay energises.

7.10 If an oscilloscope is available check the interrogator signal on the BUPL card between the 3rd yellow jack (Abfr) and the 0V jack on the SIPL card. The signal appears as a square wave 10V to 12V amplitude with an equal mark-space ratio. The frequency is approx.1850Hz.

7.11 With a test lead (fitted with 4mm plugs at each end) connect jack 1a on the BUPL card to 0V jack on the SIPL card. Operate the reset plunger and observe that the system does not clear.

7.12 Remove the test strap and observe the system remains failed. Operate the plunger again and check the system clears. Repeat the test using the jacks 1b,2a and 2b on the BUPL card in turn.

7.13 Check the operation of the count indicator card (ZIANZG) by shorting together the test terminals. This causes all the segment displays to light (i.e. 888 is indicated).

7.14 Connect the counting test unit to jacks 1a and 1b on the BUPL card and the 0v jack on the SIPL card. Observe that the counter is reset, and the count is clear. Count in one axle and observe the following:

a) The TSR relay drops and the TZR relay picks.

b) On the SIPL card the green LED is extinguished, and the red LED is lit.

c) On the ZIANZG card LED's G1 and G3 are extinguished.

d) The total count shows 1.

7.15 Count in a further 9 axles and check the total count shows 10.

7.16 Transfer the test unit plugs to jacks 2a and 2b on the BUPL card leaving the other in the 0V jack on the SIPL card. Count out 1axle and observe the following:

a) The total count shows 9.

b) On the ZIANZG card LED G1 is illuminated.

7.17 Count out a further 9 axles and observe the following:

a) The total count is zero (display blank).

b) On the ZIANZG card all 3 LED's are lit.

c) On the SIPL card the green LED is lit, and the red LED is extinguished.

d) The TZR relay drops and the TSR relay picks.

e) The green 'Section Clear' indicator at the top of the rack is illuminated.

7.18 With the counter at zero briefly remove and replace the SVA card, observe the following:

a) The counter remains in a failed state and does not attempt to clear.

b) LED G12 on the UMO card is lit.

7.19 Operate the reset plunger and check the following:

a) The counter clears.

b) LED G12 on the UMO card is extinguished.

7.20 With the evaluator reset and showing clear disconnect the 110V supply to the BAUCH PSU, observe the system stays clear. Wait for two minutes and check the DC feed to the evaluator rack does not drop below 60V.

7.21 Reconnect the 110V supply and check that the DC feed to the evaluator rack rises and the system stays clear.

7.22 Check that all the covers are replaced on the front and back of the evaluator rack, locks are replaced on the reset buttons and the TPR links are restored.

7.23 After the axle counter is restored to the Signaller, if practicable observe the correct operation of the equipment with the passage of a train.

END

Includes:	AzL70/30 with EAK30 Lineside Junction Box and AzL70/30 Evaluator AzL70/30S with EAK30 Lineside Junction Box and AzL70/30S Evaluator
Excludes:	All other types of Axle Counter

GENERAL

Make sure that metallic objects are kept away from the rail contacts as they can cause a false count.

Always take possession of the axle counter before adjusting the rail contacts.

If you have to reset the axle-counter, you shall follow the rules in NR/SMS/PartB/Test/030 (AzL Axle Counters: Isolate, Reset & Restore Procedures).

All measurements shall be recorded on the record card.

Always complete the tests on the lineside equipment before carrying out adjustments to the evaluator.

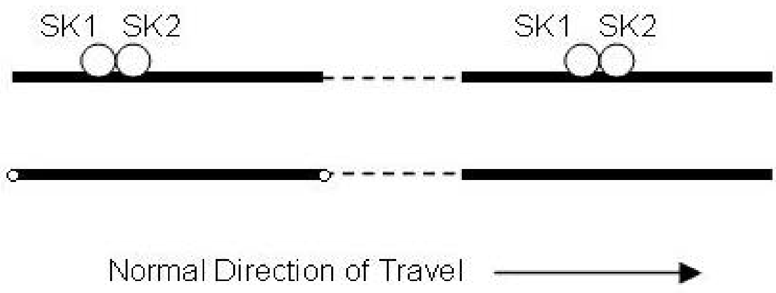

Figure 1 – Typical Layout of Double Rail Contact type (SK30 Heads)

SERVICE A

1. Rail Contacts

1.1 Examine the count heads, rail insulations and bolts. The Tx head shall not touch the rail head. If a head or fixing is loose, check alignment NR/SMS/PartB/Test/042 (Axle Counters Dummy Wheel Test - AzL 70, 70/30, 70/30S) and tighten bolts NR/SMS/PartZ/Z03 (Train Detection - Reference Values).

1.2 Examine all tail cables, connections, and clamps.

1.3 Check the protection plates and flux plates (if fitted) are tight.

2. Lineside Junction Box

2.1 Remove and examine cover, interior and connections. Do not remove cover if it is raining.

2.2 Check terminals are tight.

2.3 Check both green LEDs are illuminated (flashing on 70/30S).

2.4 Using a test switch box connected to the socket on the LtAnp board (plug goes in with cable entry at bottom) and a meter, measure and record the following voltages:

With the meter connected to LTG1 (yellow +Ve, black –Ve):

a) Incoming supply +55V to 115V DC.

With the meter connected to the switch position terminals (red +Ve, black –Ve) measure and record:

b) Stabilised supply 1 (switch pos. 3) +22V to +25V DC.

c) Stabilised supply 2 (switch pos. 4) +22V to +25V DC.

d) MESSAB 1 (switch pos.10) +55mV to +1000mV DC.

e) MESSAB 2 (switch pos.12) +55mV to +1000mV DC.

f) PEGUE 1 (switch pos.11) +55mV to +1000mV DC.

g) PEGUE 2 (switch pos.13) +55mV to +1000mV DC.

2.5 Measure and record using a meter the transmitter outputs at terms 19/20 for SK1 and 21/22 for SK2:

a) SK1 35 – 49V AC @ 30kHz.

b) SK2 35 – 49V AC @ 29kHz.

2.6 Disconnect the test switch box, grease fixing studs, and replace cover.

3. Evaluator

3.1 Examine evaluator and mountings.

3.2 Check all terminals are tight.

3.3 Check wiring and terminations.

3.4 Measure and record the DC evaluator supply voltage at the bus bar check that the voltage is 60V (Limits 54V to 72V).

3.5 Measure and record the DC stabilised supply on the SIPL card between the 0V and 20V jacks check that the voltage is 20V (limits 19V to 21V).

3.6 Measure and record using a meter the voltages on the BUPL card with the +Ve lead of the meter in jacks 1a,1b,2a,2b in turn and the –Ve lead of the meter connected to the 0V jack on the SIPL card, check that the voltage is 5V DC (limits 4.7V to 7V.

3.7 Check that the G1 (green) LED on the SIPL card is illuminated if the axle counter section is clear; conversely check the G2 LED (red) is illuminated if the section is occupied.

3.8 Check (where a meter is provided on the battery charger) that the battery charging rate is correct for the number of detection points being fed.

SERVICE B

Possession of the system is essential. Check that the section TPR links are disconnected before work is started.

4. Rail Contacts

4.1 Check torque settings of fixings NR/SMS/PartZ/Z03 (Train Detection - Reference Values).

5. Lineside Junction Box

5.1 Remove and examine cover, interior, and connections. Do not remove cover if it is raining.

5.2 Check all terminals are tight.

5.3 Measure and record using the lineside test switch box and a meter the incoming supply to terminals: LTG1 (yellow +Ve, black -Ve) check the voltage is +55V to +115V DC.

5.4 Measure and record the stabilised supplies (switch positions 3 and 4 on the lineside test switch box), check the voltage is +22V to +25V DC.

5.5 Measure and record the transmitter outputs at terms 19/20 for SK1 and 21/22 for SK2

a) SK1 35 – 49V AC @ 30kHz.

b) SK2 35 – 49V AC @ 29kHz.

5.6 Carry out NR/SMS/PartB/Test/042 (Axle Counters Dummy Wheel Test - AzL 70, 70/30, 70/30S).

5.7 Count Head Sites with Local Power Supply Only: Check that the evaluator is showing clear; disconnect the 110V supply to the BAUCH PSU and check that the system remains clear.

5.8 Wait approximately 2 minutes and measure the DC supply to the junction box. Check the reading is >60V.

5.9 Reconnect the 110V supply and check the DC supply to the junction box rises and the evaluator remains clear.

5.10 Grease fixing studs and replace cover.

5.11 Repeat steps 4 and 5 for the other count head(s) in the axle counter section.

NOTE: *The evaluator logic will now be out of step.*

6. Evaluator Voltages/Waveforms

6.1 Check that the counter is at zero and measure using a meter the DC voltage with the +Ve lead of the meter to the small yellow jacks on the BUPL card and the –Ve lead of the meter to the 0V jack on the SIPL card measure and record:

a) 2nd terminal (+7.5V) Limits +7V to +9V.

b) 4th terminal (Rel.F) Limits -13.5V to -16.5V.

c) 5th terminal (GR.2) Limits +19V to +21V.

d) 6th terminal (+5v) Limits +4.5V to +5.5V.

6.2 Measure and record using a meter the voltages on the BUPL card with the +ve lead of the meter in jacks 1a,1b, 2a,2b in turn and the –ve lead of the meter connected to the 0V jack on the SIPL card.

a) 5V DC (limits 4.7V to 7V)

Sections with 3 counting points, also measure 3a, 3b.

If any BUPL card voltages in this test are below 4.7V with no wheel present, check first the detection point equipment and line pair before adjusting the gain on the relevant LTV card.

Depending on the installation, if there are more than two Zp (e.g. one count in Zp and two count out Zp over a set of points) there will be a second LTV-A & DIS card for this Zp, see NR/SMS/Appendix/15 (General Information on the Thales Axle Counter Systems).

6.3 Adjust the BUPL card voltages (if necessary) by the S1 potentiometer on the LTV-E card for 1a/b and on the LTV-A card for 2a/b.

6.4 Check (if an oscilloscope is available) the interrogator signal on the BUPL card between the 3rd yellow jack (Abfr) and the 0v jack on the SIPL card.

The signal should appear as a square wave 10V to 12V pk-pk amplitude with a equal mark/space ratio. The frequency is approx.1850Hz.

7. Closed Loop Supervision Check

7.1 With a test lead, (fitted with 4mm plugs at each end) connect jack 1a on the BUPL card to 0V jack on the SIPL card.

7.2 Operate the reset plunger and observe that the system does not clear.

7.3 Check that the LED G2 on the DIS(1) card is illuminated.

7.4 Remove the test strap and observe the system remains failed. Operate the plunger again and check the system clears. Repeat the test using the jacks 1b, 2a, 2b on the BUPL card in turn noting the results are as follows:

a) Strap to 1b lights LED G1 on card DIS(1).

b) Strap to 2a lights LED G2 on card DIS(2).

c) Strap to 2b lights LED G1 on card DIS(2).

NOTE: *3a & 3b jacks if an extra LTV-A/DIS cards are fitted.*

8. Count Indication Card

8.1 If provided, check the operation of the count indicator card (ZIANZG) by shorting together the test terminals. This causes all the segment displays to light (i.e. 888 is indicated).

9. Evaluator Counting Check

The tasks in 9.1 to 9.4 require the use of a counting test unit, if this is not available tasks 9.5 to 9.8 shall be used (these require two test leads with 4mm plugs on each end). A ZIANZG card (if not fitted) is required for counting checking.

9.1 Connect the counting test unit to jacks 1a and 1b on the BUPL card and the 0V jack on the SIPL card. Observe that the counter is reset, and the count is clear. Count in one axle and observe the following:

a) The TSR relay drops and the TZR relay picks.

b) On the SIPL card the green LED is extinguished, and the red LED is illuminated.

c) The count direction indicator (LED G10 on the GRDFR card) lights after a short time.

d) On the ZIANZG card LEDs G1 and G3 are extinguished.

e) The total count shows 1.

9.2 Count in a further 9 axles and check the total count shows 10.

9.3 Transfer the test unit plugs to jacks 2a and 2b on the BUPL card leaving the other in the 0V jack on the SIPL card. Count out 1 axle and observe the following:

a) The total count shows 9.

b) On the GRDFR card LED G10 is extinguished.

c) On the ZIANZG card LED G1 is illuminated.

9.4 Count out a further 9 axles and observe the following:

a) The total count is zero (display blank).

b) On the ZIANZG card all 3 LEDs are illuminated.

c) On the SIPL card the green LED is illuminated, and the red LED is extinguished.

d) The TZR relay drops and the TSR relay picks.

e) The green 'Section Clear' indicator on the rack is illuminated.

9.5 Observe that the counter is reset, and the count is clear. Count in one axle by connecting the test leads to the listed plug points on the BUPL card in the following order:

Step	Action
1	Connect 1b to 0V
2	Connect 1a to 0V
3	Remove 1b from 0V
4	Remove 1a from 0V

Table 1 – Plug Points

9.6 Check the following:

a) The TSR relay drops and the TZR relay picks.

b) On the SIPL card the green LED is extinguished, and the red LED is illuminated.

c) The count direction indicator (LED G10 on the GRDFR card) lights after a short time.

d) On the ZIANZG card LEDs G1 and G3 are extinguished.

e) The total count shows 1.

9.7 Count in a further 4 axles using the steps described in 9.5 and check the count indicator in the ZIANZG card shows 5.

9.8 Count out one axle by connecting the test leads to the listed plug points on the BUPL card in the following order:

Step	Action
1	Connect 1a to 0V
2	Connect 1b to 0V
3	Remove 1a from 0V
4	Remove 1b from 0V

Table 2 – Plug Points

9.9 Check the following:

a) The total count shows 4.

b) LED G10 on the GRDFR card is extinguished.

c) LED G1 on the ZIANZG card is illuminated.

9.10 Count out the remaining four axles using the steps described in 9.8 then check the following:

a) The total count is zero (display blank).

b) On the ZIANZG card all 3 LEDs are illuminated.

c) On the SIPL card the green LED is illuminated, and the red LED is extinguished.

d) The TZR relay drops and the TSR relay picks.

e) The green ‘Section Clear’ indicator on the rack is illuminated.

10. Count Direction Memory Check

10.1 Using either the method listed in 9.1 (counting test unit) or 9.5 (test leads) count in 1 axle and wait until LED G10 on the GRDFR card lights.

10.2 Operate the reset plunger and check that the counter cannot be reset.

10.3 Press the small push button (T1) on the GRDFR card and observe that LED G10 extinguishes.

10.4 Operate the reset plunger and check that the counter resets and disconnect the counting test unit or remove the test leads.

11. Power Supply Interruption Check

11.1 With the counter at zero briefly remove and replace the SVA card, observe the following:

a) The counter remains in a failed state and does not attempt to clear.

b) LED G12 on the UMO card is illuminated.

11.2 Operate the GRDFR switch and the reset plunger, check the following:

a) The counter clears.

b) LED G12 on the UMO card is extinguished.

12. Standby Battery Check

12.1 With the evaluator reset and showing clear disconnect the 110V supply to the BAUCH PSU, observe the system stays clear.

12.2 Wait for two minutes and check the DC feed to the evaluator rack does not drop below 60V.

12.3 Reconnect the 110V supply and check that the DC feed voltage to the evaluator rack rises and the system stays clear.

13. Final

13.1 Check that all the covers are replaced on the front and back of the evaluator rack, locks are replaced on the reset buttons and the TPR links are restored.

13.2 Check with the Signaller that the axle counter is restored.

13.3 If practical, observe correct operation of the equipment with the passage of a train(s).

END

Includes:	Thales AzLM
Excludes:	All other Axle Counter types

GENERAL

The Earth bonding shall be visually inspected before commencing any task.

Metallic objects shall be kept away from the counting heads as they can cause a false-count.

One axle counter evaluator (ACE) can have up to 32 detection points, one or more of these detection points can be shared with another evaluator therefore two ACEs can be affected by tests on one rail contact.

The SK30H & SK30K set-up procedure causes the associated sections (s) to become disturbed.

Always take possession of the axle counter before adjusting the count heads.

A tested ESD strap shall be used to prevent damage to PCB's.

Check the configuration of the rail contacts before undertaking any preventative or corrective maintenance and arrange in liaison with the Signaller the necessary possession arrangements. If this cannot be arranged, inform your SM(S) of the situation.

The Signaller is responsible for resetting the axle counter section.

You should complete the tests on the lineside equipment before carrying out adjustments to the evaluator.

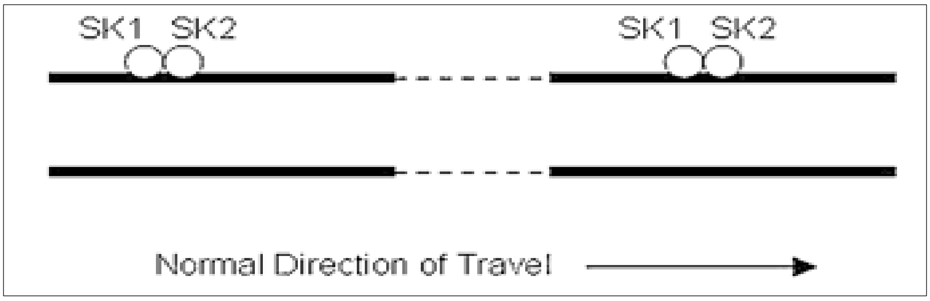

Figure 1 – Typical Layout of Rail Contacts (Type SK30H or SK30K)

Normally increasing Mileage (ARD Axle Counter Reference Direction), see Figure 1.

In the SK30K version the SK1 and SK2 is set via the ARD Plug in the EAK.
The molded TX cable is always connected to SK1 inside the rail sensor if the direction need to be change this can be achieved be adjusting the ARD plug (X600).

Test Equipment

German	English Translation	Part number	Spec
Prüfguppe bestehend aus: Prüfkoffer Messadapter mit diagno-sestecker Digitalvoltmeter	Test Unit consisting of: Test Case Test adapter with diagnostic plug Digital voltmeter	19982 28201	 0.00V to 300V ac/dc
Absenklehre	Dummy wheel	3JA 84532 AAAA	

Table 1 – Test Equipment Part Numbers

The dummy wheel 3JA 84532 AAAA is suitable for all rail contacts, Sk30, Sk30H and Sk30K.

The former dummy wheel 19982 3100x is **NOT** suitable for Sk30K rail contacts.

SERVICE A

1. Diagnostic System

This can be done either at the ACE or remotely.

1.1 Perform a diagnostic download from the system.

A download of the last 24 hours indicates if any other tests are necessary, particularly any data line quality tests.

1.2 Report any fault messages or alarms:

Drift warnings recorded by diagnostics can indicate movement of the rail contact.

1.3 Store the downloaded data separately from the computer. This can be done using an authorised NR memory stick or a CD / DVD. The files and device shall be suitably tagged / labelled and kept for a minimum of five years.

SERVICE B

2. Diagnostic System

This can be done either at the ACE or remotely.

2.1 Perform a diagnostic download on the system.

A download of the last 24 hours indicates if any other tests are necessary, particularly any data line quality tests.

2.2 Report any fault messages or alarms:

Drift warnings recorded by diagnostics can indicate movement of the rail contact.

2.3 Store the downloaded data separately from the computer. This can be done using an authorised NR memory stick or a CD / DVD. The files and device shall be suitably tagged / labelled and kept for a minimum of five years.

2.4 If no train has passed over each detection point during the previous 365 days. Carry out NR/SMS/PartB/Test/031 (Thales Axle Counter Reference Direction Function Test).

The rest of this service need not be completed if the requirements in Section 2 have been successfully completed. If the requirements have not been met then you shall continue with the remaining steps of this service.

3. Rail Contacts SK30H (if fitted)

3.1 Examine the rail contacts, rail insulations, mounting brackets and bolts for security and damage.

The TX head shall not touch the railhead.

If a head or fixing is loose, check the alignment, see NR/SMS/PartB/Test/045 (Thales Axle Counters Dummy Wheel Test (Azlm)) and tighten bolts, see torque values in NR/SMS/PartZ/Z03 (Train Detection – Reference Values).

Drift warnings recorded by diagnostics can be an indication of movement, see NR/SMS/PartB/Test/045 (Thales Axle Counters Dummy Wheel Test (Azlm)) for details of how to set up and adjust the count heads if drift warnings are received.

3.2 Examine all tail cables, connections, rail clamps (if fitted), and brackets for security and damage.

3.3 Check that the cables are clear of any heavy obstructions and protection arrangements are sufficient.

3.4 Check the Pirelli Python' shall be used to protect the cable from the rail contacts to the EAK.

3.5 Check the bung is fitted between the Pirelli Python and cable.

3.6 Check that the labelling on the cables is legible, secure, and intact.

3.7 Check the protection plates and flux plates (if fitted) are tight.

3.8 Check that pads and clips for three sleepers either side of the rail contacts are not damaged or missing.

Damaged or missing items might cause incorrect operation, report defects as corrective maintenance.

3.9 Check the area around the rail contacts (within 2m), check it is free of the following items:

a) P/way defects.

b) New/Scrap rails in the four/six foot or cess.

c) Metallic debris.

d) Traction bonds.

e) Excessive ballast.

Any problems that cannot be rectified shall be reported as corrective maintenance.

3.10 Measure using a approved meter the resistance between the Rx rail contacts and the running rail/M12 bolts. The reading shall be >2MΩ.

If the obtained reading is <2MΩ, the rail mountings will require cleaning or replacing as necessary.

4. Rail Contacts SK30K (if fitted)

4.1 Examine the rail contacts and bolts for security and damage.

If a head is loose, check the alignment, see NR/SMS/PartB/Test/045 (Thales Axle Counters Dummy Wheel Test (Azlm)) and tighten bolts, see torque values in NR/SMS/PartZ/Z03 (Train Detection – Reference Values).

Drift warnings recorded by diagnostics can be an indication of movement, see NR/SMS/PartB/Test/045 (Thales Axle Counters Dummy Wheel Test (Azlm)) for details of how to set up and adjust the count heads if drift warnings are received.

4.2 Examine all tail cables, connections, clamps, and brackets for security and damage. Check that the cables are clear of any heavy obstructions and protection arrangements are sufficient.

4.3 Check the 'Pirelli Python' shall be used to protect the cable from the rail contacts to the EAK.

4.4 Check that the labelling on the cables is legible, secure, and intact.

4.5 Check the protection plates and flux plates (if fitted) are tight.

4.6 Check that pads and clips for three sleepers either side of the rail contacts are not damaged or missing.

Damaged or missing items might cause incorrect operation, report defects as corrective maintenance. If the head is mounted over the sleeper this pad needs to be checked as well.

4.7 Check the area around the rail contacts (within 2m), check it is free of the following items:

a) P/way defects.

b) New/Scrap rails in the four/six foot or cess.

c) Metallic debris.

d) Traction bonds.

e) Excessive ballast

Any problems that cannot be rectified shall be reported to your SM(S).

5. Lineside Junction Box (EAK)

5.1 Examine the following items:

a) Clear Vegetation.

b) Security of the cover.

c) Earth bonding. If necessary, check against the signalling bonding plan.

d) Cable entries, glands, and ties. Unused cable entry points shall have blanking plugs fitted.

e) Cables connections, clamps brackets and protection. 'Pirelli Python' shall be used to protect the cable from the EAK to the rail contacts.

f) EAK identification.

5.2 Check all cables to and from the EAK are undamaged and clear of any heavy obstructions. E.G. new/scrap rails lying across the cable.

6. Axle Counter Evaluator (ACE)

6.1 Check the ACE diagnostics for potential failures or irregularities.

A 24 hour history download will determine if any other tests are necessary, particularly any data line quality tests.

6.2 Check the following for security and signs of damage:

a) PDCU and terminals.

b) DC/DC converter and terminals.

6.3 The ACE cabinet doors shall be left open (if fitted).

PT – PERIODIC TASK

7. Rail Contact Clamp (if fitted)

7.1 Check and examine the clamp is undamaged, correctly fitted and secure.

7.2 Visually check the “norlock” washers are fitted.

If the clamp is found to be loose the “Norlock” washers are possibly incorrectly installed.

When these are fitted correctly installed the chamfered faces face towards each other as shown in Figure 2.

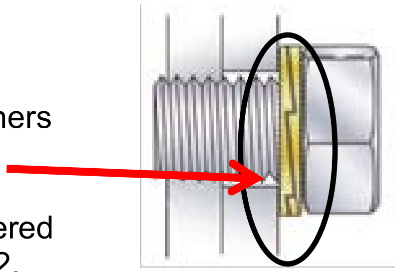

Figure 2

END

Includes:	Siemens AzS ZPD 43 trackside connection box DEK43 double wheel detector
Exclude:	Siemens AzS ZP43 V trackside connection box (see NR/SMS/PartC/AX29), ACE equipment and all other types of wheel detectors

GENERAL

Possession of the relevant track sections of the axle counter shall be taken before adjusting the connection box test levels.

A potential miscount or disturbance to the associated track sections could occur.

Keep switched on mobile phones and metallic objects away from the counting heads whilst undertaking maintenance as they can cause false counts/readings.

If you have to reset the axle counter, follow the appropriate resetting procedure with the Signaller.

More information on the outdoor equipment for Siemens axle counters can be found in NR/SMS/Part/Appendix/01.

SERVICE A

1. Double Wheel Detector (DEK 43)

1.1 Examine the wheel detector count heads, reduction plates and bolts for security and damage.

Reduction plates are fitted both sides of the rail for all types of flat bottom rail.

Only one reduction plate is fitted the receiver side for all types of bull head rail.

1.2 Check that the M12 securing nuts are tight by using the relevant torque wrench tool.

Item	Socket Side	Torque
Wheel detectors	19mm	40Nm to 50Nm

1.3 Check the area around the rail contacts (within 2m) is free of the following items:

a) P/way defects.

b) New/Scrap rails in the four/six foot or cess.

c) Metallic debris.

d) Traction bonds.

e) Excessive ballast.

Report any problems that cannot be rectified.

1.4 Examine all tail cables (protective flexible tubing), connections and clamps for security and damage.

1.5 If practical, observe the passage of a train across the wheel detector and report any excessive deflection in the rail as corrective maintenance.

Excessive deflection in the rail at the point where the wheel detector is fixed to the rail can cause damage to the wheel detector.

SERVICE B

2. Trackside Connection Box

The cover of the trackside connection box shall not be removed during wet conditions unless an alternative suitable cover is available.

Possession of the relevant track sections of the axle counter shall be taken before taking any reading and adjusting the connection box test levels.

If any values are found to be out of tolerance, there might be a fault. This shall be investigated and rectified before any adjustments are carried out.

2.1 Check the area around the trackside connection box is clear of excessive foliage or obstructions.

2.2 Check that the labelling on the trackside connection box is legible, secure, and intact.

2.3 Remove the trackside connection box cover and examine the interior and connections for damage or signs of moisture ingress. Rectify or report.

2.4 Check that all terminals and cards are undamaged and secure.

2.5 Check that both LED's labelled as LED3 are flashing and that no other LED's are illuminated or flashing.

2.6 Using a Fluke (compatible with TPWS) capable of measuring true RMS voltage and frequency, measure the readings at test points specified on the record card NR/SMS/PartR/AX28/RC/01.

If the readings are outside range in 2.9 to 2.11, calibration is required. (See Appendix A).

Any adjustment at the ZP43 shall be followed by adjustment at the Axle Counter Evaluator.

One wheel detector can affect more than one section.

2.7 Measure the incoming DC voltage.

Name	Terminals	Value	Range
Supply voltage	NS + & -	60V DC	30V to 72V

2.8 Measure the AC voltage.

Name	Terminals	Value	Range
Output voltage	NS + & -	Min 1.0V AC	0.48V to 1.8V

2.9 Set the meter for AC voltage and frequency, measure TX 1 & TX 2.

Name	Terminals	Value	Range
Frequency TX 1	6 & 7	43kHz	41.5kHz to 44.5kHz
Frequency TX 2	8 & 9		

2.10 Set the meter for mV AC voltage, measure receiver voltage UE1 & UE2.

Name	Terminals	Range	Comment
Receiver voltage	1 & 2	60mV to 150mV	For very small rail profiles, up to 200mV
Receiver voltage	3 & 4		

2.11 Replace the desiccant bag, replace the cover.

APPENDIX A - ZPD 43 Calibration Procedure

1. Make arrangements with the Signaller for possession of the relevant axle counter sections.

   One wheel detector can affect more than one section.

2. Check that DEK43 is idle and that there are no wheels or other metallic objects in its proximity.

3. Check that switch S1 is set to "FR".

4. Press the T3 and T4 "KAL" buttons at the same time and hold until the L4 LED for each channel lights up, then release both buttons.

   The L3 LEDs will illuminate immediately.

5. After a few seconds the L4 LEDs extinguish, and the L3 LEDs start to flash.

   This indicates that calibration has been completed.

6. Conduct Steps 2.6 to 2.11 above.

7. A delay of 10 seconds is required before attempting re-calibration, if the LED display in Clause 5 indicates that calibration was not successful.

8. If any adjustments are made at the ZP43 wheel detection equipment the VESBA card values for the effected sections at the Axle Counter Evaluator shall be checked

END

Includes:	Siemens AzS ZP43 V trackside connection box, DEK43 double wheel detector
Exclude:	Siemens AzS ZPD 43 trackside connection box (see NR/SMS/PartC/AX28), ACE equipment

GENERAL

Possession of the relevant track sections of the axle counter shall be taken before adjusting the connection box test levels.

A potential miscount or disturbance to the associated track sections could occur.

Keep switched on mobile phones and metallic objects away from the counting heads whilst undertaking maintenance as they can cause false counts/readings.

If you have to reset the axle counter, follow the appropriate resetting procedure with the Signaller.

More information on the outdoor equipment for Siemens axle counters can be found in NR/SMS/Part/Appendix/01.

SERVICE A

1. Double Wheel Detector (DEK 43)

1.1 Examine the wheel detector count heads, reduction plates and bolts for security and damage.

Reduction plates are fitted both sides of the rail for all types of flat bottom rail.

Only one reduction plate is fitted the receiver side for all types of bull head rail.

1.2 Check that the M12 securing nuts are tight by using the relevant torque wrench tool.

Item	Socket Side	Torque
Wheel detectors	19mm	40Nm to 50Nm

1.3 Check the area around the rail contacts (within 2m) is free of the following items:

a) P/way defects.

b) New/Scrap rails in the four/six foot or cess.

c) Metallic debris.

d) Traction bonds.

e) Excessive ballast.

Report any problems that cannot be rectified.

1.4 Examine all tail cables (protective flexible tubing), connections, and clamps for security and damage.

1.5 If practical, observe the passage of a train across the wheel detector and report any excessive deflection in the rail as corrective maintenance.

Excessive deflection in the rail at the point where the wheel detector is fixed to the rail can cause damage to the wheel detector.

SERVICE B

2. Trackside Connection Box

The cover of the trackside connection box shall not be removed during wet conditions unless an alternative suitable cover is available

Possession of the relevant track sections of the axle counter shall be taken before adjusting the connection box test levels.

If any values are found to be out of tolerance, there might be a fault. This shall be investigated and rectified before any adjustments are carried out.

2.1 Check the area around the trackside connection box is clear of excessive foliage or obstructions. Rectify or report as corrective maintenance.

2.2 Check that the labelling on the trackside connection box is legible, secure and intact.

2.3 Remove the trackside connection box cover and examine the interior and connections for damage or signs of moisture ingress. Rectify or report.

2.4 Check the cable entries and glands. Unused cable entry points shall have blanking plugs fitted.

2.5 Check that all terminals and boards are undamaged and secure.

3. Setting up and adjustment of ZP43 V wheel detector equipment

3.1 Both switches on the band-pass filter board shall be set to on. See Figure 1.

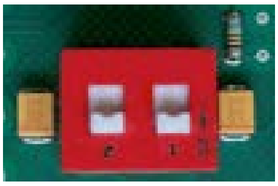

Figure 1

All measurements and any adjustments made shall be recorded on the record card.

3.2 Details of the PEGA test box can be found in NR/SMS/Part/Appendix/01.

If the readings are outside range, adjust as required.

Any adjustment at the ZP43 shall be followed by adjustment at the Axle Counter Evaluator.

3.3 Check that there are no wheels or other metallic objects in the proximity of the wheel detectors.

3.4 Set the switch on the ZP43 V adapter to ZP43E/M and connect it to the PEGA 1211 test box.

3.5 Insert the ZP43 V adapter into slot 2 of the trackside connection box.

3.6 Turn on the PEGA 1211 test box and select operating mode ZP 43 with the mode button and confirm with the OK button.

3.7 Select all further test options using the arrows and the OK button.

3.8 Select U60 on the test box and measure the incoming DC voltage.

Name	Function	Value	Range
Supply voltage	U60	60V DC	30V to 72V

3.9 Select U24 on the test box and measure the operating DC voltage.

Name	Function	Value	Range
Operating voltage	U24	22V DC	21.3V to 22.4V

3.10 Select FS on the test box and measure the frequency.

Name	Function	Value	Range
Wheel detector frequency	FS	43kHz	42.8kHz to 43.2kHz

If the frequency is not within the range adjust the rotary switch on the backplane until the frequency is within range.

3.11 Select UE1 on the test box and measure the receiver voltage 1 then select UE2 and measure the receiver voltage 2.

Name	Function	Range	Comment
Receiver voltage	UE1 & UE2	60mV to 150mV	For vary small rail profiles, up to 200mV

If the receiver voltages are out of range and there is not excessive rail wear the wheel detector might require replacement.

3.12 Select UR1 on the test box and measure the standard voltage.

Name	Function	Value	Range
Standard voltage 1	Ur1	5.5V DC	5.3V to 6.0V

If the voltage is not within the range adjust the potentiometer on the bottom of the generator board until the voltage is within range.

3.13 Select UR2 on the test box and measure the standard voltage.

Name	Function	Value	Range
Standard voltage 2	Ur2	5.5V DC	5.2V to 5.9V

If the voltage is not within the range adjust the potentiometer on the top of the generator board until the voltage is within range.

3.14 Select F1 on the test box and measure the frequency F1

Name	Function	Value	Range
Frequency F1	F1	3.60kHz	3.55kHz to 3.65kHz

If the frequency is not within the range adjust the potentiometer on the bottom of the generator board until the frequency is within range.

3.15 Select F2 on the test box and measure the frequency F2

Name	Function	Value	Range
Frequency F2	F2	6.52kHz	6.42kHz to 6.62kHz

If the frequency is not within the range adjust the potentiometer on the top of the generator board until the frequency is within range.

3.16 Select UL on the test box and measure the output voltage.

Name	Function	Value	Range
Output voltage	UL	Min 1.0V AC	0.48V to 1.8V

3.17 Replace the desiccant bag, replace the cover.

3.18 If any adjustment are made at the ZP43 wheel detection equipment the VESBA card values for the effected sections at the Axle Counter Evaluator shall be checked

END

Includes:	AzSM (E) ACE equipment
Exclude:	DEK43 double wheel detector and trackside connection box (see NR/SMS/AX29)

Possession of the relevant track sections of the axle counter shall be taken before adjusting the connection box test levels.

Make sure switched on mobile phones and metallic objects are kept away from the counting heads whilst undertaking maintenance as they can cause false-counts/readings.

If you have to reset the axle counter, you shall follow the appropriate resetting procedure with the signalman.

More information on the outdoor equipment for Siemens axle counters can be found in NR/SMS/Part/Appendix/01

SERVICE B

1. Evaluator Computer

1.1 Examine evaluator computer and cabinet earthing for damage and security.

1.2 Examine the connection of cable shields to earth for security.

1.3 Check that the fan the operating voltage is present.

The green LED at the front of the fan should be illuminated.

1.4 Check the fan speed is O.K.

The red LED at the front of the fan should be extinguished.

1.5 Check that when the blue button is pressed, the red LED illuminates. Check that the fan fault has been registered on the S&D computer and then clear the appropriate fault from the log.

1.6 Check and if necessary clean or exchange the filter mats.

1.7 Measure using the PEGA 1121 test box in turn, ZAN card values between jacks (with heads fitted):

- Voltage U1 = 3.0 V DC ± 0.10 V DC (socket 5 & 7)
- Frequency f1 = 3.60 kHz ± 0.05 kHz (set at the counting head) (socket 4 & 6)voltage
- Voltage U2 = 3.0 V DC ± 0.10 V DC (sockets 12 &14)

- Frequency f2 = 6.52 kHz ± 0.10 kHz (set at the counting head) (sockets 11 & 13)

All Zero volt jack sockets are common across all ZAN cards. Use a Zero volt jack socket that is not next to the jack socket from which the reading is required.

If any value is found to be out of tolerance, there could be a fault with the cable system or the ZAN card and this should be investigated/rectified before any adjustments are carried out.

1.8 Check that there are no permanently illuminated RED LEDs on any of the Evaluator core components.

End

Includes:	AzS 350U ACE equipment
Exclude:	Siemens AzS ZP 43 V trackside connection box, Siemens AzS ZPD 43 trackside connection box, DEK43 double wheel detector

GENERAL

Possession of the relevant track sections of the axle counter shall be taken before adjusting VESBA card levels.

When inserting and removing test probes from the U, F and 0V test sockets on the VESBA card care shall be taken to avoid contact between the probe and the metal front plate or any other connected test probe.

Take care not to inadvertently press on the red push button on either VAU card, as this will reset the processor, which will place all sections to occupied.

A potential miscount or disturbance to the associated track sections could occur.

Keep switched on mobile phones and metallic objects away from the counting heads whilst undertaking maintenance as they can cause false-counts/readings.

If you have to reset the axle counter, follow the appropriate resetting procedure with the Signaller.

Before measuring or adjusting any VESBA card values the ZP 43 V or ZPD 43 wheel detection equipment values shall be checked (see NR/SMS/PartC/AX28 (Siemens AzS ZP 43 D Wheel Detector Equipment) or NR/SMS/PartC/AX29 (Siemens AzS ZP 43 V Wheel Detector Equipment).

If any value is found to be out of tolerance, there could be a fault with the cable system or the VESBA card.

Investigate this possibility as corrective maintenance before any adjustments are carried out.

More information on the outdoor equipment for Siemens axle counters can be found in NR/SMS/Part/Appendix/01.

SERVICE B

1. Evaluator Computer

1.1 Examine evaluator computer and cabinet earthing for damage and security.

1.2 Examine the surge arrester earthing.

1.3 Using a Fluke (compatible with TPWS) capable of measuring true RMS voltage and frequency, measure in turn the VESBA card values between the test points specified on record card NR/SMS/AX31/RC01.

a) Set meter for DC Voltage measurement (Ur1):

- Meter +ve to U (top right test point).
- Meter -ve to 0V(either in middle row).

Name	Function	Value	Range
Standard voltage	Ur1	3V DC	2.9V to 3.1V

If the voltage is not within range, adjust using the upper potentiometer.

b) Set meter for Frequency measurement (F1):

- Meter +ve to F (top left test point).
- Meter -ve to 0V (either in middle row).

Name	Function	Value	Range
Frequency	F1	3.60kHz	3.55kHz to 3.65kHz

If the frequency is not within range, the ZP 43 V or ZP D 43 wheel detection equipment values shall be checked (see NR/SMS/PartC/AX28 (Siemens AzS ZP 43 D Wheel Detector Equipment) or NR/SMS/PartC/AX29 (Siemens AzS ZP 43 V Wheel Detector Equipment).

c) Set meter for DC Voltage measurement (Ur2):

- Meter +ve to U (bottom right test point).
- Meter -ve to 0V (either in middle row).

Name	Function	Value	Range
Standard voltage	Ur2	3V DC	2.9V to 3.1V

If the voltage is not within range, adjust using the lower potentiometer:

d) Set meter for Frequency measurement (F2):

- Meter +ve to F (bottom left test point).
- Meter -ve to 0V (either in middle row).

Name	Function	Value	Range
Frequency	F2	6.52kHz	6.42kHz to 6.62kHz

If the frequency is not within range, the ZP 43 V or ZP D 43 wheel detection equipment values shall be checked (see NR/SMS/PartC/AX28 (Siemens AzS ZP 43 D Wheel Detector Equipment) or NR/SMS/PartC/AX29 (Siemens AzS ZP 43 V Wheel Detector Equipment).

1.4 Check that there are no permanently illuminated red LEDs on either of the VAU boards.

END

Includes:	Frauscher RSR 123 wheel sensors used in both the Frauscher Advanced Axle Counters and for Supplementary Train Position Axle Counter Sections
Excludes:	All other applications of the RSR 123 wheel sensors

General

More information on the outdoor equipment for Frauscher Advanced Axle Counters can be found in NR/SMS/Appendix/07 (General Information on the Frauscher Advanced Axle Counter).

Information relating to fault finding and fault codes can be found in NR/SMTH/Part10/FF10 (Faulting Guide: Frauscher Advanced Axle Counter).

East Suffolk Line (Only)

On the East Suffolk Line, the supplementary axle counters are uniquely identified on site with the AEB cards fitted with magenta labels (shown circled red in Figure 1).

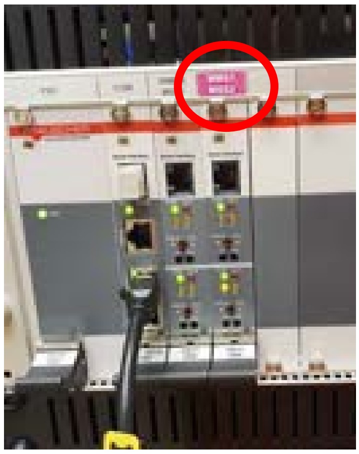

Figure 1 – Magenta Labels

They are configured with Supervisor Track Sections (STS) and Count Head Check (CHC).

The main interlocking control axle counting sections are acting as STS to the train position axle counter sections for the level crossings. The CHC is set to 100.

A record card is available, but completion of a card might not be required if the system being maintained has built data recording capabilities.

PERIODIC TASK 1

1. Alerts and Alarms

1.1 Review all alerts and alarms generated where FAMS is fitted. Arrange for corrective actions to be undertaken and inform your SM(S) of actions which require immediate and 28-day interventions.

1.2 Where FAMS is not available, review the errors generated within FDS and report any issues identified to your SM(S).

PERIODIC TASK 2

2. Remote Occupancy Detection Test

Observe that all sensors in the system have been traversed by a track vehicle or a PB200 testing plate within the last two years.

This can be verified by looking at the FDS or FAMS or equivalent downloads. Where the download does not prove the successful passage of an on-track vehicle, a work order shall be raised to carry out NR/SMS/PartB/Test/037 – Frauscher: RSR123 Wheel Sensor Occupancy Detection Capability Test, for each of the sensors which have not been traversed.

PERIODIC TASK 3

Rail Sensor Height Check

3. Mechanically

3.1 Measure the distance between the wheel sensor top surface and top of rail (distance "A" as shown in Figure 2). This shall be between 40 and 45mm. Adjust height if required. The measurement shall be consistent along the entire length of the wheel sensor.

It is recommended to adjust measurement A between 43 and 45 mm (optimal range).

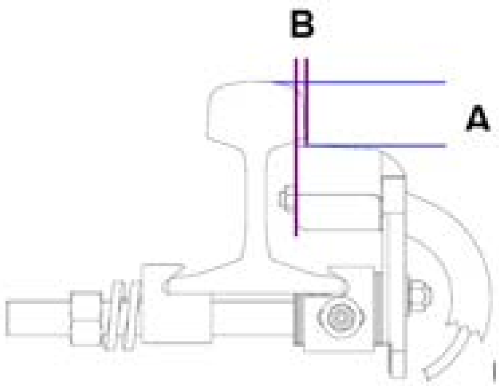

Figure 2 – Maintenance Measurements

NOTE: *Measurement "B" is not checked during maintenance, but only after replacement or installation of a wheel sensor*

3.2 Measure the distance between the wheel sensor inside edge and inside edge of the of rail head (distance "B" as shown in Figure 2). The wheel sensor is positioned slightly below and under the head of the rail. The measurement shall be between 0mm and 6mm. Adjust as required. The measurement shall be consistent along the entire length of the wheel sensor.

If the position of the RSR123 has been changed it shall be electrically re-calibrated using the correct SMS Part B Test.

END

Includes:	Frauscher wheel sensor RSR123
Excludes:	All other types of wheel sensor

A record card is available, but completion of a card might not be required if the system being maintained has built data recording capabilities.

SERVICE B

1. Wheel Sensor Calibration Checks

If RSR123 sensors are used for axle counter applications then carry out one of the methods in Clauses 1.1, 1.2 or 1.3.

1.1 Frauscher Diagnostic System (FDS) or Frauscher Active Monitor System (FAMS)

a) If required, start the web browser on the laptop, enter the IP address and log in.

b) Using the FDS, check the status of the life-signals for both wheel sensor systems are received. Figure 1 shows the life-signal ok (ringed in blue) Figure 2 shows the life-signal failed (ringed in red)

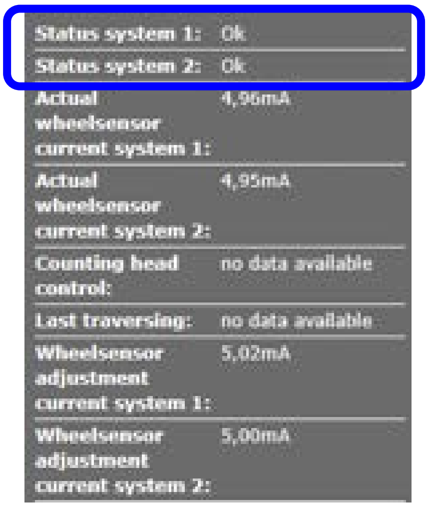

Figure 1 - life-signal ok

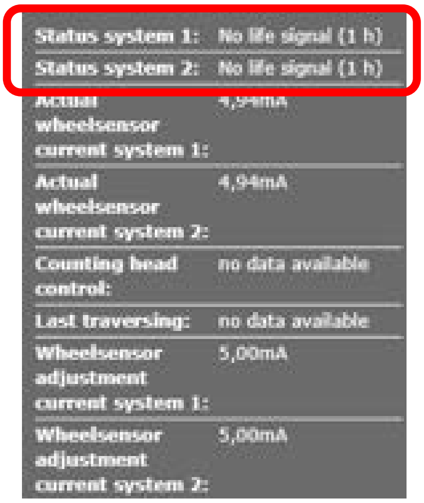

Figure 2 - life-signal failed

c) Check that the readings are within the range.

- *System 1: 5mA ± 5% (4.75mA to 5.25mA).*
- *System 2: 5mA ± 5% (4.75mA to 5.25mA).*

d) If the life-signals are missing and/or the voltages are out of range, this shall be reported to Fault Control.

1.2 Advanced Service Display (ASD)

Use only the correct, isolated and undamaged Advanced Service Display cable. There is no galvanic separation and no protection against overvoltage between the Serial Interface of the AEB and the electronics of the AEB board.

Before checking the sensor system currents with the indoor equipment, confirm that the associated mounted wheel sensor is in an undamped state.

a) Connect the laptop to the AEB by using the serial interface between the AEB and the USB port, with the advanced service display cable.

b) Check if the life-signals for both wheel sensor systems are received.

c) Check the current on the AEB for wheel sensor system 1.

d) Check the current on the AEB for wheel sensor system 2.

e) Check that the readings are within the range:

- *System 1: 5mA ± 5% (4.75mA to 5.25mA).*
- *System 2: 5mA ± 5% (4.75mA to 5.25mA).*

f) If the values are not within the stated range check position of the wheel sensor RSR123 as described in NR/SMS/PartC/AX40 (Frauscher Advanced Axle Counter) - Periodic Task 3.

g) If the position of the RSR123 is correct, adjust wheel sensor as described in NR/SMS/PartB/Test/040 (RSR123 Wheel Sensor Adjustment - associated with AEB Boards).

h) Recheck if the life-signal and currents as per steps b) to e).
i) If the life signal is still missing and/or the currents are out of range, replace the wheel sensor as described in NR/SMTH/Part04/AX40 (Replace a Frauscher wheel sensor RSR123).

1.3 Advanced Evaluation Board (AEB)

a) Plug the multi-meter into the 2mm test sockets on the AEB and check if the life-signals for both wheel sensor systems are received.

NOTE: *The voltage should alternate from 0.5 V for 4 seconds to 0.51 V for 2 seconds. If the voltage is constant at 0.5 V no life-signal is present.*

b) Measure the voltage on the AEB for wheel sensor system 1.

c) Measure the voltage on the AEB for wheel sensor system 2.

d) Check that the readings are within the range:

- *System 1: 500mV ± 5% (475mV to 525mV).*
- *System 2: 500mV ± 5% (475mV to 525mV).*

NOTE: *The measured voltage complies with the wheel sensor system current via a 100 Ω shunt (100 mV therefore complies with 1 mA wheel sensor system current).*

e) If the values are not within the stated range check position of the wheel sensor RSR123 as described NR/SMS/PartC/AX40 (Frauscher Advanced Axle Counter) - Periodic Task 3.

f) If the position of the RSR123 is correct, adjust wheel sensor as described in NR/SMS/PartB/Test/040 (Frauscher : RSR123 Wheel Sensor adjustment – associated with AEB Boards).

g) Recheck if the life-signal and voltages as per steps a) to d).
h) If the life signal is still missing and/or the voltages are out of range, replace the wheel sensor as described in NR/SMTH/Part04/AX40 (Replace a Frauscher wheel sensor RSR123).

PERIODIC TASK 1

2. Mechanical and visual check of wheel sensor RSR123

2.1 Examine the wheel sensor mounting plates and bolts for heavy soiling, security and external damage.

2.2 Check the area around the rail contacts (within 2m) are free of such items as:

- Visible P/way defects.
- Metallic debris.
- New/scrap rails in the four/six foot or cess.
- Traction bonds.
- Excessive ballast.

Any problems that cannot be rectified shall be reported as corrective maintenance.

2.3 Observe exposed tail cables (protection tube), plug couplers and connections for security and damage.

PERIODIC TASK 2

3. Head Sensor Security

There are two variants of the Frauscher Rail Claw, confirm which is fitted before proceeding.

GS02 Rail Claw Only

3.1 Check the rail sensor securing nuts are tightened to correct torque values using an approved torque wrench tool as follows:

a) Figure 3 Allen Screws to 25Nm

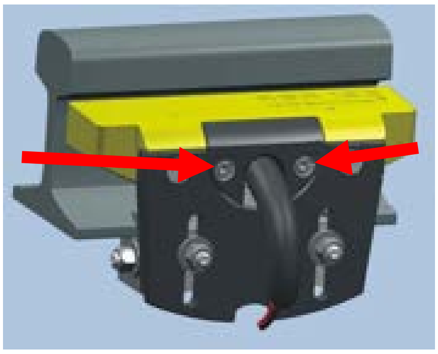

Figure 3 - Allen Screws

b) Figure 4 M10 nuts to 15Nm (Checked during installation/replacement only)

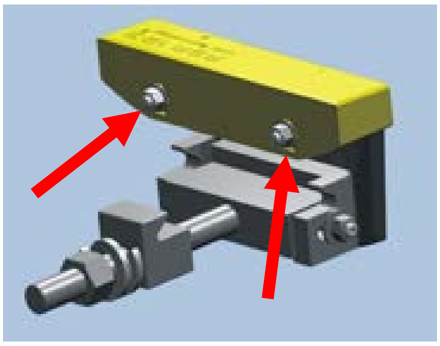

Figure 4 - M10 Nuts

c) Figure 5 M12 nuts to 40Nm.

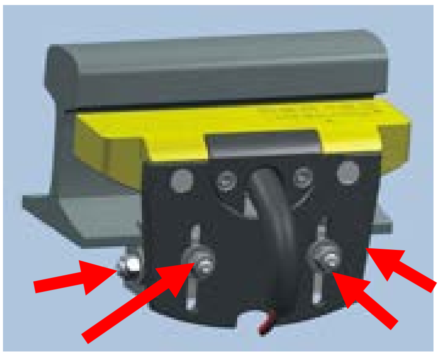

Figure 5 - M12 Nuts

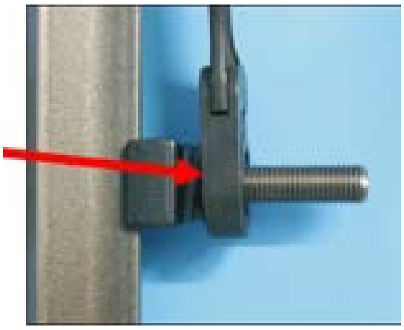
Figure 6 – Rail Claw Nut

d) Figure 6 The Rail claw nut shall be tightened until the ends of the spring washer touch the main body of the washer, at this point the nut shall be tightened a further 360°.



GS04 Rail Claw Only

3.2 The GS04 Rail Claw has GS04 marked in the centre of the mounting plate for identification purposes.

3.3 Check the rail sensor securing nuts are tightened to correct torque values using an approved torque wrench tool see Figure 7 for details.

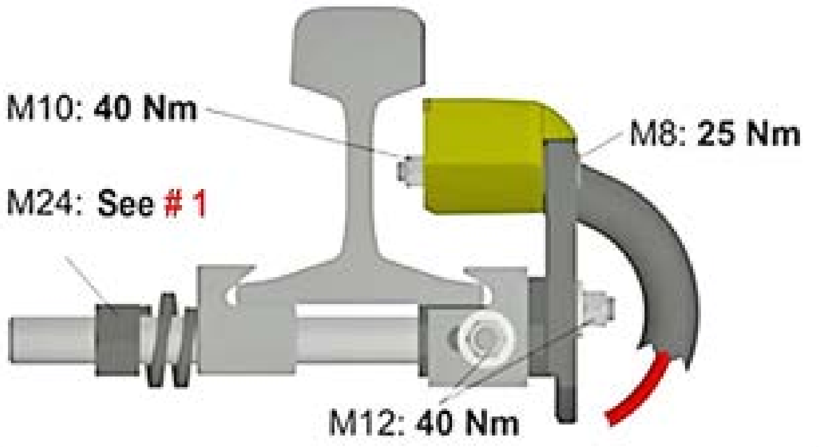


Figure 7 – Rail Claw Torque Values

#1 The rail claw nut shall be tightened until the ends of the spring washer touch the main body of the washer, at this point the nut shall be tightened a further 360°.

END

Includes:	Input / Output Extension Board IO-EXB used for data transmission with DUAL inputs
Excludes:	Input / Output Extension Board configured with QUAD outputs

This check is not necessary if QUAD outputs are used.

This test is required when using the IO-EXB for data transmission.

The responsible designer, who configures the IO-EXB, has to provide information as to whether the check is carried out automatically by the system, or whether the check has to be carried out by the maintenance personnel.

In this case, the designer has to give proper instructions how the check shall be carried out.

SERVICE C

1. Input / Output Extension Board (IO-EXB)

Provide switching states for both of the inputs used as shown in the Table 1.

Input 1	Input 2	Output 1	Output 2
HIGH	HIGH	HIGH	HIGH
LOW	HIGH	LOW	LOW
HIGH	LOW	LOW	LOW
LOW	LOW	LOW	LOW

Table 1 – Input / Output Extension Board (IO-EXB)

Providing of the switching states as described above guarantees that both inputs are operating correctly.

It is also necessary to check each of the two outputs used, to determine whether it is able to enter failsafe state.

END

Includes:	ACM 100 (ACM module and WSD wheel detector)
Excludes:	All other Axle Counter systems

Do not remove the ID-Plug unless faulty or replacing the ACM100 module.

Do not press any buttons on the front of the ACM100 module without permission from the signaller.

Keep switched on mobile phones 3m away from the counting heads whilst undertaking maintenance as they can cause false-counts/readings.

Keep metallic objects at least 20cm away from the counting heads. The movement of metallic objects including tools, steel toe-cap boots and jewellery across the upper surface of the counting heads can cause occupation of the track sections.The wheel detector is very sensitive.

If you have to reset the axle counter, the appropriate resetting procedure with the signaller shall be followed.

All wires of the connecting cable to the wheel detector can be subject to interference voltages. Do not touch live parts. This is particularly to be observed when working on the junction box (attaching wires, performing checks).

SERVICE B

1. Wheel Detector (WSD)

1.1 Examine the WSD, mounting plates and bolts for security and damage.

1.2 Check that the M12 securing nuts are tight (45 Nm) by using the appropriate torque wrench tool with 19mm socket.

1.3 Clean any loose metallic and other deposits from the surface of the WSD.

1.4 Check the area around the rail Wheel Sensor (within 2 m) is free of the following items:

a) P/way defects.
b) New/scrap rails in the four/six foot or cess.
c) Metallic debris.
d) Traction bonds.
e) Ballast in contact with the plastic housing of the wheel sensor.

1.5 Examine all tail cables (protective flexible tubing), connections, and clamps for security and damage. Resecure or replace as required.

1.6 Check that the distance from the top of the rail head and the top surface of the wheel sensor is 45mm (tolerance +0mm/-2mm) using the adjustment gauge as shown in figure 1. If the distance is outside of this tolerance, adjust the height of the wheel sensor to the correct value.

The adjustment gauge shall be placed on the wheel sensor with the green steel plate upper most. Otherwise the track sections might become occupied.

For an accurate measurement, place a straight edge across both the rail head and adjustment gauge.

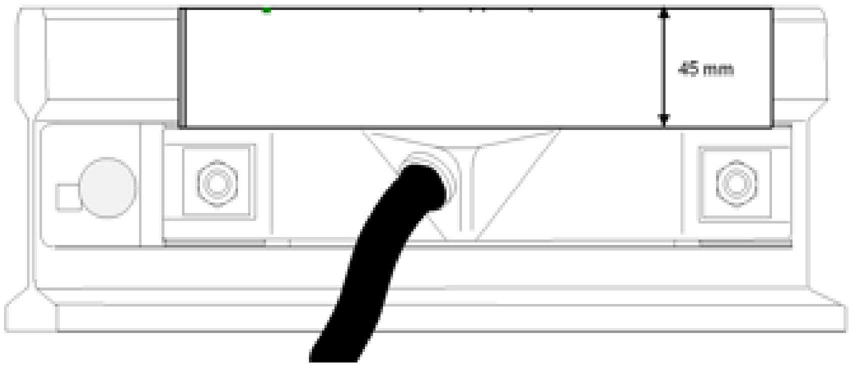

Figure 1 – Gauge position to check the WSD height

1.7 If using a rail clamp rather than rail web mounting, also check the distance from the rail (see figures 2, 3 and 4).

Figure 2 – Too close to the rail

Figure 3 – Too far away from the rail

Figure 4 – Correct position

If the distance is out of this range, adjust the position to the correct distance as shown in Figure 4.

1.8 Recalibrate and test the wheel sensor [Test038]

1.9 If practical, observe the passage of a train across the wheel detector and report any excessive deflection in the rail as corrective maintenance.

Excessive deflection in the rail at the point where the wheel detector is fixed to the rail can cause damage to the wheel detector.

2. ACM Module, PSU, UPS and Ethernet Switch

2.1 Examine the components for damage or signs of moisture ingress. Rectify or report as corrective maintenance.

2.2 Check that all connections to the ACM100 module, PSU, UPS and Ethernet Switch are undamaged and secure.

2.3 Check for RED or flashing LEDs on ACM100, PSU and UPS modules. Refer to NR/SMS/Appendix 13 for LED normal and fault state details. In case of any LED fault indication status, rectify or report as corrective maintenance.

End

Includes:	Siemens - RSE Wheel detector (TETS System Richmond only)
Excludes:	All other types of wheel detector and sensor

Protection / Possession arrangement shall be taken before commencing work on any track sections

System Description

The Siemens Wheel Detector is a switching device which responds to the presence of wheel flanges of passing trains. It is used within the speed control system at Richmond as part of the LUL Trains Entering Terminal Stations system it consists of the following parts:

- A sensing head / tail cable assembly which is mounted to the inside web of one of the rails, known as the RSE Wheel Sensor (Fig 1)
- Disconnection box mounted in the cess, known as the Cable Junction Box.
- An evaluator interface PCB which is installed in the relay room, known as the ARS4.
- A power supply unit.

Fig 1 – RSE Wheel sensor

The rail mounted sensor and its control circuitry are connected via the cable junction box by a single twisted pair, screened cable.

Maintenance equipment

- M13 Ring spanner
- Flat-bladed Screwdriver (large)
- M13 Torque Spanner (range 70-80Nm)
- Adjustable Sliding Set Square
- Multimeter with voltage internal resistance greater than 50Kohms per volt.

SERVICE B

1. RSE Wheel sensor Assembly

1.1 Remove all fire risks, e.g. waste paper, oily rags, etc. from the vicinity of the sensing head and the tail cable.

1.2 Remove any metallic or other conductive debris from the vicinity of the sensing head.

1.3 Check that the sensing head and mountings are clear of the ballast and check that no other obstacles are able to foul the space between the top of the sensing head, and the position of the wheel flanges of passing trains.

1.4 Check that where the tail cable is routed underneath the sensor, that it does / will not get trapped between the sensor and ballast during the passage of traffic.

1.5 Clean the sensing head of dirt and debris particularly any build-up of brake dust or rail swarf with the relevant approved cleaning agent.

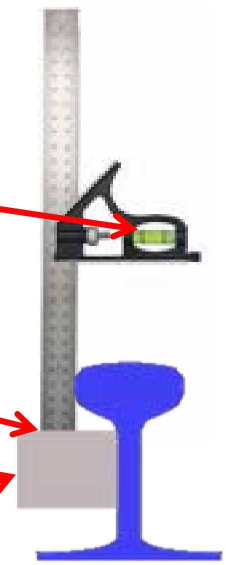
1.6 Examine the sensing head fixings to the rail. Check that they are secure and that there is no evidence of movement/vibration.

1.7 Examine the sensing head for damage (damage can indicate an incorrect height setting of the sensor), Damage, which is assessed as being able to affect the functionality or reliability of the equipment, shall be reported to your SM(S) who shall arrange for the replacement of the sensing head.

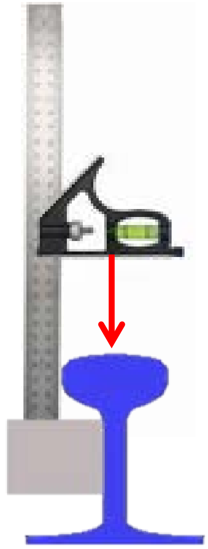
1.8 Check the height setting of the sensing head with the use of an adjustable sliding set square as follows:

> At locations where conductor rails are in use an insulated shield shall be placed over the live rail adjacent to the Sensor head before checking the sensor head height.

- Keeping the bubble level
- Place the end of the rule square down onto the sensing head



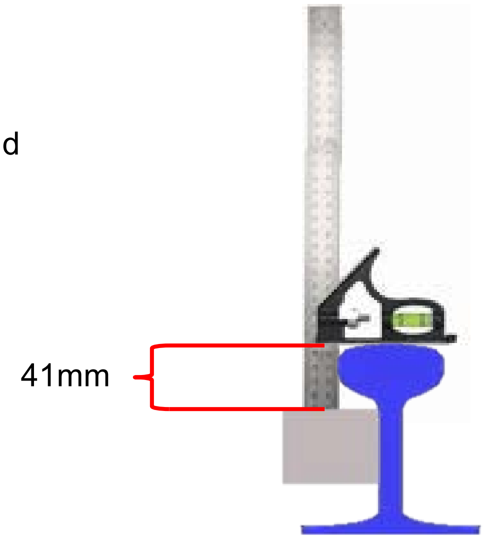
Sensor Head



- Slide the body of the square down onto the rail head.

- Measure the vertical height from the top surface of the sensing head to the top of the rail at both ends of the sensing head

- The sensing head should be positioned parallel to the rail top and the height dimension at either end should be 41mm +/-1mm.



1.9 If the sensor height setting requires adjustment, then this shall be undertaken as follows:

- At the outside web of the rail slacken the two M13 fixing nuts which secure the sensing head to the rail.

- On the sensing head, slacken the two M13 adjusting nuts which secure the sensing head to the circular adjustable cams.

- By using a flat bladed screwdriver into the slots provided on the ends of the adjusting bolts on the sensor, turn the bolts slightly until the sensing head is adjusted to the correct setting.

- If the adjusting bolts (or the fixing bolts) turn continuously in the anti-clockwise direction, without the height setting being changed, then stop.

This means that the bolts are unscrewing from the circular adjusting cams and will eventually come out. To remedy, re-tighten all the bolts .and adjust the sensor height by hand and proceed as follows.

- Tighten all the nuts and recheck the height position at both ends of the sensing head. Adjusting nuts and fixing nuts shall be tightened to a torque of 70-80Nm Where separate locking nuts are used, screw them down by hand and then using a spanner give a further quarter to half turn. Where self-locking nuts are used e.g. Nylocs, or spring/crinkle washers, these shall be replaced with new items when adjustments are made and shall not be used more than once.

1.10 Examine the tail cable and gland to the sensor for general condition and security. Check that the tail cable is routed and secure in order to be clear of the rails and to prevent damage by passing traffic or on-track maintenance machines.

* 1.11 Check the operation of the wheel sensor by placing a metal spanner close to the running edge of the rail above the middle of the sensor head or await the passage of a train over the sensor and check that:

- Either, the current through the sensor measured at the ARS4 board reduces from the undamped value (between 5.5 - 8.0mA) to the damped value (between 0.0 - 1.0mA) and subsequently returns to its previous value upon removal of the switching medium.

- Or, the applicable LED on the ARS4 front panel indicates (by extinguishing / darkening) that the wheel detector has correctly operated.

1.12 Check the condition of the rail at the sensor mounting position for the following:

- Excessive burring of the rail top over onto the running edge of the rail; this can permanently activate the sensor.

- Excessive side wear (max. 15mm) of the running edge, this may allow the wheel flange to pass to the side of the wheel detector and not be detected.

A Permanent Way “053 Gauge” can be used for this purpose

- The condition of the area adjacent to the mounting holes in the rail web for corrosion and cracking.

1.13 Any deficiency shall be reported to the SM(S)

2. Cable Junction Box

2.1 Check the cable junction box for general condition and damage and that all mountings are secure.

2.2 Check that the connecting cables to the junction box are secure and that they are properly supported. Check the security of protective hose cable clips.

2.3 Check the lid fastening and seal arrangement and clean the interior of tl1e junction box. Check the terminations for security and evidence of corrosion and protect if necessary.

2.4 Clean the outside of the cable junction box.

3. ARS 4 Evaluation Unit

The evaluation unit PCB's are static sensitive devices and should be handled accordingly.

3.1 Check the PCB's for general condition and security within the holder. Defects shall be reported to the SM(S) who shall arrange for replacement.

3.2 For each wheel detector controlled by the ARS board measure and record the following checks on the appropriate record card:

- Press the relevant test button (marked T1, T2,T3, T4) and check that the applicable LED (marked L1, L2, L3, L4) on the ARS 4 front panel indicates (by extinguishing/darkening) that the circuitry has tested satisfactorily (see Fig 4b.).

- Press the relevant test button (marked T1, T2, T3, T4) and check the switching of the output voltage (1.5 - 4.5V DC) to the follower relays as the test button is pressed. (See fig 4a).

Channel 1 – Measure the voltage across terminals B2 and B6, then press the test button T1 and measure the voltage across terminals B4 and B6. The voltage seen on the second set of terminals should be same as that on the first set.

Channel 2 - Measure the voltage across terminals Z10 and Z14, then press the test button T2 and measure the voltage across terminals Z12 and Z14. The voltage seen on the second set of terminals should be same as that on the first set.

Channel 3 - Measure the voltage across terminals B18 and B22, then press the test button T3 and measure the voltage across terminals B20 and B22. The voltage seen on the second set of terminals should be same as that on the first set.

Channel 4 - Measure the voltage across terminals Z26 and Z30, then press the test button T4 and measure the voltage across terminals Z28 and Z30. The voltage seen on the second set of terminals should be same as that on the first set.

For details of terminal locations see fig 4a - ARS 4 Terminations.

3.3 Alternatively, if the relevant track circuit can be "dropped', check that the follower relay operates when the relevant test buttons are pressed.

Termination	Points		
B2	Z2		D2
B4	Z4		D4
B6	Z6		D6
B8	Z8		D8
B10	Z10		D10
B12	Z12		D12
B14	Z14		D14
B16	Z16		D16
B18	Z18		D18
B20	Z20		D20
B22	Z22		D22
B24	Z24		D24
B26	Z26		D26
B28	Z28		D28
B30	Z30		D30
B32	Z32		D32

(Termination points are located at the base of the card)

Fig 4a - ARS 4 Terminations

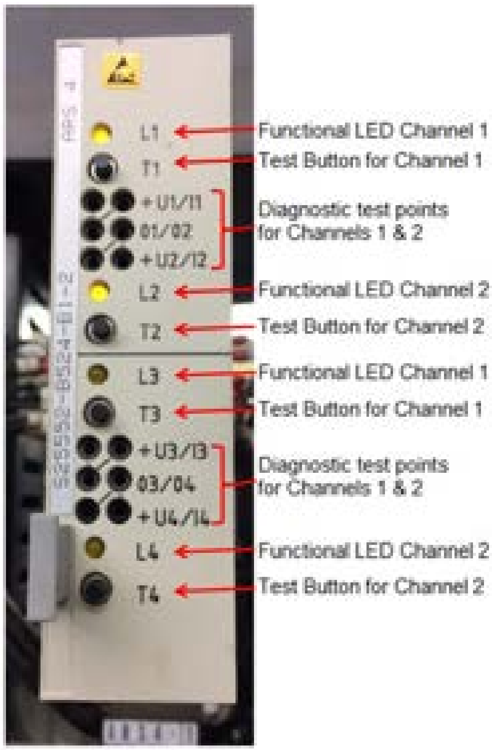


Fig 4b - ARS 4 Front Panel

4. Power Supply

4.1 Dust and examine the power supply unit.

4.2 Examine earth connections checking they are in good working order.

4.3 Examine terminations, clean and protect as necessary.

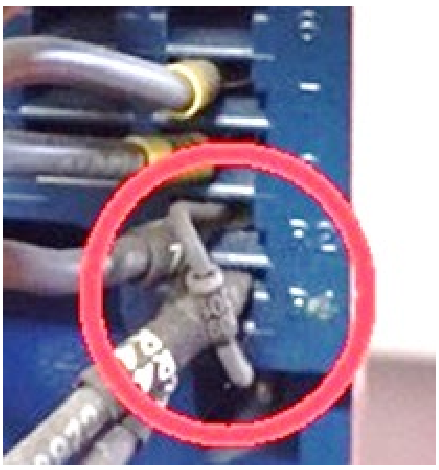
4.4 Examine cable and wiring to the power unit for general condition and for protection along its route.

4.5 Measure the 50VDC (nominal) supply voltage to the evaluation unit (ARS 4).

This should measure between 45-72VDC.

5. Diode

5.1 Check local diagrams to identify any relays fitted with diodes (as shown in the diagram to the right). Visually examine the diode across the interface relay coil to check that it appears to still be connected.



END

Includes:	TASS Balise and Balise Mounting Assembly
Excludes:	Any other type of Balise

A damaged or displaced balise assembly which is affecting the safe passage of trains, or a risk to personnel, shall be removed immediately to a secure location and the Signaller advised.

If the bracket is damaged, then protective gloves shall be worn when removing the item.

Figure 1 - TASS Balise assembly installed using the rapid fixing kit

TASS is an abbreviation for 'Tilt Authorisation and Speed Supervision'. It consists of trainborne equipment and Balises (trackside TASS beacons).

The Balise and Mounting Bracket assembly shall be exchanged for a completely new unit when Balise replacement is required.

Such units shall be assembled in a controlled environment away from the trackside and issued to site as required.

Balises have been manufactured to withstand extreme conditions and the electronics inside are sealed to protect them from the environment, thus improving reliability.

During maintenance visits, if damaged units are found, they are to be removed and returned to the supplier.

Under no circumstances should any type of repair to a Balise and Mounting Bracket assembly be attempted on site.

Replacement of the Mounting Bracket assembly as a component separate from the Balise is permitted if this is necessary to make good any minor damage or to facilitate a change of track fastening type.

There is no need to periodically check the Balise with the Telegram Reading Tool.

A Balise failure affecting the telegram data is identified and protected by the trainborne TASS system and reported by the driver.

SERVICE B

1. Balise Assembly

1.1 Check that the Balise and fastenings are securely positioned.

If the balise is displaced or if fastenings are loose or are becoming loose, report it as corrective maintenance.

1.2 Remove metallic and other debris and combustible material from the proximity of the Balise.

1.3 Remove any ballast that is impacting on the Balise. Especially underneath, to prevent the unit being put under mechanical stress, which can result in cracking or de-lamination?

1.4 Check the 14 character identifier is intact on both the Balise and mounting assembly and that the two identifiers are identical and correct and match the Balise records.

If defaced, illegible or incorrect, report it as corrective maintenance.

1.5 Examine the Balise assembly. If any signs of damage, tampering, or vandalism are visible report it as corrective maintenance

1.6 Examine the Balise connector cover. If missing or any signs of tampering or vandalism report it to your SM(S).

END

Includes:	Ansaldo Eurobalise
Excludes:	TASS Balise and all other Balises

General

There is no requirement to periodically check the Balise with the Telegram Reading Tool if a JRU train download is scheduled. Any issues are identified and recorded by the train borne equipment.

This excludes locally controlled level crossing & Temporary Speed Restriction (TSR) Balises.

This record of failure is also reported via the Radio Block Centre to SAM, as an ERROR.

DAILY SERVICES

1. Messages

1.1 Check SILAM for any Balise "ERROR" messages received from trains during the previous 24 hours or since the last check.

1.2 Where a Balise or Balise group display an ERROR message the actions in Table 1 shall be taken.

Some Balise groups are likely to display ERROR messages routinely due to their positioning in relation to shunting, reversing and terminating moves.

Where this is suspected to be the cause of an ERROR message, inform the SUPERVISOR who shall decide what action is to be taken.

Balise	ERROR	Action
Odometry and Awakening	2 or more messages in any 24-hour period 3 or more failures in any 7-day period 7 or more failures in a 28-day period	Report as a failure of equipment
Text Message Balise Odometry Balise with a Text Message	Single failure to read. *Note: - when a driver fails to receive a message from a Balise he is required to report this failure to the Signaller.*	Inform the Signaller
Stop Balise	A Balise containing stop data is linked to others in the group, should a single Balise fail to be read the train is tripped automatically. If more than one Balise in the group fails, this should be found using the daily service.	The cause of the train being tripped shall be investigated. Inform the Signaller who should report the failure.

Balise	ERROR	Action
Automatic Wheel Diameter Calibration Balise	Packet 4 using M_ERROR to show a “Balise consistency linking” error. (O)	Report as an equipment failure
All Balise Groups	Where errors of more than one Balise group are associated with a particular Engine NID number and all other trains read the Balise correctly	Report the event as an on-board failure to the ICC including details of the location of the Errors, the Engine NID, the Unit or Locomotive Number and the service Headcode.

Table 1 - Balise Group Error Messages

REGULAR TASK

2. JRU download

2.1 Perform a JRU train download for analysis.

SERVICE B

3. Llanbadarn Locally Controlled Level Crossing Balise

3.1 Check with the Balise Programming Tool that each Balise in the group is operating correctly by reading the stored message over the air gap.

END

Includes:	KVB Balise (Contrôle de Vitesse par Balises) Used in Ashford, Kent.
Excludes:	All other types of Balise

GENERAL

Obtain the Signallers permission for work which interferes with the signalling equipment.

Details of the use of the KVB tester can be found in SMS Appendix 23.

SERVICE B

1. REB/Location Case Checks (Switchable Balises Only)

1.1 Check LED indications are correct on both the microprocessor and power supply cards as follows:

a) Green LED on AHT card, normally illuminated, indicates presence of 5V power supply.

b) Green LED on UCS card, normally illuminated, indicates card working correctly.

c) The yellow LED on the UCS card is normally not iluminated unless indicating “presence train “ or initialization under way following a rack re-energisation. In initialization stage is within 30 seconds.

1.2 With the UCS maintenance card connected verify that that no errors are present in the encoder memory record log.

All faults shall be investigated. Details of each fault shall be passed to the SM(S).

Additional information on fault finding can be found in NR/SMTH/Part10/FF26 (Faulting Guide : KVB Balise).

1.3 Erase the “Failure Memory”.

Additional information on the KVB test set can be found in SMS Appendix 23.

2. Trackside

2.1 Check the balise (signal and marker) are in good condition (e.g. no sign of impacts or damage).

2.2 Check that the balise and support plates are securely fixed and free from damage.

2.3 Check distribution boxes are secure, free from damage and water ingress.

2.4 Check ballast clearance under the balise is between 5 and 10cm.

2.5 Remove all debris, fire risks and potential hazards.

2.6 Check the BCB encoding plug (fixed signal balise) or the cable plug coupler (switchable signal balise) is securely fixed and free from damage.

2.7 Carry out NR SMS/PartB Test 209 Section 1 – Balise Test.

2.8 Carry out NR SMS/PartB Test 209 Section 2 – Presense Train Test

PERIODIC TASK

3. Replace BCC Plug

3.1 Swap the in service BCC plug of the encoder rack with a correctly coded replacement.

This task shall be carried out using NR/SMTH/Part04/BA13 – Replace a KVB Encoding Plug.

3.2 With the UCS maintenance card connected verify that that no errors are present in the encoder memory record log.

All faults shall be investigated. Details of each fault shall be passed to the SM(S).

Additional information on fault finding can be found in NR/SMTH/Part10/FF26 (Faulting Guide : KVB Balise).

END

Includes:	All Swing Bridges listed in the table
Excludes:	Banavie (Canal) See BR12

GENERAL

The Signal Engineer is responsible for the Signallers panel. This incorporates controls and indications for the Bridge operation. The signalling interlocking also has inputs and outputs to and from the Bridge control gear. There is always some control and indication circuitry that involves both plant and signalling responsibility and a suitable boundary point for those circuits will have been agreed.

Swing Bridges are located at:

Goole	Swing
Hull River	Swing Bridge
Keadby (Canal)	Draw Bridge
Keadby (River)	-
Selby	Swing Bridge
Oulton Broad	Swing Bridge
Reedham (River)	Swing Bridge
Somerleyton (River)	Swing Bridge

Keadby (River) Bridge is also known as King George V Bridge, Althorpe. This used to be a drawbridge but is now permanently fixed. While there is no rail alignment detection at this bridge, the Signal Engineer is responsible for the navigation lights which are light proved and indicated in Keadby Gate Box. At all other bridges, the navigation lights are a plant responsibility.

Signallers of Swing bridges have the following indications of the state of the bridges:

GREEN: Bridge Home, Bridge Bolts in, Rail Alignment Detected.
YELLOW: Bridge Home, Bridge bolts in, but no Rail Alignment Detection.
RED: Bridge Not Home (Bridge Open).

The Rail alignment Detection is proved in all signals leading over the bridge. It is more sensitive than the bridge bolts and there might be cases where the bridge bolts can go home but Rail Alignment cannot be obtained. Where rail alignment detection cannot be obtained, but the Plant Engineers bolts have been detected home, a yellow indication is given to the Signaller. Local instructions generally allow trains to pass over the bridge at low speed after cautioning.

Oulton Broad, Reedham (River), Somerleyton (River) have “Spagnoletti needle” indicators in the Signal box/cabin (see Appendix B).

SERVICE A

1. Point Machine and Fittings

1.1 Carry out maintenance to the point machine driving the rail Alignment Detection in accordance with the relevant NR/SMS/PartC/PCxx series Service A, for hydraulic machines use NR/SMS/PartC/PB11 Service A. Also see NR/SMS/PartC/PA01 & NR/SMS/PartC/PF02 for the rodding and cranks.

2. Rail Alignment Detectors

(Goole, Keadby Canal, Hull & Selby) - refer to Appendix A.

(Oulton Broad, Reedham, & Somerleyton) - refer to Appendix B.

2.1 With the detector blade normal, gauge the tolerance between each side of the blade and inner faces of the detector block, the total of which shall not be more than 8mm (5/16”), if a limit switch is provided or 12mm (1/2”) without.

2.2 Gauge the blade width to confirm wear is not taking place on the blade. The width shall be 25mm (1”) (Goole, Keadby Canal, Hull, & Selby)or 70mm (2 3/4”) (Oulton Broad, Reedham & Somerleyton), the acceptable tolerance being 3mm (1/8”). If these tolerances are exceeded advise your SM(S) as the blade requires replacing.

2.3 Gauge rail ends with a straight edge, measure any misalignment and record.

2.4 Where provided, measure the distance between the limit switch operating arm roller (at the point of contact with the detector blade) to the unoperated central position:

If these measurements are not within ± 4mm (5/32”) then the roller has worn excessively below its normal 19mm (3/4”) diameter and the lever arm shall be renewed.

If subsequently the settings above are not obtainable the complete switch and existing arm shall be replaced.

2.5 With the detector plunger reversed (withdrawn) check that the limit switch operating lever (if fitted) has self-restored to the un-operated centre position at 90° to the plane of the detector blade (0° to the switch).

2.6 If fitted, examine limit switch contact assembly, special attention being given to the moving contact tension springs. Excessive wear of the contact requires the fixed and moving contacts to be replaced with new assemblies.

2.7 If a limit switch is fitted, operate lever arm with the detector blade and observe the contact assembly for correct operation and engagement of the lever arm in the blade bevel. Confirm that the roller rotates.

2.8 Examine terminations clean and protect as necessary.

2.9 Examine cables to limit switches and confirm they are not chafing at gland entries.

2.10 Lightly lubricate moving parts and bearings of limit switch (if fitted) with mineral oil. Confirm correct tension is available upon the operating lever whilst observing the operation, by hand, of the mechanical linkage.

2.11 Test for correct operation of 'IN' and 'OUT' indications by operation from the cabin. The 'coarse' normal and reverse proving of the blade shall make within 12mm (1/2") of the end of the travel. The blade shall not be withdrawn to a position further than flush with the detector side edge of the first guide block on the adjacent bridge mounting.

2.12 Apply lithium-based grease to grease nipples and detection plunger.

2.13 Apply mineral oil to stud connections, screw threads, and lid fixing screws.

2.14 Repeat 2.1 to 2.13 for all remaining detectors.

2.15 Test by operation from bridge cabin or signal box.

3. Bridge Indications

(Goole, Keadby Canal, Hull, Selby Oulton Broad, Reedham & Somerleyton).

3.1 In the Signal box, if practical, observe the Bridge indications through a complete opening and closing cycle of the bridge. If it is not practical to observe a complete cycle, then function test the rail alignment detection and check that the signalling interlocking releases and subsequently locks the bridge operating controls and the indications for those parts of the cycle are correctly displayed.

3.2 The Anglia bridges have an indication "bridge home". In addition to 3.1 examine the brass rod, internal contacts and springs on the bridge and check they are operating correctly. Clean as necessary.

4. Navigation Lights

(**Keadby River Bridge Only)**

4.1 Test operation of lamp proving by making a disconnection. Check Signal Box receives "light out" alarms and correct indications.

SERVICE B

5. Point Machines and Fittings

Carry out maintenance to the point machine driving the rail Alignment Detection in accordance with the relevant NR/SMS/PartC/PCxx series Service B, for hydraulic machines use NR/SMS/PartC/PB11 Service B. Also see NR/SMS/PartC/PA01 & NR/SMS/PartC/PF02 for the rodding and cranks.

6. Wedges

(Goole, Hull & Selby Oulton Broad, Reedham & Somerleyton Only)

6.1 Function Test the operation of each limit switch on the bridge by monitoring with an AVO meter on the limit switch circuit while the bridge is operated.

6.2 If any adjustment, repair, or renewal of a limit switch is required it shall always be done in conjunction with the E&P Engineer.

7. Emergency Release

7.1 Where provided, test operation of emergency release and key token pilot working facilities.

8. Electrical Disengager (Goole only)

Electrical Disengagers are unique to Goole Swing Bridge. They are large plug and socket connectors mounted on the open edge of the bridge carrying the Signalling controls and indications to adjacent signals and signal boxes. They are required to disengage and separate before the bridge can move.

When the Disengagers separate, electrical power is maintained on the bridge by a UPS that is provided by the E&P Engineer.

8.1 Wipe and examine disengager and mechanical connections.

8.2 Examine bearings, turned pins and spilt pins in disengager mechanical connections for excessive wear or slackness.

8.3 Examine cables and confirm that they are not chafing, especially at gland entry.

8.4 Clean and examine individual contact pins.

8.5 Lubricate with contact fluid.

8.6 Apply mineral oil sparingly to disengager guide pins, disengager slides and mechanical connections. Remove any surplus.

8.7 Apply lithium-based grease to grease nipples.

8.8 Test Disengagers from the Signal box for correct operation.

9. Overhead Cable Route

9.1 Examine suspender fastenings as necessary.

9.2 Lubricate centre pin and shackles on swing span termination with mineral oil.

9.3 Examine cable sheath for signs of chafing.

APPENDIX A - Goole, Keadby Canal, Hull & Selby

Excludes:	All Other Swing Bridges

GENERAL

The Signal Engineer is responsible for the Signallers panel. This incorporates controls and indications for the Bridge operation. The signalling interlocking also has inputs and outputs to and from the Bridge control gear. There is always some control and indication circuitry that involves both plant and signalling responsibility and a suitable boundary point for those circuits will have been agreed.

Signallers of Swing bridges have the following indications of the state of the bridges:

GREEN:	Bridge Home, Bridge Bolts in, Rail Alignment Detected.
YELLOW:	Bridge Home, Bridge Bolts in, but no Rail Alignment Detection.
RED:	Bridge Not Home (Bridge Open).

The Rail alignment Detection is proved in all signals leading over the bridge. It is more sensitive than the bridge bolts and there may be cases where the bridge bolts can go home but Rail Alignment cannot be obtained.

Where rail alignment detection cannot be obtained, but the Plant Engineers bolts have been detected home, a yellow indication is given to the Signaller. Local instructions generally allow trains to pass over the bridge at low speed after cautioning.

SERVICE A

1. Point Machine and Fittings

1.1 Carry out maintenance to the point machine driving the rail Alignment Detection in accordance with the relevant NR/SMS/PCxx series Service A, for hydraulic machines use NR/SMS/PB11 Service A.

1.2 Carry out NR/SMS/PA01 & PF02 for the rodding and cranks

1.3 Carry out NR/SMS/LV31 for the circuit controllers.

2. Rail Alignment Detectors

Refer to Appendix A

2.1 With the detector blade normal, gauge the tolerance between each side of the blade and inner faces of the detector block, the total of which shall not be more than 8mm (5/16”), if a limit switch is provided or 12mm (1/2”) without.

2.2 Gauge the blade width to confirm wear is not taking place on the blade. If these tolerances are exceeded advise your SM(S) as the blade requires replacing.

2.3 Gauge rail ends with a straight edge, measure any misalignment and record.

2.4 Where provided, measure the distance between the limit switch operating arm roller (at the point of contact with the detector blade) to the unoperated central position:

If these measurements are not within ± 4mm (5/32”) then the roller has worn excessively below its normal 19mm (3/4”) diameter and the lever arm shall be renewed.

If subsequently the settings above are not obtainable the complete switch and existing arm shall be replaced.

2.5 With the detector plunger reversed (withdrawn) check that the limit switch operating lever (if fitted) has self-restored to the un-operated centre position at 90° to the plane of the detector blade (0° to the switch).

2.6 If fitted, examine limit switch contact assembly, special attention being given to the moving contact tension springs. Excessive wear of the contact requires the fixed and moving contacts to be replaced with new assemblies.

2.7 If a limit switch is fitted, operate lever arm with the detector blade and observe the contact assembly for correct operation and engagement of the lever arm in the blade bevel. Confirm that the roller rotates.

2.8 Examine terminations clean and protect as necessary.

2.9 Examine cables to limit switches and confirm they are not chafing at gland entries.

2.10 Lightly lubricate moving parts and bearings of limit switch (if fitted) with mineral oil. Confirm correct tension is available upon the operating lever whilst observing the operation, by hand, of the mechanical linkage.

2.11 Test for correct operation of ‘IN’ and ‘OUT’ indications by operation from the cabin. The ‘coarse’ normal and reverse proving of the blade shall make within 12mm (1/2”) of the end of the travel. The blade shall not be withdrawn to a position further than flush with the detector side edge of the first guide block on the adjacent bridge mounting.

2.12 Apply lithium-based grease to grease nipples and detection plunger.

2.13 Apply mineral oil to stud connections, screw threads, and lid fixing screws.

2.14 Repeat 2.1 to 2.13 for all remaining detectors.

2.15 Test by operation from bridge cabin or signal box.

3. Bridge Indications

3.1 In the Signal box, if practical, observe the Bridge indications through a complete opening and closing cycle of the bridge. If it is not practical to observe a complete cycle, then function test the Rail Alignment detection and check that the signalling interlocking releases and subsequently locks the bridge operating controls and the indications for those parts of the cycle are correctly displayed.

SERVICE B

4. Point Machines and Fittings

4.1 Carry out maintenance to the point machine driving the rail Alignment Detection in accordance with the relevant NR/SMS/PartC/PCxx series Service B, for hydraulic machines use NR/SMS/PartC/PB11 Service B.

4.2 Carry out NR/SMS/PartC/PA01 & NR/SMS/PartC/PF02 for the rodding and cranks.

4.3 Carry out NR/SMS/PartC/LV31 for the circuit controllers.

5. Overhead Cable Route

5.1 Examine suspender fastenings as necessary.

5.2 Lubricate centre pin and shackles on swing span termination with mineral oil.

5.3 Examine cable sheath for signs of chafing.

APPENDIX A - Rail Alignment Detector Tolerances

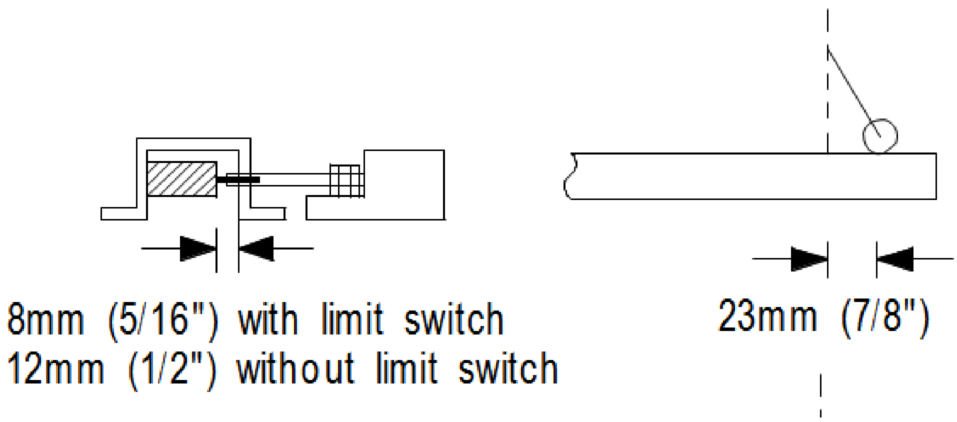

Figure 1 – Rail Alignment Detector Tolerances

END

Includes:	Keadby - King George IV Bridge
Excludes:	All other Navigation Lights (Lanterns)

GENERAL

The Navigation lights are manufactured by Pelangi, Part No PA2835 DRG PL2212 Assembly.

All Navigation lights are LED lanterns manufactured by Pelangi Type No PL83.

There are eight lanterns on the bridge:

There are six duplicated LED units on (NE)Red, (NC)Green, (NW)Yellow, (SE)Red, (SC)Green, (SW)Yellow [all with “TOP” and “BOTTOM” lanterns], and two single LED units for (NORTH)Yellow, (SOUTH)Yellow navigation lanterns.

SERVICE B

1.1 Check that the light unit is undamaged, secured to the bridge structure and correctly aligned.

1.2 Examine the tail cable and cable entry glands.

1.3 Examine the internal wiring and terminations. Protect as necessary inclusive of disconnection boxes.

1.4 Check that all the LED’s are lit and visually check the quality of the aspect corresponds to the diagrams.

1.5 Record all LED voltages at the corresponding disconnection boxes NR/SMS/PartR/T021/RC05 (Signal – LED).

1.6 Clean the exterior of the LED light units.

1.7 Disconnect each LED in the control case and check the corresponding LED extinguishes and the NAV LIGHTS ECR de-energises check the functionality of the NAV LIGHTS EK with monitoring SB, repeat all other LED’s (Due to the restricted access on the bridge it is acceptable to disconnect the individual LED’s in the signalling location).

END

Includes:	Main Air Systems
Excludes:	All other Air Systems

The air main pump is the responsibility of the Plant Engineer and falls within the scope of the legislation on pressure vessel testing. Staff required to work on this equipment shall be specially authorised.

Air mains for point operation typically operate at 60 psi (Bar 4.14). Care should be taken when connecting or adjusting sections of pipe / hose.

The air main for the section concerned shall be isolated before replacement parts are fitted.

SERVICE A

1. External

1.1 Inspect the visible air main throughout the full length, including cross track routes and connections.

a) Check pipes, joints, supports and fixings.

b) Remove, where practicable, fire risks, physical obstructions.

c) Check cover plates and air main protection. Repair leaks where practicable (e.g. tighten joints).

1.2 Report outstanding defects as corrective maintenance, e.g.

a) Subsidence, collapses.

b) Outstanding leaks.

c) Mechanical damage.

1.3 Release fluid contaminants using the air main bleed point (where provided).

END

SERVICE A

1. Primary Cells (if Fitted)

Carry out NR/SMS/PartB/Test/058 (Primary Cell Test).

Continually loaded cells should be replaced if their obtained readings indicate they can fail before the next maintenance visit. See NR/SMS/PartC/EL00 (Electrical Equipment – General).

1.1 Check the number of cells is correct.

2. Secondary Cells (if Fitted)

NOTE: *This service is not required if the batteries are "Maintenance Free"*

2.1 Clean and examine all exteriors and cases.

2.2 Check the level of electrolyte - top up with distilled/ionised water as necessary.

NOTE: *This task should be completed after Clause 4.1 if being done together with a SERVICE B.*

SERVICE B

3. Batteries & Cells – General (Includes "Maintenance Free" Batteries)

3.1 Check warning signs (e.g., No Smoking) and P.P.E. signs (Goggles, Gloves etc).

3.2 Clean and examine batteries, cells, straps and terminations (use insulated box spanner).

3.3 Protect terminations as necessary.

Arrange for defective cells to be replaced. If a cell in a crate is found to be faulty, replace the whole crate.

4. Lead Acid Cells (If Fitted)

4.1 Test the specific gravity on each cell is a minimum of 1.220.

Specific gravity measurements are to be taken before any top up of the cell with distilled water, as this could give a false reading.

Readings below this value can indicate that the cell is reaching the end of its life and should be reported to your SM(S).

5. Secondary Cells

5.1 Check that there is enough ventilation over the top of the cells.

5.2 Check that the correct number and type of cells along with the correct charger are fitted according to the diagram.

Changes might have been made during corrective maintenance. More details are in NR/SMS/PartC/EL00 (Electrical Equipment – General).

5.3 Carry out NR/SMS/PartB/Test/055 (Secondary Cell Test).

6. Final Checks

6.1 Before leaving site, check that covers, doors and locks are properly fitted and secure.

END

Includes:	TEML41, when configured as Remote Control System, Panel Multiplexer, Train Describer, Fault Reporting System or Network Interface Processor Interface equipment, and associated cubicles contained in equipment or relay rooms
Excludes:	All other TEML 41 configurations and Control Systems, Equipment/Relay rooms (associated equipment), SSI, IECC or other complete control systems

NOTE: *DC voltages can still be present on internal and external connections with the 110v supply turned off.*

General

Record all results on the system test record sheet.

Advise your SM(S) if any of these tests fail to meet the requirement.

In some cases, not all of the equipment detailed in this SMS is installed for each system configuration, therefore only the tasks relevant to equipment provided shall be undertaken. If you are in doubt, ask your SM(S).

Remote Control System

The Remote Control System is typically is made up of 4 sub-systems:

- Remote Interlocking Indications Processor (RIIP).
- Remote Interlocking Controls Processor (RICP).
- Panel Processor (PP).
- Signal Controls Processor (SCP).

The RIIP and RICP are located at the field (Interlocking), and the PP and SCP (Office) at the Control Centre.

The SCP send controls to the RICP, the RIIP sends indications to the PP. The PP also send indications to the SCP and Train Describer.

Panel Multiplexer (PMUX)

A PMUX forms the interface between Signaller’s controls and an SSI interlocking.

Train Describer (TD)

A TD provides the Signaller with train identification information and passes this information to interested systems (SMART and other TD’s).

Fault Reporting System (FRS)

An FRS provides centralised fault reporting for a number of systems.

Network Interface Processor (NIP)

A NIP provides the interface between a Train Describer and an Automatic Routing System (ARS).

Power Supplies

Most power supplies are duplicated, and when in normal service perform 'Power Sharing'. The power supplies are 'diode fed' to parallel them together.

This is achieved on the back plane for the 5V logic and communications supplies, and on the distribution blocks for the Input/Output supplies.

To correctly test the power supply levels, only one supply shall be turned on when testing the voltage level, this also makes sure that a single power supply can operate the system if one of a duplicated pair fail.

Voltage tests shall be carried out on the Backplane for 5v levels and distribution blocks for Input/Output supplies.

DAILY SERVICES

1. Fault Logging Systems

This can include the Technicians' terminal.

1.1 If provided, check the fault logging system for any outstanding faults. Rectify or report. This can be a screen display and/or a printout depending on the system.

1.2 If provided, check any associated printer(s) have enough paper and ink/toner. Rectify or report.

REGULAR SERVICE

2. Data Logger Systems

2.1 If provided, check that data logging is being undertaken correctly by analysis of a sample of information. Transfer archive data from the HD to removable recording media (floppy, CD-R or flash memory).

SERVICE A

3. Technicians' Terminal

These are not provided on all systems.

3.1 Check the correct time and date are displayed. Rectify as necessary.

4. Indications and Alarms

4.1 If provided, check that system status indications on the Signallers' alarm/status panel and any system indications on the control/interface or modem equipment are not showing any alarms or faults. If any are found, rectify or report.

If you are unsure about any indications or alarms, ask your SM(S).

Any corrective actions shall be logged with ICC/NRIFC.

Details of the indications can be found in the NR/SMS system tests appendixes.

On control and interface systems depending on the system configuration, indications can be at both office and field ends.

5. Equipment Cubicles

5.1 Check (if provided) cubicle cooling fans are working and any filters are clean. Rectify as necessary.

6. Control and Interface Equipment

6.1 Visually check that all leads, panels, cards, units, fastenings, and connectors are secure.

7. Power Supplies

7.1 For systems with A and B supplies measure the DC output from each PSU unit, if the measured voltage is out of tolerance it shall be adjusted or replaced.

Supply	Volts	Limits	Ripple	Test Point	Systems
Logic 'A'	+5V	5.1V to 5.25V	< 50mV	5V1 and 0V1	ALL
Logic 'B'	+5V	5.1V to 5.25V	< 50mV	5v2 and 0V2	ALL
Comms 'A'	+5V	5.1V to 5.25V	< 50mV	5CB1 and 0V1	ALL
Comms 'B'	+5V	5.1V to 5.25V	< 50mV	5CB2 and 0V2	ALL
Alarm 'A'	+24V	23.5V to 24.5V	< 50mV	Alarm Common Terminals	ALL
Alarm 'B'	+24V	23.5V to 24.5V	< 50mV	Alarm Common Terminals	ALL

Supply	Volts	Limits	Ripple	Test Point	Systems
Input ‘A’	+24V	23.5V to 24.5V	< 50mV	Input Common Terminals	RIIP, PP, SCP, FRS
Input ‘B’	+24V	23.5V to 24.5V	< 50mV	Input Common Terminals	RIIP, PP, SCP, FRS
Output ‘A’	+12V	11.5V to 12.5V	< 50mV	Output Common Terminals	SCP & PP
Output ‘B’	+12V	11.5V to 12.5V	< 50mV	Output Common Terminals	SCP & PP
Output ‘A’	+50V	11.5V to 12.5V	< 50mV	Output Common Terminals	RICP
Output ‘B’	+50V	11.5V to 12.5V	< 50mV	Output Common Terminals	RICP
Modem ‘A’	-5V	-5.1V to -5.25V	<50mV	-5CB1 and 0V1	RIIP, RICP, PP, SCP, TD
Modem ‘B’	-5V	-5.1V to -5.25V	<50mV	-5CB2 and 0V1	RIIP, RICP, PP, SCP,TD

Table 1 – Voltage Limits

8. Fault Terminal

For systems with an FRS:

8.1 Enter ‘PFLTS’ <RTN> and investigate any reported faults. Also look at the FRSPC fault history and assess any ‘recurring’ faults.

For systems with dedicated fault terminals:

8.2 Enter ‘PFLTS’ <RTN> on each Technicians Terminal and investigate any reported faults.

9. General Observations

9.1 Check the Processor ‘Active’ LED has a discernible ‘flicker’.

9.2 Check the Active Communications channels Red/Green LED’s active during message transmission.

9.3 Check the Status Card ‘Flash’ LED pulsing 1sec on, 1 sec off.

10. Final

10.1 On completion of tasks, check that any equipment cubicle doors are securely closed and as necessary locked.

10.2 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

SERVICE B

11. Equipment Cubicles

11.1 Clean the exterior surfaces and carefully dust the interior of equipment cubicles using a dry lint free cloth.

12. Control and Interface Equipment

12.1 Dust the equipment casings and panels using a dry lint free cloth. Check that leads and connectors are not disturbed during cleaning.

12.2 If provided, disconnect and clean all keyboards as necessary.

12.3 If provided, clean all monitor screens and housings with a proprietary anti-static dry screen cleaner.

12.4 If provided, and if necessary, disconnect and clean any tracker or mouse ball and rollers. This is necessary if the operation has become intermittent or jerky.

12.5 If provided, check the front air intake filters on all PC based equipment, clean or renew as necessary.

12.6 If provided, check the Althorn (formally Rugby) clock for correct operation.

13. System Change – Over

This test shall be carried out during ‘Engineering’ hours.

13.1 Ascertain which system is ‘Master’ by looking at the Status Card.

13.2 Turn the changeover key towards the ‘Slave’ indication on the status card.

13.3 Verify the system is fully operational (Communications, Input and Outputs).

13.4 Check that No Faults are reported on FRS or connected Technicians Terminal.

14. Line Protection and Route Selection

14.1 If provided, carry out NR/SMS/PartB/Test/062 (Line Protection Unit Test).

14.2 If provided, carry out NR/SMS/PartB/Test/149 (Electronic Route Selection Equipment (ERSE) Test).

15. Spares

15.1 Where no test rack facility for the system exists, check any system spares are correctly stored in anti-static bags or boxes.

15.2 Where a test rack or other functional spares assembly for the system exists, check that all the spare cards/units are correctly fitted into the rack. If requested to by your SM(S), test the operation of the cards/units in the test rack.

16. Final

16.1 On completion of tasks, check that any equipment cubicle doors are securely closed and as necessary locked.

16.2 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

APPENDIX A - System Indications

System Status Panel (RIIP, RICP, PP, SCP)		
LED	**Normal State**	**Failed State**
SPA Fail	Extinguished	System Processor 'A' Failed
SPB Fail	Extinguished	System Processor 'B' Failed
Comms A Fail	Extinguished	Communications channel 'A' failed between Interlocking and Control Centre
Comms B Fail	Extinguished	Communications channel 'B' failed between Interlocking and Control Centre
TEML41 Fault	Extinguished	System Fault – See Technicians Terminal or FRS

Table 2 - System Status Panel (RIIP, RICP, PP, SCP) Indications

Table 4 - System Status Panel (PMUX, TD, NIP) Indications

END

Includes:	DM11 systems configured as a TDM remote control system or a panel / train describer multiplexer. Interface equipment, and associated cubicles contained in equipment or relay rooms
Excludes:	All other Control Systems, Equipment/Relay rooms (associated equipment), SSI, IECC or other complete control systems

General

Record all results on the system test record sheet.

Advise your SM(S) if any of these tests fail to meet the requirement.

A remote-control system involves the transmission of data between locations called office and field.

An office is a location that transmits controls and receives indications, a field station is one that receives controls and transmits indications.

A panel/train describer multiplexer forms either the interface between the Signaller’s controls and a SSI interlocking or an interface between a relay interlocking and a train describer.

The DM11 in either TDM or PMUX/TDMUX configurations consists of a 38U high cubicle incorporating a 6U high TDM or PMUX/TDMUX rack, dual auxiliary AC to DC power units and internal cabling.

The processor modules operate in a control and standby configuration, the changeover and alarm unit that is either on the Signaller’s panel or in the cubicle controls this.

In some cases, not all of the equipment detailed in this SMS is installed for each system configuration, therefore only the tasks relevant to equipment provided shall be undertaken. If you are in doubt, ask your SM(S).

DAILY SERVICES

1. Fault Logging Systems

This can include the Technicians’ terminal.

1.1 If provided, check the fault logging system for any outstanding faults. Rectify or report. This can be a screen display and/or a printout depending on the system.

1.2 If provided, check any associated printer(s) have enough paper and ink/toner. Rectify or report.

REGULAR SERVICE

2. Data Logger Systems

2.1 If provided, check that data logging is being undertaken correctly by analysis of a sample of information. Transfer archive data from the HD to removable recording media (floppy, CD-R or flash memory).

SERVICE A

3. Technicians' Terminal

These are not provided on all systems.

3.1 Check the correct time and date are displayed. Rectify as necessary.

4. Indications and Alarms

4.1 If provided, check that system status indications on the Signallers' alarm/status panel and any system indications on the control/interface or modem equipment are not showing any alarms or faults. If any are found, rectify or report.

If you are unsure about any indications or alarms, ask your SM(S).

Any corrective actions shall be logged with ICC/NRIFC.

Details of the indications can be found in the NR/SMS system tests appendixes.

On control and interface systems depending on the system configuration, indications can be at both office and field ends.

5. Equipment Cubicles

5.1 Check (if provided) cubicle cooling fans are working and any filters are clean. Rectify as necessary.

6. Control and Interface Equipment

6.1 Visually check that all leads, panels, cards, units, fastenings, and connectors are secure.

7. Final

7.1 On completion of tasks, check that any equipment cubicle doors are securely closed and as necessary locked.

7.2 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

SERVICE B

8. Equipment Cubicles

8.1 Clean the exterior surfaces and carefully dust the interior of equipment cubicles using a dry lint free cloth.

9. Control and Interface Equipment

9.1 Dust the equipment casings and panels using a dry lint free cloth. Check that leads and connectors are not disturbed during cleaning.

9.2 If provided, disconnect and clean all keyboards as necessary.

9.3 If provided, clean all monitor screens and housings with a proprietary anti-static dry screen cleaner.

9.4 If provided, and if necessary, disconnect and clean any tracker or mouse ball and rollers. This is necessary if the operation has become intermittent or jerky.

9.5 If provided, check the front air intake filters on all PC based equipment, clean or renew as necessary.

9.6 If provided, check the Althorn (formally Rugby) clock for correct operation.

10. DM11 Cubicle (TDM & PMUX/TDMUX)

10.1 In liaison with the Signaller, force a changeover to the standby processor using the switch on the changeover and alarm panel.

a) Check that the standby processor is now in control and the previous control processor is in standby by observing the ‘Sel’ LEDs on the 68P processor modules.

b) Return the changeover switch to the middle (Auto) position on systems that have an automatic changeover facility.

10.2 Check that any alarms raised have been cleared and no faults have been introduced to the system.

a) LED indications shall be as in Appendix B (Table 2).

b) The audible alarm needs to be acknowledged by means of the acknowledgement switch on the changeover panel.

10.3 Measure using a meter and/or oscilloscope the following DC voltages and AC ripple on the 6PP power supply test points as detailed in the Table 1 below:

Supply	Volts	Limits	Ripple
Logic	5V	4.7V to 5.5V	<50mV
Logic	7V	6.5V to 7.5V	<50mV
Interface	12V	11.5V to 12.5V	<50mV

Table 1 - DC Voltages

10.4 Plug a Technicians terminal or laptop PC into the engineering port of the processor module (Port A) and check the external channel ‘ack’, ’nak’ and ‘no-response’ counts using the PCCZ (Print Channel Count & Zero) command.

a) Check that the sum of the ‘nak’ and ‘no-response’ counts is less than 10% of the ‘ack’ count.

b) If the count is greater, this could be an indication of a problem on the telecoms line. A note should be made of this so that trends can be analysed.

11. DM11 Cubicle (TDM Only)

11.1 Measure using a meter the modem Tx and Rx levels: -35dBm.

a) Check the obtained level against those previously obtained.

Investigate any significant variations.

11.2 Check that the spare program proms and database disks are available and current for all the systems.

11.3 Measure using an oscilloscope the 48V DC output to the TDM power supplies.

11.4 Check that the obtained waveform is as in Appendix A (Figure 1). If the lower limit of the waveform is less than 38V, replace the PSU.

12. Line Protection and Route Selection

12.1 If provided, carry out NR/SMS/PartB/Test/062 (Line Protection Unit Test).

12.2 If provided, carry out NR/SMS/PartB/Test/149 (Electronic Route Selection Equipment (ERSE) Test).

13. Spares

13.1 Where no test rack facility for the system exists, check any system spares are correctly stored in anti-static bags or boxes.

13.2 Where a test rack or other functional spares assembly for the system exists, check that all the spare cards/units are correctly fitted into the rack. If requested to by your SM(S), test the operation of the cards/units in the test rack.

14. Final

14.1 On completion of tasks, check that any equipment cubicle doors are securely closed and as necessary locked.

14.2 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

APPENDIX A - Waveform

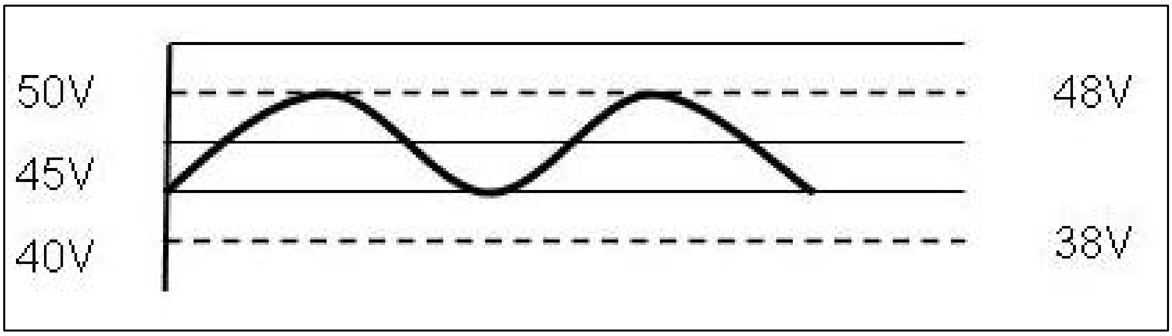

Figure 1 - Waveform Example of PSU Output

APPENDIX B - LED Indications

Indication	Location	State
Interface	6PP Power Supplies	Illuminated
Logic		
Watchdog 'WD'	68P Processor Modules	Illuminated
Available 'Av'		
Selected 'Sel'	68P Processor Modules	Illuminated (Controlling processor)
		Extinguished (Standby Processor)
Scan (x2)	6SI Configured I/PModules	Flashing
Scan	6S0 Configured O/P modules	Flashing (Controlside)
		Extinguished (Standby side)

Table 2 - LED Indications

END

Includes:	Delphin 1024 and 256 systems configured as a remote control TDM system (RC/TDM), a panel and interlocking interface unit (PIIU), a panel multiplexer (PMUX), a crossing interface processor (XIP), or a train describer multiplexer (TDMUX), Interface equipment, and associated cubicles contained in equipment or relay rooms
Excludes:	All other Control Systems, Equipment/Relay rooms (associated equipment), SSI, IECC or other complete control systems

General

Record all results on the system test record sheet.

Advise your SM(S) if any of these tests fail to meet the requirement.

In some cases, not all of the equipment detailed in this SMS is installed for each system configuration, therefore only the tasks relevant to equipment provided shall be undertaken. If you are in doubt, ask your SM(S).

System Configurations

The remote-control time division multiplexer (RC/TDM) system is used in applications requiring a one to one relationship between inputs and outputs at each end of the system.

The panel and interlocking interface unit (PIIU) is used in applications that require indications meshing and/or route ring processing between a control centre and an interlocking.

The panel multiplexer (PMUX) system forms the interface between the Signaller's controls and an SSI interlocking.

The crossing interface processor (XIP) forms the interface between level crossing controls/indications and the computer based interlocking driving the level crossing control relays.

The train describer multiplexer (TDMUX) system forms the interface between an interlocking and a train describer.

Always check you know the configuration of the Delphin 1024 system you are working on, see the notes on system types in NR/SMS/PartC/IC00 (VDU Based Control Systems General) & NR/SMS/PartC/SB00 (Signal Box Control & Operating Systems General).

Not all of the tests in this SMS can be relevant for each system configuration therefore only the tasks relevant to system configuration should be undertaken. If you are in doubt, ask your SM(S).

Delphin 1024

The Delphin 1024 system consists of an 8U high EMC sub rack incorporating a 6U high euro rack.

Each controller crate is fitted with dual power supplies and processor modules (CMP-A/B) that can access/scan common input modules, (CMI) and common output modules (CMO).

On the RC/TDM and PIIU configurations each processor module is fitted with a serial link to communicate with its corresponding field/office counterpart.

The processor modules operate in a control and standby configuration, the changeover and alarm module (CCO-A /CCO-B) controls this.

The CCO-A/CCO- B provides both an automatic and manual changeover along with (where implemented) an equipment fault alarm (EFA).

DAILY SERVICES

1. Fault Logging Systems

This can include the Technicians’ terminal.

1.1 If provided, check the fault logging system for any outstanding faults. Rectify or report. This can be a screen display and/or a printout depending on the system.

1.2 If provided, check any associated printer(s) have enough paper and ink/toner. Rectify or report.

REGULAR SERVICE

2. Data Logger Systems

2.1 If provided, check that data logging is being undertaken correctly by analysis of a sample of information. Transfer archive data from the HD to removable recording media (floppy, CD-R or flash memory).

SERVICE A

3. Technicians’ Terminal

These are not provided on all systems.

3.1 Check the correct time and date are displayed. Rectify as necessary.

4. Indications and Alarms

4.1 If provided, check that system status indications on the Signallers' alarm/status panel and any system indications on the control/interface or modem equipment are not showing any alarms or faults. If any are found, rectify or report.

If you are unsure about any indications or alarms, ask your SM(S).

Any corrective actions shall be logged with ICC/NRIFC.

Details of the indications can be found in the NR/SMS system tests appendixes.

On control and interface systems depending on the system configuration, indications can be at both office and field ends.

5. Equipment Cubicles

5.1 Check (if provided) cubicle cooling fans are working and any filters are clean. Rectify as necessary.

6. Control and Interface Equipment

6.1 Visually check that all leads, panels, cards, units, fastenings, and connectors are secure.

7. Visual Checks

In cases where a single PIIU is used as an interface between a Crossing Control Panel or a Mimic Control Panel and a Modular Control System (MCS), carry out task 7.1 to 7.10 and 9.

However, in cases where two PIIUs are used as an interface between a Control Panel and an interlocking, follow tasks 8.1 to 8.9 and 9.

For system indications refer to Appendix A.

7.1 Check that the interface and logic indication LEDs on the CPW power are lit.

7.2 Check that all module power (Pwr) indication LEDs are lit. This should be checked for all of the following modules:

a) CMP-P1.

b) CCO.

c) CMM-A.

d) CMI.

e) CMO.

7.3 Where fitted, check that the power LEDs on the modems is lit.

7.4 Where fitted, check that the DCD LEDs on the modems are lit.

7.5 Check that the Watchdog (WD) LED is flashing and Available (Av) LED is lit on both CMP-P1 modules.

One of these modules shall be selected as being in control and this can be indicated by the ‘Sel’ LED being lit on the selected module.

7.6 For PIIUs with a field end, check that the same CMP-P1 module is in control at both the office and the field. (Field/Office PIIU only).

7.7 Check that both the scan LEDs are lit on all configured input modules.

7.8 Check that the scan LED representing the CMP-P1 selected as being in control is either on or flashing on the configured CMO modules. Note: either state is acceptable, both scan LEDs off is not.

7.9 Check that the power LED’s are lit for any other external power supplies where these have been supplied.

7.10 Where fitted, check status of surge protector units and take action as follows:

a) Green lit only – Full protection – No action.

b) Green and Red lit – Reduced protection – Replace unit within one week.

c) Red lit only – No protection – Replace unit immediately.

7.11 Where modems are fitted, plug a Technician’s terminal or laptop into the engineering port of the ‘online’ processor module (RS232C Port ‘A’ on the front of the CMP-P1) running ‘monitor’ program, or run hyper terminal set-up to 4800baud, no parity, 8 data bits and 1 stop bit.

7.12 Check the external ‘ack’, ‘nak’ and ‘no response’ counts using the PCCZ (Print Channel Count and Zero) command.

7.13 Check that the sum of the ‘nak’ and ‘no response’ counts is less than 10% of the ‘ack’ count. If it is greater, this points to a telecoms problem.

7.14 Record this detail on the record card, so that the trend can be analysed.

7.15 Update the date and time by using the DATE and TIME commands.

8. System Status (RC/TDM & PIIU systems only)

For system indications refer to Appendix A.

8.1 For systems that have office and field units, these tests are to be carried out on both units.

8.2 Where modems are fitted, plug a Technician's terminal or laptop into the engineering port of the 'online' processor module (RS232C Port 'A' on the front of the CMP-P1) running 'monitor' program, or run hyper terminal set-up to 4800baud, no parity, 8 data bits and 1 stop bit.

8.3 Check the external 'ack', 'nak' and 'no response' counts using the PCCZ (Print Channel Count and Zero) command.

8.4 Check that the sum of the 'nak' and 'no response' counts is less than 10% of the 'ack' count. If it is greater, this points to a telecoms problem and should be reported to your SM(S) as corrective maintenance.

8.5 Record all details on the record card.

8.6 If required, update the date and time by using the DATE and TIME commands.

9. System Changeover (all systems)

Liaison with the Signaller.

9.1 Before proceeding, check for faults by ensuring the fault light on either processor is not illuminated.

9.2 At the office end, force a changeover to the standby CMP-P1 module using the 'Auto' switch on the front panel of the CCO module.

9.3 Check that the standby CMP-P1 module is now in control by ensuring that the 'Sel' LED is illuminated. The CMP-P1 module that was previously in control should now be in standby mode.

This can be checked by confirming that the 'Sel' LED is extinguished and the 'WD' LED is still flashing.

9.4 Check that the scan LEDs on the CMO modules now represents the newly selected processor module.

9.5 Check that the changeover switch is returned to the auto position and that any alarms that can have been raised have been cleared by using the Alarm/Ack switch on the CCO module. Confirm that no faults have been introduced onto the system by checking the EFA LED is out.

9.6 Check that no system faults have occurred.

9.7 On PIIU and RC/TDM systems use the logger system, on PMUX and TDMUX systems check the fault LED.

9.8 Record all details on the card. This includes the date and time of the changeover.

10. Final

10.1 On completion of tasks, check that any equipment cubicle doors are securely closed and as necessary locked.

10.2 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

SERVICE B

11. Equipment Cubicles

11.1 Clean the exterior surfaces and carefully dust the interior of equipment cubicles using a dry lint free cloth.

12. Control and Interface Equipment

12.1 Dust the equipment casings and panels using a dry lint free cloth. Check that leads and connectors are not disturbed during cleaning.

12.2 If provided, disconnect and clean all keyboards as necessary.

12.3 If provided, clean all monitor screens and housings with a proprietary anti-static dry screen cleaner.

12.4 If provided, and if necessary, disconnect and clean any tracker or mouse ball and rollers. This is necessary if the operation has become intermittent or jerky.

12.5 If provided, check the front air intake filters on all PC based equipment, clean or renew as necessary.

12.6 If provided, check the Althorn (formally Rugby) clock for correct operation.

13. System Measurements (all systems)

The different system configurations cannot have all the same components; readings are to be taken as fits the system.

13.1 Check that any alarms raised have been cleared and no faults have been introduced to the system.

13.2 Check the LED indications are correct see Appendix A for details.

The audible alarm needs to be acknowledged by means of the acknowledgement switch on the CCO-A/CCO-B module.

13.3 If provided, measure using a meter, the following DC voltages on power supply test points:

Test Point	Voltage (dc)
7VL logic	between 6.5V & 7.5V
12VIF interface (on CPW-A)	between 11.5V & 12.5V
24VIF interface (on CPW-D)	between 23V and 25V

Table 1 – Test Point Voltages

If any are outside the specified range, the CPW-A requires changing.

13.4 If provided, measure the modem levels at the line termination points:

Cable Pair	Values
Transmission (Tx)	nominal -13dBm
Receive (Rx)	between -13dBm and -30dBm

Table 2 – Modem Levels

13.5 If provided, measure the voltages on external power supplies:

Supply	Voltage (dc)
External 12V	between 10.5V & 13.5V
External 24V	Between 21.5V & 26.5V
External 48V	Between 44V& 63V

If any are outside the specified range, the power supply requires changing.

13.6 If provided, check that the logger and archive PCs are powered up.

14. Line Protection and Route Selection

14.1 If provided, carry out NR/SMS/PartB/Test/062 (Line Protection Unit Test).

14.2 If provided, carry out NR/SMS/PartB/Test/149 (Electronic Route Selection Equipment (ERSE) Test).

15. Spares

15.1 Where no test rack facility for the system exists, check any system spares are correctly stored in anti-static bags or boxes.

15.2 Where a test rack or other functional spares assembly for the system exists, check that all the spare cards/units are correctly fitted into the rack. If requested to by your SM(S), test the operation of the cards/units in the test rack.

16. Final

16.1 On completion of tasks, check that any equipment cubicle doors are securely closed and as necessary locked.

16.2 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

APPENDIX A - System Indications

Not all module types are fitted to every system and there can be more than one module type.

Modules	Function	LED(s)
CPW	Interface and logic	Illuminated
CMP-A/B	Module power (Pwr)	Illuminated
CCO		
CMM-A		
CMI		
CMO		
DCD	Modems	Illuminated
CMP- A/B[#1]	Watchdog (WD)	Flashing
	Available (Av)	Illuminated
	Selected (Sel)	Illuminated on one module only
CMI (configured)	Scan	Illuminated
CMO (configured)	Scan	Flashing # 3
		Extinguished # 4
External PSUs [# 2]	Power	Illuminated

1: For RC/TDM & PIIUs with a field end, check that the same CMP-A/B module is in control at both the office and the field end.

Check that the scan LED representing the CMP-A/B selected as being in control is either on or flashing on the configured CMO modules.

Either state is acceptable, both scan LEDs off is not and shall be investigated.

2: As provided.

3: Controlling module.

4: Standby module.

END

Includes:	Sapphire T48, Communication Processor, MCS Concentrator MCS, Train Describer (TD), SpadAlert and Interface equipment, and associated cubicles contained in equipment or relay rooms
Excludes:	All other Control Systems, Equipment/Relay rooms (associated equipment), SSI, IECC or other complete control systems

General

Before working on system use an ESD wrist strap connected to the Earth Bonding Point on the cubicle.

Record all results on the system test record sheet.

Advise your SM(S) if any of these tests fail to meet the requirement.

The Sapphire T48 is a communications processor system that interfaces to computer-based interlocking's (e.g. VHLCs) and a Signaller's panel via a Delphin1024 PIIU. The comms processor receives all controls from a Delphin1024 PIIU via dual serial links.

The system can process this data and transfer these controls, based on the rules within its database, to the remote interlocking's (VHLCs). All indications data from the remote interlocking's is passed by the comms processor to the Delphin1024 PIIU, which drives the panel indication lamps.

When configured as a train describer, the database configures the SapphireT48 channels for use as a stepping Dual TD or as an Information TD. It can also be used as an interface between a Modular Control System and as SPAD alert system.

Refer to the GETS maintenance manual for each system configuration for more information.

System Configuration

Always check you know the configuration of the Sapphire T48 system you are working on, see the notes on system types in NR/SMS/PartC/IC00 (VDU Based Control Systems General) & NR/SMS/PartC/SB00 (Signal Box Control & Operating Systems General).

Not all the tests in this SMS are relevant for each system configuration therefore only the tasks relevant to system configuration should be undertaken. If you are in doubt, ask your SM(S).

Sapphire T48 Communications Processor

The Communications Processor is a system in a signal box that interfaces to computer-based interlocking's like VHLCs and a Signaller's panel via a Delphin1024 PIIU.

The Comms Processor receives all Controls from a Delphin1024 PIIU via dual serial links.

The system can process this data and transfer these controls, based on the rules within its database, to the remote interlocking's (VHLCs). All indications data from the remote interlocking's is passed by the Comms Processor to the Delphin1024 PIIU, which drives the panel indication lamps.

Sapphire T48 MCS Concentrator

The MCS Concentrator is a system in a signal box that interfaces to a number of Signaller's MCS systems and uses the data to provide information to Supervisors or Maintainers Workstation positions.

This allows the supervisor to view maps on his single workstation that are on the various Signallers' MCS workstations and acknowledge relevant alarms.

Sapphire T48 MCS

The MCS is a system in a signal box that interfaces to a number of Interlocking's, either SSI or Relay (via the Delphin1024) and the Signaller's Workstations.

The SapphireT48 consists of a duplicated system with automatic changeover. There are two identical processing elements labelled A and B within the 8U crate, whichever side is online is referred to as the Control side and the other as the Standby.

When the SapphireT48 is cold started, the element labelled A boots up first and takes 'Control', thus it is the default 'Control' side.

The 'Control' side scans its watchdog inputs and those of the 'Standby' side; if it has stopped pumping its own watchdog and the 'Standby' is pumping its watchdog an automatic changeover should occur.

The 'Standby' then becomes the 'Control' and vice versa. However, to prevent continual switching under certain fault conditions further automatic changeovers are prevented until a manual reset has taken place.

Sapphire T48 Train Describer (TD)

The TD consists of a system in a signal box connected to a Signallers Panel Display system and Signalling Input systems.

The TD system receives all signalling and train movements from TD Multiplexers and SSIs via dual serial links.

The system can process this data and step trains according to the rules within its database and display this on the panel displays and Operator Control Units and interface with other adjacent TDs for boundary steps.

The TD database configures the SapphireT48 channels for use as a stepping Dual TD or as an Information TD.

Sapphire T48 SPADAlert

The SpadAlert consists of a system in a signal box connected to an MCS system.

The SpadAlert system receives all signalling and train movements from the MCS Control Equipment (CE) via a dual link.

The system can process this data and any alarms generated shall be sent to the control equipment for displaying on the workstations and recording on the logger PC. A SpadAlert system can only be connected to a single MCS CE.

WEEKLY SERVICES

1. Fault Logging Systems

This can include the Technicians' terminal.

1.1 If provided, check the fault logging system for any outstanding faults. Rectify or report. This can be a screen display and/or a printout depending on the system.

1.2 If provided, check any associated printer(s) have enough paper and ink/toner. Rectify or report.

REGULAR SERVICE

2. Data Logger Systems

2.1 If provided, check that data logging is being undertaken correctly by analysis of a sample of information. Transfer archive data from the HD to removable recording media (floppy, CD-R or flash memory).

SERVICE A

3. Technicians' Terminal

These are not provided on all systems.

3.1 Check the correct time and date are displayed. Rectify as necessary.

4. Indications and Alarms

4.1 If provided, check that system status indications on the Signallers' alarm/status panel and any system indications on the control/interface or modem equipment are not showing any alarms or faults. If any are found, rectify or report.

If you are unsure about any indications or alarms, ask your SM(S).

Any corrective actions shall be logged with ICC/NRIFC.

Details of the indications can be found in the NR/SMS system tests appendixes.

On control and interface systems depending on the system configuration, indications can be at both office and field ends.

5. Equipment Cubicles

5.1 Check (if provided) cubicle cooling fans are working and any filters are clean. Rectify as necessary.

6. Control and Interface Equipment

6.1 Visually check that all leads, panels, cards, units, fastenings, and connectors are secure.

7. System Status

7.1 Check that the indications LED's on the DPW-A Power Supply Modules are lit, ON.

7.2 Check that all the module power 'Pwr' indications, LED's are lit, ON, i.e. check the DCP-K2/K4, DSS-A, DMS and DMX modules.

7.3 Check that the Watchdog 'WD' LED on the 'Comms' section of both processor modules, DCP-K2/K4, are lit, ON and one of the processors is in control, selected ('Sel' LED is lit, ON)

7.4 Check that the time on the DRC-A module is accurate.

7.5 Check that the peripheral units (Technicians' terminal and workstation) are functional.

7.6 On the Technician's terminal select the processor that is in control and confirm that all the links are OK by using the FLTS (Link Fault Status) command.

7.7 Check the external channel 'ack', 'nak' and 'no- response' counts using the PCCZ (Print Channel Count and Zero) command. Check that the sum of 'nak' and 'no-response' counts is less than 10% of the 'ack' count.

If it is greater this can point to a problem on the link, and should be reported to your SM(S).

On systems without a Technicians' terminal, a laptop computer can be connected to the system.

8. System Changeover

In liaison with the Signaller.

8.1 Before proceeding, check that the fault light on either processor is not illuminated.

8.2 Manually force a changeover to the standby processor by momentarily pushing up the processor modules 'select' switch. Check that the 'select' switch is returned to the auto position.

On some system configurations this is achieved by switching the select switch to 'Disable' on the on-line processor to bring the standby processor on-line, then switching to 'Auto'. If you are in doubt, ask your SM(S).

8.3 Check that the standby processor is now in control, selected ('Sel' LED is lit, ON) and the other processor is now in standby, not selected ('Sel' LED is not lit, OFF).

8.4 Check that any alarms raised have been cleared and that no faults have been introduced to the system. Depending on the system configuration, these alarms can be on the Signaller's panel.

Repeat Step 7.6 on the processor that is now in control.

Record all details on the card. This includes the date and time of the changeover.

9. Final

9.1 On completion of tasks, check that any equipment cubicle doors are securely closed and as necessary locked.

9.2 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

SERVICE B

10. Equipment Cubicles

10.1 Clean the exterior surfaces and carefully dust the interior of equipment cubicles using a dry lint free cloth.

11. Control and Interface Equipment

11.1 Dust the equipment casings and panels using a dry lint free cloth. Check that leads and connectors are not disturbed during cleaning.

11.2 If provided, disconnect and clean all keyboards as necessary.

11.3 If provided, clean all monitor screens and housings with a proprietary anti-static dry screen cleaner.

11.4 If provided, and if necessary, disconnect and clean any tracker or mouse ball and rollers. This is necessary if the operation has become intermittent or jerky.

11.5 If provided, check the front air intake filters on all PC based equipment, clean or renew as necessary.

11.6 If provided, check the Althorn (formally Rugby) clock for correct operation.

12. System Measurements

12.1 Measure using a meter the voltages on the DPW-A test points:

Supply	Voltage (DC)
6V	Between 5.5V & 6.5V
5V	Between 4.75V & 5.25V

Table 1 – Supply Voltages

If any are outside the specified range, the DPW-A requires changing.

13. System Maintenance

13.1 On systems provided with a hot spares crate, check the modules are functional and check that the Program and Database is current.

13.2 Check that the spare Program and Database disks are available and current for all the systems by comparing with the labels on the SapphireT48 Processor Modules (DCP-K2) or by using the ISSU command on the Technician’s terminal.

TD Systems Only:

13.3 Check that the peripheral units (OCUs, Display Distributors, and Displays) are functional by checking with the relevant Signaller.

14. Line Protection and Route Selection

14.1 If provided, carry out NR/SMS/PartB/Test/062 (Line Protection Unit Test).

14.2 If provided, carry out NR/SMS/PartB/Test/149 (Electronic Route Selection Equipment (ERSE) Test).

15. Spares

15.1 Where no test rack facility for the system exists, check any system spares are correctly stored in anti-static bags or boxes.

15.2 Where a test rack or other functional spares assembly for the system exists, check that all the spare cards/units are correctly fitted into the rack. If requested to by your SM(S), test the operation of the cards/units in the test rack.

16. Final

16.1 On completion of tasks, check that any equipment cubicle doors are securely closed and as necessary locked.

16.2 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

END

Includes:	Older type MCS systems, Interface equipment, and associated cubicles contained in equipment or relay rooms
Excludes:	MCS systems based on a Delphin 1024 or a Sapphire T48 platform and all other Control Systems, Equipment/Relay rooms (associated equipment), SSI, IECC or other complete control systems

General

Record all results on the system test record sheet.

Advise your SM(S) if any of these tests fail to meet the requirement.

In some cases, not all of the equipment detailed in this SMS is installed for each system configuration, therefore only the tasks relevant to equipment provided shall be undertaken. If you are in doubt, ask your SM(S).

DAILY SERVICES

1. Fault Logging Systems

This can include the Technicians' terminal.

1.1 If provided, check the fault logging system for any outstanding faults. Rectify or report. This can be a screen display and/or a printout depending on the system.

1.2 If provided, check any associated printer(s) have enough paper and ink/toner. Rectify or report.

REGULAR SERVICE

2. Data Logger Systems

2.1 If provided, check that data logging is being undertaken correctly by analysis of a sample of information. Transfer archive data from the HD to removable recording media (floppy, CD-R or flash memory).

SERVICE A

3. Technicians' Terminal

These are not provided on all systems.

3.1 Check the correct time and date are displayed. Rectify as necessary.

4. Control and Interface Equipment

4.1 Visually check that all leads, panels, cards, units, fastenings, and connectors are secure.

4.2 Check (if provided) cubicle cooling fans are working and any filters are clean. Rectify as necessary.

5. Workstation Map Display Projector(s) (Where Provided)

Refer to the manufacturer's manual for cleaning and adjustment instructions.

5.1 Check all the air filters, clean as necessary.

5.2 Check the projector lens, clean as necessary.

5.3 Check the projected picture, adjust as necessary.

6. Control Equipment Cubicle

The following procedure checks that the 'standby' control equipment is serviceable by forcing a manual changeover. It shall only be carried out during light traffic periods in liaison with the Signaller.

6.1 Check the LED indications in auxiliary changeover crate one.

The select LED on the front of the 3AC-AX module connected to one of the controller crates will be illuminated. This indicates that this is the control system; the other system is the standby.

The watchdog LED's are illuminated on the 3AC-AX modules for both controller crate A and B.

6.2 List all the current faults using the 'EFAS' and 'FLTS' commands on the fault logger.

If any indication is not correct or if faults are logged for either the control or standby equipment, follow the fault-finding procedures in the maintenance manual before proceeding.

6.3 Press the select switch on the standby 3AC-AX module in the auxiliary changeover crate one to manually select the standby system. Observe the systems switch over.

6.4 List all the current faults using the 'EFAS' and 'FLTS' commands on the fault logger. Compare with the previous listing and investigate any differences.

6.5 Record the results in the system logbook.

7. Dual Workstation Changeover (Where Provided)

These tests should only be carried out during light traffic periods in liaison with the Signaller.

These tests should be repeated for each workstation with a 10 minute gap between each changeover. This is to check that the system recovers and any faults arising can be identified and cleared.

7.1 Check that the Signaller's keyboard and tracker ball are working correctly and that all the screen displays are OK.

7.2 Check that a standby workstation PC is serviceable by forcing a manual changeover as detailed in section 6.

7.3 Observe the workstation monitors for the correct display and observe a few operations of the keyboard and tracker ball.

a) List all current system faults using the 'EFAS' and 'FLTS' commands on the fault logger.

b) Check for any workstation malfunctions.

7.4 Record the results in the system logbook.

8. Power Supplies

8.1 Using a meter and/or oscilloscope measure the DC voltages and AC ripple on all the auxiliary changeover controller modules (control/slave 3AC- AX/SX) using the monitoring points on the front panels:

System	Limits	Ripple
7V Logic	6.5V to 7.5V	<50mV
+12V Interface	+10.8V to +13.2V	
-12V Interface	-10.8V to -13.2V	

Table 1 - Voltages Auxiliary Changeover Controller Modules

8.2 Using a meter and/or oscilloscope Measure the DC voltages and AC ripple on the power supply voltages on each control equipment crate power supply module (6PP-N):

System	Voltage	Ripple
5V Logic	4.5V to 5.5V	<50mV
+12V Interface	+10.8V to +13.2V	
-12V Interface	-10.8V to -13.2V	

Table 2 - Voltages Control Equipment Crate

NOTE: *Replace any module with readings outside the ranges detailed in 8.1 & 8.2.*

9. Final

9.1 On completion of tasks, check that any equipment cubicle doors are securely closed and as necessary locked.

9.2 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

SERVICE B

10. Equipment Cubicles

10.1 Clean the exterior surfaces and carefully dust the interior of equipment cubicles using a dry lint free cloth.

11. Control and Interface Equipment

11.1 Dust the equipment casings and panels using a dry lint free cloth. Check that leads and connectors are not disturbed during cleaning.

11.2 If provided, disconnect and clean all keyboards as necessary.

11.3 If provided, clean all monitor screens and housings with a proprietary anti-static dry screen cleaner.

11.4 If provided, and if necessary, disconnect and clean any tracker or mouse ball and rollers. This is necessary if the operation has become intermittent or jerky.

11.5 If provided, check the front air intake filters on all PC based equipment, clean or renew as necessary.

11.6 If provided, check the Althorn (formally Rugby) clock for correct operation.

12. Line Protection and Route Selection

12.1 If provided, carry out NR/SMS/PartB/Test/062 (Line Protection Unit Test).

12.2 If provided, carry out NR/SMS/PartB/Test/149 (Electronic Route Selection Equipment (ERSE) Test).

13. Spares

13.1 Where no test rack facility for the system exists, check any system spares are correctly stored in anti-static bags or boxes.

13.2 Where a test rack or other functional spares assembly for the system exists, check that all the spare cards/units are correctly fitted into the rack. If requested to by your SM(S), test the operation of the cards/units in the test rack.

14. Final

14.1 On completion of tasks, check that any equipment cubicle doors are securely closed and as necessary locked.

14.2 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

Periodic Task

15. Routine Replacement

These tasks are applicable only to the earlier versions of GETS Modular Control Systems not the Delphin 1024 or Sapphire T48 based systems.

NOTE: *The tasks can be undertaken by Technical Support staff and/or equipment specialists, your SM(S) will advise you.*

15.1 Replace the following equipment cooling fans on each PC with new units of the same type. Check after replacement that each fan works correctly

- PC front air intake (x2).
- Internal PC processor fan.
- PC power supply.

15.2 Replace on each PC the internal clock and Bios chip battery with a new battery of the same type.

15.3 Replace on each PC the hard disk drive (HD) with a new HD of the same type.

15.4 Workstation Map Display Projector(s): Where provided, arrange for each projector to be sent to an approved service centre for servicing and fan replacement.

END

Includes:	Machine operated and mechanical operated detonator placers
Excludes:	All Other types of detonator placers

SERVICE A

1. All Detonator Placers

1.1 Check all detonators are in date. Replace any that have passed their expiry date.

Disposal of expired detonators shall be in accordance with current environmental policy.

2. Machine Operated Detonator Placer

2.1 Reference should be made to the following NR/SMSs for details of maintenance on this equipment:

a) NR/SMS/PartC/SG95 (Semaphore Signal Machine (BP, GRS, & SGE).

b) NR/SMS/PartC/SG96 (Semaphore Signal Machine (WRSL)).

3. Mechanical Operated Detonator Placer B.S. type

3.1 Examine the following items:

a) Split pins.

b) Holding down bolts. Tighten where necessary.

3.2 Examine and brush/wipe the following items:

a) Casing.

b) Roller.

c) Straight crank.

d) All Connections.

3.3 Lubricate with mineral oil the following items.

a) Roller shaft.

b) Crank pin.

c) Lid hinge.

4. Mechanical Operated Detonator Placer Clayton Type

<u>Exterior</u>

4.1 Examine the following items:

a) Split pins.

b) Holding down bolts.

c) Tighten where necessary.

4.2 Examine and brush/wipe the following items:

a) Body.

b) Connections.

c) Lever quadrant.

4.3 Lubricate with mineral oil the following items.

a) Turned pins in connections.

b) Lever centre pin.

<u>Interior</u>

4.4 Examine split pin in jaw pin.

4.5 Examine and wipe the following items:

a) Operating arm.

b) Operating bar.

c) Gear wheel.

d) Lower jaw and jaw fixing screw. Tighten where necessary.

4.6 Lubricate with lithium based grease.

a) Cam face.

b) Operating bar.

c) All grease nipples.

4.7 Lubricate trigger pin cam fixing bolt and jaw pin with mineral oil if grease nipples are not fitted.

5. Final (All Types)

5.1 Test by operation from the signal box.

END

Any deficiency or failure, which could affect the safe running of trains or the integrity of the signalling system shall be reported to the Signaller immediately and escalated as a fault.

1. Hazards Associated with Electrical Supplies

The Electricity at Work Regulations 1989 requires precautions to be taken against the risk of death or injury from electricity in work applications.

2. Principle – Live Working Prohibition

No work, other than taking electrical measurements is permitted on live equipment if:

a) The working voltage is 175V or more, or the short circuit current can exceed 25A.

AND

b) This is on exposed conductors or terminals, which can be touched by the person doing the work.

3. Exceptions

Where there is an instruction permitting the work, which details the procedures to be followed, the training required and the tools to be used, live work may be undertaken. In such circumstances, the following standards apply:

a) The person carrying out the work shall be accompanied.

b) Use the specified tools.

c) The insulation of hand tools should be inspected before use.

d) Use the specified PPE (e.g. rubber gloves, mats and eye protection).

4. Taking Measurements Where the Voltage or Current Can Exceed the Above Limits

The following precautions shall be followed:

a) Staff shall be accompanied.

b) The measuring instrument shall be the type approved for the work.

c) If using an unfused meter, HRC fused leads shall be used.

d) Prods shall be fitted with finger barriers

e) Bare metal at the prod ends should not exceed 2mm.

f) The use of crocodile clips and clip on prods is prohibited.

g) Meter leads and prods shall be carefully checked for security and insulation prior to use.

5. High Voltage Insulation Testers

These testers (e.g. Megger) can be used where the voltage they produce exceeds 175V as the short circuit current is restricted to a safe level.

6. Isolation

Before work starts on electrical equipment, it shall be isolated unless:

a) The working voltage is less than 175V and the short circuit current cannot exceed 25A.

OR

b) The work does not involve exposed terminals or conductors that can be touched by the person doing the work.

OR

c) It is unreasonable for the circuit to be isolated.

7. Local Disconnection of Equipment

Where the person doing the work can verify that the equipment is not reconnected and is not electrically live; no additional precautions are required.

Options include removal of plug and socket, links, fuses or operation of switches.

If the person doing the work cannot verify that the equipment cannot be reconnected, PROTECTIVE ISOLATION shall take place.

8. Protective Isolation

This shall always be employed for work on 650V power supplies. The following procedure applies:

a) Until the equipment has been proved to be isolated, it shall be assumed to be live.

b) Identify all necessary disconnection points using the diagrams.

c) Isolate the equipment from the rest of the system using switches fuses or links.

d) Fuses, links, and locking off keys are retained by the person doing the work.

e) A notice worded 'Danger Work In Progress – Do Not Reconnect' shall be secured by each isolation point.

f) Where possible, switches shall be locked off using a personal key. Where this is not possible, a personal padlock may be used to secure the equipment housing. Alternatively, a reliable person shall be stationed at the disconnection point to check that no one reconnects the supply other than the person doing the work. This person shall not have any other duty and shall not leave his/her post.

g) Before starting work, the circuit shall be tested for no voltage present. This shall include a check that any capacitors have been discharged

h) Shift changeover shall be planned to confirm that the person responsible for the isolation is clearly identified.

i) Only the person responsible for the isolation may restore it.

Where work involves more than one team, a multi-user lock off device shall be employed where possible.

Where the work is pre-planned, involves more than one team and it is not possible to provide protection as described above, a permit to work system shall be employed.

9. Touch Potential Risk

There is a risk where metallic items (location cases, metallic fences, concentrators, lever frames etc) do not have equipotential bonding and are connected to different earths.

Under certain fault conditions this can lead to an electric shock if the two items having different earths are touched simultaneously.

It is advisable if the earth bonding on an asset is unknown not to touch metallic items that are physically separate at the same time.

10. Signalling Circuit Insulation Testing

Insulation testing of signalling circuits detects deterioration or failure of the insulation of wires, cables or other circuit components. This function can be achieved by continuous monitoring or periodic testing.

10.1 Continuous Monitoring – SSI Trackside Functional Modules (TFMs)

An SSI TFM provides continuous monitoring of its outputs; any feed on an output which should not be there causes the unit to go into a safe operating mode.

No additional testing (e.g. busbar earth test) is required for equipment connected directly to an SSI TFM output.

Where an SSI TFM operates a relay, earth testing to NR/SMS/PartB/Test/051 (Busbar Earth Tests) or NR/SMS/PartB/Test/053 (Earth Leakage Detector (ELD) : Testing and Calibration) shall be required to the supply busbars.

TFM inputs are not continuously monitored. If you are in doubt, ask your SM(S).

10.2 Continuous Monitoring – Earth Leakage Detectors (ELDs)

An ELD provides continuous monitoring of all equipment connected to a busbar against any extraneous connection to earth. It does not detect problems that are not associated with a connection to earth (e.g. core to core insulation).

ELDs require to be calibrated correctly to provide correct monitoring; details in NR/SMS/PartB/Test/053 (Earth Leakage Detector (ELD) : Testing and Calibration) shall be followed.

10.3 Periodic Testing – Busbar Earth Testing

Where continuous monitoring is not provided, busbar earth testing is required to test the insulation of signalling circuits connected to busbar under test.

As per the monitoring provided by ELDs this test does not detect problems that are not associated with a connection to earth.

10.4 Periodic Testing – Cable Insulation Testing

This tests individual conductors for insulation from each other (e.g. multi core cable) and also from earth.

It is more onerous than busbar testing and requires the conductors to be disconnected from their associated circuits, therefore only the conductors are tested, not the associated equipment. Details of the test are in NR/SMS/PartB/Test/054 (Cable Insulation Tests).

10.5 Earth Testing and Earth Looping Testing

Earthing on incoming mains power supplies from an external source (e.g. fed from a consumer unit, 240V and above) is the responsibility of the E&P function.

This usually means that the earthing for equipment and relay rooms that have these power supplies fed into them has been installed and is maintained by E&P.

Earthing for signalling power supplies (110V and below), trackside locations, and equipment/relay rooms that do not have an incoming mains power supply from an external source (e.g. incoming 240V or above is fed from another equipment/relay room or trackside location) is usually installed and maintained by signalling.

The correct testing of these signalling earths requires specialist equipment, if you suspect there are any deficiencies with the earth itself or the continuity of the looping; you should report it as corrective maintenance NR/SMS/PartA/A02 (Preventative and Corrective Maintenance). The SM(S) shall arrange for the earth to be tested to the current standards.

11. Hazards Associated with Secondary Cells

11.1 General Precautions and Prevention of Explosions

Alkaline and lead acid cells give off explosive gas during the charging cycle.

Always observe safety directives and local instructions and, before starting work, check good circulation of air to disperse accumulated gases.

Open doors and check ventilation. Enforce air circulation by wafting or fanning where ventilation seems poor. NEVER tap cells to check electrolyte level or loosen battery connections whilst the cells are on charge or discharge and gassing.

DO NOT use hydrometers or distilled water top up bottles that have been used for the maintenance of alkaline cells on acid cells and vice-versa. Acid destroys alkaline cells and alkaline destroys acid cells.

Plastic cases have to be cleaned using a damp cloth. Dry cloths can cause a build-up of static electricity.

Connections shall be tight and properly made to avoid sparking and to maintain good conductivity.

Do not use excessive force. Use Insulated Box Spanners.

Short Circuit Risks

The outer case of steel cased cells is live. Never allow tools or metallic objects to rest across the cells as this might cause sparking and damage.

Care should be taken not to short out any cells during testing/maintenance as this might result in a short circuit current high enough to cause splashes of molten metal and possible explosion.

Use Insulated tools and test leads.

Beware of rings, watches with metal straps or any other jewellery you might be wearing.

The physical size of the cell is not necessarily indicative of its power. The 5Ah Cyclon cell can produce 200A and should be treated with as much care as larger cells.

11.2 Action in Case of Accident

EYES – Immediately wash liberally with water, following the instructions on the eyewash bottle and seek immediate medical attention.

SKIN – Rinse liberally with water and seek medical attention.

CLOTHING – Remove contaminated clothing as soon as possible.

SPILLAGE – Swill down spillage with water as soon as possible.

NOTE: Never swill down spillage in substations where there is high tension electrical equipment. Report the situation.

11.3 Secondary Cells – General

The rate of charging is dependent on the size and type of cell.

Whilst the function of lead acid and alkaline cells is similar, the chemical composition is different. Both types usually require regular topping up. Use only distilled or de-ionised water and do not over-fill.

Some cells are sealed (e.g. Cyclon) and do not require topping up.

The tops of cells should be kept clean, terminations of unsealed cells being protected with petroleum jelly.

Inter-cell connectors should be kept clean and firmly fitted.

Bare metal straps should be protected with petroleum jelly. Replace corroded or defective straps.

If a cell has to be moved, check straps and terminations before moving to check they do not break or become disconnected.

11.4 Secondary Cells – Installation

Connections are the correct polarity, tight and straps serviceable.

The bottom gland retaining nuts of Alkaline cells are torqued by the manufacturer and should not be altered.

Transit stoppers should be removed; vent caps free to open and electrolyte the correct level.

11.5 Disposal of Cell Material

Cells are to be disposed of as per the NR Environmental Policy.

11.6 Charging Rates

Constant Voltage Chargers (CVC) are set to the correct voltage per cell connected.

Match the correct charger to the number and type of cells. No adjustment is possible.

Non-constant Voltage Chargers require the charging rate to be set to give the minimum trickle charge necessary to keep the battery in a fully charged state under normal operating conditions.

Where intermittent peak loads occur, a slightly higher charging rate might be required.

Continual overcharging of a battery should be avoided as this produces excessive quantities of explosive gas.

11.7 Power Off Circuitry

The operation of a battery charger is usually proved in the circuitry of some automatic level crossings. You should always liaise with the monitoring point before switching the charger on or off.

To prove charger operation, switch off the battery charger and connect a voltmeter across the terminals of one cell.

Switch on the charger and observe the voltage reading slowly increase, which indicates that the charger is working.

11.8 Cyclon Cells

These are 'sealed for life' cells therefore topping up is not required.

Only a CVC to BR spec 1875, 955 or 928 (or equivalent) shall be used to charge Cyclon Cells, otherwise overheating occurs.

11.9 ALCAD Vantage Cells

Vantage cells are of a ultra-low maintenance type, if correctly set up and maintained they should only require topping up approximately every ten years.

Only a CVC to BR spec 1875, 955 or 928 (or equivalent) shall be used on Vantage cells.

These cells are pressurized. When topping up, slowly remove pressure vent cap to release pressure.

Do not place the filler neck into the cell. Position over vent cap opening and inject distilled water, observing the level on external fill lines.

11.10 Primary Cells

CEGASA air alkaline cells are a replacement for the SAFT air saline cells which have gone out of production. CEGASA cells have a more stable voltage-over-time characteristic (the voltage does not gradually reduce with age) therefore the cell voltage cannot be used as an indication of the remaining capacity of CEGASA cells.

There is no test available to routinely check battery capacity on CEGASA cells, replacement of them should be based on experience of typical battery life.

The capacity of the new CEGASA cells is at least as good as the old SAFT cells but can be affected by extreme low temperatures and high humidity.

Cells should be replaced at the same intervals as they were in the past taking into account the cell capacity (e.g. if a GEGASA 200Ah cell is used to replace a SAFT 100Ah cell it can be expected to have double the life).

12. Hazards Associated with Cables & Wiring

Problems and Hazards associated with cables and wiring are described in detail in NR/L3/SIG/19012 (SIGTAN 12). Technicians should be aware of the dangers when working in the vicinity of wiring and electrical terminations:

a) To check that metal tools do not come into contact with circuit components.

b) To avoid damaging insulation materials.

Certain sites are subject to wire degradation and should be looked for during maintenance visits. This manifests itself in two forms, dry degradation, or wet degradation.

12.2 Dry Wire Degradation

This causes the inner rubber insulation to lose elasticity, thus becoming dry and crumbly. If the wire is not disturbed, the outer PCP cover continues to convey a visual impression of good condition.

Bending or twisting affected wires might cause the insulation to break, therefore exposing the bare conductor.

Wiring in the vicinity of heat sources or in a warm, dry environment is particularly vulnerable. Brittle and cracked wiring shall be reported.
Wet Wire Degradation

This occurs where the inner rubber turns to a sticky liquid, which runs out of the PCP cover if the wire is vertical.

Report wiring that show signs of bulging, sponginess and leakage.

12.3 The Management of Affected Sites

The labelling and detailed working restrictions of these sites are specified in standard maintenance procedures.

Rodent damage and chafing (sharp metallic corners) These shall be reported to your SM(S)

12.4 Cable Clamps

These should be properly fitted to prevent snagged cables causing a short circuit. See Figure 1.

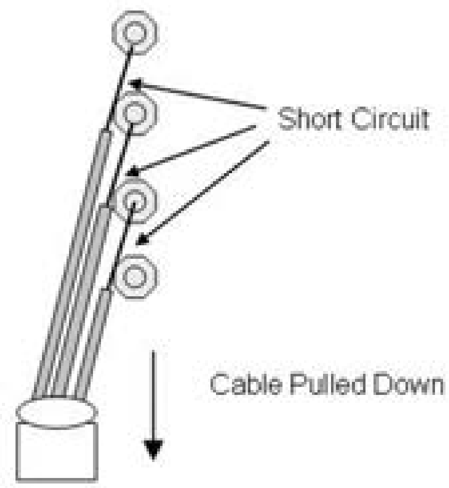

Figure 1 – Short circuits caused by cable being unsupported

12.5 Binding Posts

These are often found in locations and relay rooms as a space saving method of terminating cables without a disconnection point.

Wrong side failures have been caused in the past where a link has incorrectly been fitted to a pair of binding posts and has strapped out a circuit contact.

To prevent this from happening, red dome nuts should be fitted to all binding posts. This indicates that a link **SHALL NOT BE FITTED**.

If it is necessary to remove a cable core terminated on a binding post, only one dome nut of a pair should be removed at any one time.

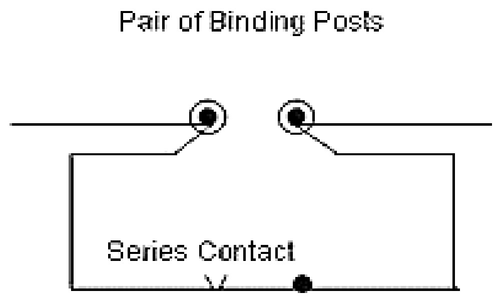

Figure 2 – Use of Binding Posts

12.6 Un-Terminated and Disconnected Wires

These shall be fully disconnected at both ends and suitably insulated or preferably removed to prevent the risk of short circuit. The methods of insulation are listed below:

a) ENDCAPS - May be used as a permanent insulation when the wire is cut as a blunt end.

b) BOMBTAILS - May be used as a permanent insulation with the wire cut away from any apparatus.

The following temporary insulation methods may be used for a maximum of 12 weeks:

a) End Caps (with wire stripped).

b) Squeeze on Sleeves.

c) Expandable Sleeves.

d) Bomb Tails (wire not cut away).

e) Plastic bags.

13. Shelf Type Relays

These and similar equipment might be a hazard where horizontally mounted terminals are fitted. This might result in a short circuit if a metallic object is dropped into the terminals. This risk may be minimized by fitting the terminals with insulated caps.

14. Hazards Associated with Relays

14.1 Relay Bases.

BR spec 829 relay bases can be found in 3 colours:

a) Black.

b) Blue.

c) White/Cream.

Black bases are made from a phenolic resin (which is dark brown) with carbon added to make it a black colour.

Blue bases are made from an epoxy resin (which is colourless) with a pigment added to make them blue.

White/Cream bases are made from a melamine resin which is naturally white/cream in colour.

14.2 Silver Migration

Black relay bases are made of phenolic resin; because of this they are susceptible to silver migration. This happens when under certain conditions the phenolic resin can become conductive by the movement of metallic silver from plated conductors over and into the base.

To overcome this problem blue bases, made out epoxy resin were used. The cost of making these bases out of this material was very high so another material was sought; this has led to the current White/Cream bases made from melamine resin.

Black phenolic bases are usually found in older installations. Lineside apparatus cases and unheated relay rooms present the greatest risk and elimination of black bases is targeted at these sites.

Heated relay rooms might also be affected.

Relay base changing and visual sampling programs form part of the maintenance schedule. Precise details should be obtained from your SM(S).

Full details of the technical requirements are contained in NR/L2/SIG/11107.

14.3 Relay Servicing

Relay servicing programs should form part of the annual maintenance plan. Details of servicing requirements are contained within the relay servicing plan.

Some relay functions have a mandatory servicing frequency of 10 years maximum, unless exempted by a risk analysis. These are:

a) Timer relays (BR937, 946, 947, 962, AEI-GS AS).

b) Magnetically latched or magnetic stick relays (BR935, 936).

c) Relays used in biased or polar circuits (BR932, 961, Tyers G1, Shelf type).

d) Track relays (BR938, 939, 966F2, 968, VT1, Shelf type).

e) Vane relays (WSL VL1), and

f) Searchlight signal mechanisms (WSL B5, SGE LN).

Recently serviced relays are labelled with the date of their servicing.

Many existing relays are labelled with the next servicing date, which might not correspond with the current servicing frequency.

Always refer to the relay servicing program for planned replacement.

Relay shelf life is three years. Relays past this shelf life shall be tested prior to placing into service. More details on relay servicing can be found in NR/L2/SIG/11129.

14.4 Timer Relays

These are tested every 12 months to make sure that that the time setting is maintained within acceptable tolerances.

When thermal timers are tested, make sure that enough time has elapsed before repeating a relay timer test to confirm that a true reading is not affected by warm heating elements.

14.5 UPS Testing

Carry out NR/SMS/PartB/Test/057 - Clause 1.3 – This specifies testing to check that the UPS can maintain the load for 50% of the expected hold up time.

Some level crossing UPSs have a hold up time of 24 hours, which would require UPS tests lasting 12 hours.

To enable such testing to be completed within a standard working day, the following reduction has been agreed by the Level Crossings Engineer:

a) At sites with long hold up times such as Level Crossing the 50% figure quoted may be reduced to 20%.

END

Includes:	TRTS, RA, CD and TRTS Pull Wires
Excludes:	All other types of Plunger and Pull Wires

GENERAL

Platform plungers and pull wires provide indications to train crew relating to the operation of trains.

They shall only be operated by Signal Technicians with permission of the Signaller to prevent any unauthorised train movements.

Platform plungers and pull wires are usually located in an area accessible to the general public.

They shall not be left unattended in an unsecured state.

SERVICE B

1. External Inspection

1.1 Check the unit is securely mounted, clean as necessary.

1.2 Check that doors, latches, and locking devices are effective.

1.3 Check that water seals are effective.

1.4 Check that tail cables are correctly routed, secure, and not damaged.

1.5 Check and lubricate hinges, locks, and latches.

1.6 Check that external labelling is fitted, clean, and legible.

2. Internal Inspection

2.1 Check the tail cables and internal wiring are secure and correctly terminated. Protect as necessary.

2.2 Examine the insulation for damage and degradation.

2.3 Check the internal labelling is fitted, clean, and legible.

2.4 Examine the switches and plungers.

2.5 Observe, if operated by Operating Staff, that the associated indications correctly illuminate.

3. Pull Cord Assemble (TRTS Pull Cord type Only)

3.1 Examine the following on the pull cord assembly:

a) Wire and thimbles.

b) Eyelets.

c) Connection to rotary switch.

3.2 Replace the wire if it is damaged or corroded.

3.3 Examine the following on the rotary switch assembly:

a) Operating arm.

b) Spindle.

c) Switch unit fixings.

d) Connecting lug and pin.

e) Mounting bracket.

f) Cable gland.

3.4 Check that the adjustable stop is tight (two lock nuts).

3.5 Lubricate the micro-switch spindle and lug connection.

END

Includes:	Dispatch Interface Unit fitted at, London Bridge
Excludes:	All other types of Dispatch Interface Unit LED Indicators

GENERAL

Asset Identification Image

Figure 1 – Dispatch Interface Units

There are no routine maintenance services on this asset.

PERIODIC TASK

1. Replacement of the Indicator LED's

1.1 Carry out NR/SMTH/Part04/EL24 - Replace an Encapsulated LED Indicator on each off the LED Indicators.

END

Includes:	Apparatus Case, Location Cases, Relay Cabinets, Equipment Cupboards, Stump Boxes
Excludes:	Dorman integrated Lightweight Signal [iLS], Modular Signalling Equipment Housings, Ansaldo Peripheral and Temperature Controlled Locations.

Always ‘test before touch’ any Functional Supply Points and any associated metal work.

General

Check any record cards for any entries since your last visit.

Where alterations are being carried out, your SM(S) should have briefed you on the work and the effect on planned maintenance.

If you find evidence of project work that you have not been told about, contact your SM(S).

Cable Locations

Sections 1 to 3 and 7 to 10 are not required for trackside location cases which only contains cable terminations.

PERIODIC TASK ONE

For all Busbars monitored by a busbar monitoring device and maintained using the II RADAR system to remotely monitor condition.

Earth fault investigation is required as a result of an alarm.

1. Remote Maintenance

1.1 Log in to the system and search for required asset.

1.2 Confirm the location ID using Ellipse number.

1.3 Check that the Device Health status is OK, and the logger has been receiving data within the last 24 hours as a minimum.

1.4 Check that there is data available for the last 24 hours.

1.5 Check that the Earth Loop Resistance is within usual tolerance for the site (this could be a specified maximum for the site).

If any of the checks in 1.1 to 1.5 are not correct, investigate as per local processes before continuing onto the next steps.

1.6 Steps 1.1 to 1.5 shall be completed before moving to the next step.

1.7 For each busbar, check for Voltage (Vs) alarms or alerts. Where the reading falls outside of tolerance report the details to your SM(S).

NOTE: *The normal tolerance for signalling power supplies is +/- 10% of nominal voltage; variances to tolerances might be specifically authorized by the SM(S)*

1.8 For each busbar, check for Resistance alarms or alerts.

NOTE: *The II RADAR alert and alarm thresholds are set in accordance with the levels specified in NR/SMS/PartZ/Z07 – Section 3.3.*

If a Red Earth is alarming, this is below the safety minimum limit and shall be treated with high priority. Check to confirm that a fault report has been raised, if not refer to local processes of managing earth faults below the reportable limit. For any other alarms, report to your SM(S) as per local processes.

1.9 Review all Red Earth alarms, that have occurred since the last maintenance visit was undertaken, and confirm that the correct actions have been taken.

1.10 Confirm the are no alerts or alarms before moving to the next step.

1.11 Compare the values to those of the last service. Where the trend is worsening significantly from previous results, report to your SM(S).

1.12 Confirm there are no outstanding issues found in Steps 1.1 to 1.10.

1.13 Any outstanding issues shall be reported to SM(S).

SERVICE A

2. Power Supplies

2.1 Measure the power supply and busbar voltages (±10% of rating) for all signalling supplies.

Your SM(S) shall advise you if current readings are required. Current readings should only be taken if this is practical to do so.

See the notes in NR/SMS/PartC/EL00 (Electrical Equipment – General) on hazards associated with electrical supplies.

Investigate any significant variation from previous records.

3. Earth Tests

3.1 If fitted, carry out NR/SMS/PartB/Test/053 (Earth Leakage Detector (ELD) Function Test).

3.2 Investigate ELD fault indications and record any faults on the record card.

3.3 Carry out NR/SMS/PartB/Test/051 (Busbar Earth Tests) on each power supply not continually monitored (excluding earth return circuits).

3.4 Rectify any earth fault found in steps 3.1 to 3.3 that is above the reportable limit.

Report to your SM(S) the problem and any difficulties in rectifying it. Failure to rectify shall be reported to your SM(S) for necessary remedial action. The report shall be made within 24 hours.

3.5 If any earth fault is found with the voltage below the reportable voltage, NR/SMS/PartZ/Z07 (Earth Leakage – Reference Values), but the trend is worsening significantly from previous results, report to your SM(S).

Make the report within 24 hours. Your SM(S) shall decide if any further action is required.

SERVICE B

4. External Inspection

4.1 Check cases are accessible, and the doors are not obstructed.

Remove or report excessive foliage or obstructions.

4.2 Check for fire risks around the location(s) remove or report any possible risks.

4.3 Check (if provided) that any guardrails and staging are secure.

4.4 Examine case steelwork and doors for corrosion, damage, obstruction, and security.

4.5 If provided, check door seals.

4.6 Check case numbers are clearly labelled.

4.7 Check locks are fitted and in good order.

4.8 If provided, check the earthing continuity between the location(s) and the earth rod.

4.9 Check that all connections are secure, and the earth rod is secure in the ground.

In SIMIS-W areas check that the protective sleeve is in place if the earth cable passes under the track.

See the notes in NR/SMS/PartC/EL00 (Electrical Equipment – General) on earthing. Report any earthing problems as a corrective maintenance item.

4.10 Check that any safety/warning labels/signs are correctly displayed and legible.

These can include No Smoking, Wear PPE No Mobile Phones etc.

4.11 Lubricate locks and hinges.

5. Internal Inspection

5.1 Check that the location ventilation is in order. If heating is provided, check that it is switched on and working correctly.

In damp locations and where black relay bases are still fitted, it is important that the heater is working correctly.

5.2 Check site copy diagrams are available, properly stored and fit for purpose.

Submit a request for replacements as required.

Report to your SM(S) any handwritten or temporary alterations to the site copy.

5.3 Check internal equipment for signs of contamination, damage or failure.

5.4 Remove any dirt/infestation.

5.5 Check that any cable entry openings are suitably sealed to prevent rodent entry.

5.6 Check internal case fittings, racks, shelves, and backboards.

5.7 Dust equipment as necessary.

5.8 Check equipment is correctly labelled.

6. Cables, Wires and Terminations

6.1 Examine cables and wires for damage particularly in ducting and where they pass above a heater, transformer, or any other heat source. Report any damage as a corrective maintenance item.

Take immediate action on any exposed conductors. Damage includes any new wet/dry degradation. Rodent damage can occur to wiring in ducting which is not immediately visible.

6.2 Check that wire degradation signs are in place if this is present in the apparatus case.

NOTE: *The examination of cables and wires for changes in wire degradation and the related timescales are now covered by NR/L2/SIG/11655 (Management of Cable and Wire Insulation).*

6.3 Check cables are secure and free from damage/chafing/rodent damage.

Cable clamps should be fitted to check that short circuits cannot occur if the cable is pulled from outside the case.

6.4 Examine cables and cable termination points for signs of new wet or dry wire degradation.

6.5 Check cable cores for degradation and damage especially if located above a heat source.

6.6 Where applicable, check terminals for security, corrosion, arcing and risk of short circuit/disconnection. Protect 2BA/0BA terminals as necessary.

6.7 Check potheads. Examine terminations and fixings. Clean and protect as necessary.

6.8 On 2BA/0BA terminals, check that red dome nuts are fitted as required. On WAGO terminals, check that red insulation stops are fitted as required.

6.9 Check un-terminated cores or wires are correctly insulated.

6.10 Report any temporary insulated, unterminated cables and wires to the SM(S).

Un-terminated cables and wires shall only remain insulated with temporary insulation (silicon sleeves) for a maximum of 12 weeks. If not terminated, they shall be permanently insulated.

6.11 Check any ‘red straps’ that are installed are secure and labelled.

6.12 Carry out NR/SMS/PartB/Test/054 (Cable Insulation Tests) on the following lineside cables, which are not monitored by an ELD or BMD.

a) Cables containing single cut safety critical circuits.

b) Safety critical reed circuits.

c) Earth return circuits.

d) Double cut lineside cables, If not monitored by a busbar test.

The number of cores to be tested shall be, all spare cores or 10% of the cable capacity, which ever is greater.

Cable insulation testing shall be carried out at one end of the cable only.

6.13 Power Cables are managed by E&P Staff under NR/L3/SIGELP/50001.

7. Rack/Shelf Mounted Equipment

7.1 If not managed by a relay re-servicing database, check a sample of relays to see they are within their Service date. Report any missing labels to your SM(S).

Details on relay servicing which could be carried out as a separate exercise can be found in NR/SMS/PartC/EL00 (Electrical Equipment – General). Your SM(S) is to advise you.

Service track circuit relays at 10 yearly intervals.

TC relays on TI21 installations are not covered by this requirement. TC relays on other types of frequency track circuits are. See NR/L2/SIG/11129 for further details.

7.2 Examine a sample of phenolic (black) relay bases (1% or 1, whichever is greater) and contact spacers for signs of silver migration or similar contamination following removal of the relay(s).

NOTE: *Where the spades are not silver plated this task need not be carried out. If you are unsure your SM(S) will advise you if this task is required.*

Your SM(S) can tell you specific relays to be examined. Report any silver migration found. More details on relay bases can be found in NR/SMS/PartC/EL00 (Electrical Equipment – General).

7.3 Check equipment for security and signs of damage, degradation, moisture, overheating, and cover distortion.

7.4 If provided, check for oil leakage from AC track circuit capacitors.

7.5 Check relay terminal shrouds are fitted.

7.6 On Thermal Relay Timers, carry out NR/SMS/PartB/Test/061 (Relay Timer Test).

8. Local Policy Requirement 1

8.1 On Non-Thermal Timers**, c**heck the section of the NR/SMS/PartL/Index (Local Policies) for your area and carry out NR/SMS/PartB/Test/061 (Relay Timer Test) on non-thermal timer relays as directed.

8.2 Check that the seals on timer relays are crimped.

9. Data Links

9.1 Carry out NR/SMS/PartB/Test/062 (Line Protection Unit Test).

9.2 Carry out NR/SMS/PartB/Test/089 (SSI Datalink Test).

This test might not be required under certain circumstances:

a) on interfaced SSI.

b) or, when monitored remotely.

c) or, if scheduled against another work group.

Your SM(S) will advise you.

10. Power Supplies (Transformers / Rectifiers, TFU etc)

10.1 Examine earth connections.

10.2 Examine terminations.

10.3 Check for signs of overheating.

10.4 Check protective shrouding/covers are fitted and undamaged and that warning signs are correctly displayed (i.e. all equipment rated >175V).

10.5 Carry out NR/SMS/PartB/Test/053 (Earth Leakage Detector (ELD) Calibration Test.

10.6 Carry out NR/SMS/PartB/Test/052 (Dynamic Earth Tests) applicable equipment controlled by the Trackside Apparatus Case if not undertaken as part of the individual equipment SMS.

11. Final Check

11.1 Before leaving site, check that covers, doors and locks are properly fitted and secure.

END

Includes:	Equipment Rooms, Relay Rooms, Interlocking Rooms
Excludes:	Control & interface systems and associated cubicles, SSI equipment and Ansaldo equipment.

Always ‘test before touch’ any Functional Supply Points and any associated metal work.

General

Where alterations are being carried out, your SM(S) should have briefed you on the work and the effect on planned maintenance.

If you find evidence of project work that you have not been told about, contact your SM(S).

Before leaving site, check that access points are secured to prevent unauthorised access.

SERVICE A

1. General Inspection

1.1 Check and complete the site Logbook or Site Attendance Record Card.

Particular attention should be paid to any entries made since the last maintenance visit.

1.2 Check and record the equipment room temperature on arrival in the Logbook or on the Site Attendance Record Card.

The normal temperature ranges are between 15 – 20ºC.

1.3 Check (if fitted) that air conditioners (coolers) are switched on and working during the summer (April to September).

Check if they are controlled by thermostats, if they are then they should be left switched on all year round.

1.4 Check (if fitted) that heaters are switched off during the summer. If both heating and cooling are fitted and controlled by thermostats, check that the controls for this are working correctly.

Heaters and coolers should not be both on at the same time. If heating is turned on/up whilst you are working in the room, return the controls to their original setting when leaving Report any problems to your SM(S).

1.5 Report any sign of structural deterioration or forced entry to your SM(S). Check the interior roof/ceiling tiles for any signs of damp/damage.

1.6 Check for fire risks around the location and the existence of excess vegetation.

Remove or report any possible risks as a corrective maintenance item.

1.7 On portable equipment rooms check that the skirt around the bottom of the location is effective.

1.8 Check that security locks, lighting, and ventilation are in order.

1.9 Check that any safety/warning labels/signs are correctly displayed and legible.

These can include No Smoking, No Mobile Phones, Wire Degradation Classification etc.

1.10 If provided, check the earthing continuity between the signalling earth points and the earth rod. Check that all connections are secure, and the earth rod is secure in the ground.

See the notes in NR/SMS/PartC/EL00 (Electrical Equipment – General) on earthing. Report any earthing problems as a corrective maintenance item.

1.11 Remove any dirt/infestation.

1.12 Check cable entries are sealed to deter rodents, where practicable.

1.13 Check racks and equipment are secure and not damaged or contaminated.

1.14 Check site copy diagrams and (if provided) O&M manuals for electronic equipment are available and fit for purpose. Submit a request for replacements as required. Report to your SM(S) any handwritten or temporary alterations to the site copy.

1.15 Check time clock settings (e.g. AWCU). Remember BST & GMT.

1.16 Examine a sample of cables and wires for damage.

Your SM(S) can tell you which cables and wires to look at.

Immediate action shall be taken on any exposed conductors.

Damage includes any new wet/dry degradation. Rodent damage can occur to wiring in ducting which is not immediately visible.

2. Emergency Control and Technicians Indication Panels

2.1 Turn the panel on and check for the correct operation of the indications.

2.2 Check control/indication panel faceplate. In particular note and report:

a) Worn or illegible artwork.

b) Damaged panel sections.

c) Obvious faulty buttons/switches.

d) Faulty indications/lamps.

2.3 Dust and wipe panel faceplates with a cloth moistened with detergent or non-abrasive cleaner, as necessary.

2.4 Turn the panel off.

3. Power Supplies

3.1 Check warning signs are clearly displayed.

3.2 Dust and check power supply equipment.

Transformers, rectifiers, chargers, circuit breakers, fuses, links, switch-gear, bus-bars, connections etc: Investigate any signs of overheating/ arcing. Locks and latches shall be secured.

3.3 Check earth connections and cable terminations.

3.4 Check (>175V) that equipment covers, and safety labels are fitted and that rubber matting/ gauntlets are available.

3.5 Measure the power supply and busbar voltages (±10% of rating) for all signalling supplies.

Your SM(S) shall advise you if current readings are required. Current readings should only be taken if this is practical to do so.

See the notes in NR/SMS/PartC/EL00 (Electrical Equipment – General) on hazards associated with electrical supplies.

Investigate any significant variation from previous records.

3.6 Check power and standby system indications Uninterruptible Power Supplies (UPS) and Static Invertors.

3.7 Check spare fuses are available.

4. Earth Tests

4.1 If fitted carry out NR/SMS/PartB/Test/053 (ELD Function Test).

Investigate ELD fault indications and record any faults on the record card.

4.2 If an ELD is not fitted, carry out NR/SMS/PartB/Test/051 (Busbar Earth Tests) on each power supply not continually monitored (excluding earth return circuits).

4.3 Rectify any earth fault found that is above the reportable limit.

4.4 Record any faults in the site log book or record card.

Report to your SM(S) the problem and any difficulties in rectifying it. Failure to rectify shall be reported to your SM(S) for necessary remedial action. The report shall be made within 24 hours.

4.5 If any earth fault is found with the voltage below the reportable voltage NR/SMS/PartZ/Z07 (Earth Leakage – Reference Values) and the trend is worsening significantly from previous results, report to your SM(S).

The report shall be made within 24 hours. Your SM(S) shall decide if any further action is required.

5. Batteries & Cells General

5.1 Check warning signs (e.g. No Smoking) and P.P.E. signs (Goggles, Gloves etc).

5.2 Clean and examine batteries, cells, straps and terminations (use insulated box spanner).

5.3 Protect terminations as necessary.

Arrange for any defective cells to be replaced If a cell in a crate is found to be faulty, the whole crate shall be replaced.

6. Primary Cells

6.1 Check that there is ventilation over the top of the cells.

6.2 Carry out NR/SMS/PartB/Test/058 (Primary Cell Test) if required.

Continually loaded cells shall be replaced if their obtained readings indicate they could fail before the next maintenance visit. See NR/SMS/PartC/EL00 (Electrical Equipment – General).

7. Secondary Cells

7.1 Check that the correct number and type of cells along with the correct charger are fitted according to the diagram.

Changes could have been made during corrective maintenance.

More details are in NR/SMS/PartC/EL00 (Electrical Equipment – General). Report as corrective maintenance any discrepancies.

7.2 Clean and examine all exteriors and cases.

7.3 Check the level of electrolyte - top up with distilled/ionised water as necessary.

8. SSI Equipment (if applicable)

8.1 Examine the modules, connectors, cables for security and signs of overheating, arcing, or damage.

8.2 On the SIGNAL module (if fitted), observe that the following red indicators are illuminated:

a) Power.

b) System.

c) Rx data.

d) Outputs.

8.3 On the POINTS module (if fitted), observe that the following red indicators are illuminated:

a) Power.

b) System.

c) Rx Data.

d) Points X.

e) Points Y.

8.4 On the LONG DISTANCE TERMINAL, observe that the following red indicators are illuminated:

a) Power, System.

b) PCM TX Clock.

c) PCM Rx Clock.

d) PCM Rx Line.

e) Data From SSI.

f) Data To SSI.

g) Data To PCM.

8.5 On the DATA LINK module, observe that the red power indicator is illuminated.

If any of the indicators have failed but the equipment is still functioning correctly, make a note in the system logbook and inform your SM(S).

It is not necessary to renew modules for indicator faults only.

9. WESTLOCK Trackside Equipment (Zone controller) (if Applicable)

9.1 Check captive screws are tight on the PM, RSA and SOM110 Modules.

9.2 Where a 24V DC Power Module is fitted, observe that all the system "Healthy" indicators are illuminated, as follows:

Modules	Indication	Status
24 V DC Power supply	DC OK	Green Steady
24 V DC Buffer module (if Fitted)	Status	Green Steady
24 V DC Buffer module (if Fitted)	Diagnosis	Off
24 V DC Buffer module (if Fitted)	Check input Voltage	Off

Table 1 - DC Power module indications

10. Final

10.1 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

SERVICE B

11. General Inspection

11.1 Check racks, shelves, and backboards. Dust equipment as necessary.

11.2 Check equipment is correctly labelled.

11.3 Sweep the floor and clean windows if required.

12. Power Supplies

12.1 Liaise with the Signaller before interrupting power supplies.

12.2 Check power panel voltmeters and ammeters.

Most panel meters are provided for indication purposes only and where practicable the indication shall be compared with a reading on a calibrated meter.

If the power supply is disconnected for any other maintenance reason you shall make sure the needle returns to zero.

12.3 Where an alternative supply is provided (main/standby) change over the load to the alternative supply.

a) Check the standby supply takes the load, without any system failures.

b) Change load back to the main supply.

c) Check that the standby supply is available before changing over.

12.4 Carry out NR/SMS/PartB/Test/053 (Earth Leakage Detector (ELD): Testing and Calibration).

12.5 Carry out NR/SMS/PartB/Test/056 (Avel-Lindberg Static Inverter Tests).

12.6 Carry out NR/SMS/PartB/Test/057 (Uninterruptible Power Supplies (UPS) Tests.

12.7 Carry out NR/SMS/PartB/Test/052 (Dynamic Earth Tests) on applicable equipment controlled by the Equipment/Relay Room, if not undertaken as part of the individual equipment SMS.

13. Cables & Cable Terminations

13.1 Check cables are secure and free from damage/chafing/rodent damage.

Cables shall be secure enough to prevent a movement, which can lead to a short circuit.

13.2 Examine cables and cable termination points for signs of new wet or dry wire degradation.

13.3 Check cable cores for degradation and damage especially if located above a heat source.

13.4 Where applicable, check terminals for security, corrosion, arcing and risk of short circuit/ disconnection. Protect 2BA/0BA terminals as necessary.

13.5 Check pot heads. Examine terminations and fixings clean and protect as necessary.

13.6 On 2BA/0BA terminals, check that red dome nuts are fitted as required.

On WAGO terminals, check that red insulation stops are fitted as required.

13.7 Check un-terminated cores are correctly insulated.

13.8 Where cable core diversions are in place: check 'red straps' are secure and labelled.

13.9 Carry out NR/SMS/PartB/Test/054 (Cable Insulation Tests). Test lineside cables containing single cut safety critical circuits, safety critical reed circuits and earth return circuits which are not monitored by an ELD.

The number of cores to be tested shall be, all spare cores or 10% of the cable capacity, whichever is greater.

13.10 Carry out NR/SMS/PartB/Test/054 (Cable Insulation Tests). Test double cut lineside cables not monitored by a bus bar test or ELD.

The number of cores to be tested shall be, all spare cores or 10% of the cable capacity, whichever is greater.

13.11 Power Cables are managed by E&P Staff under NR/L3/SIGELP/50001.

14. Internal Wiring

NOTE: *The examination of cables and wires for changes in wire degradation and the related timescales are now covered by NR/L2/SIG/11655 (Management of Cable and Wire Insulation).*

14.1 Check wiring is correctly routed, and free from insulation damage (e.g. chafing/wire ties/rodent damage).

Wires should be physically supported in ducting and away from metal corners.

Wire lacing shall not be tight.

Plastic ties shall have the serrated edge outermost.

Ducting should be in good condition and support the wiring.

14.2 Check that un-terminated wires are correctly insulated.

15. Relays and Rack Mounted Electrical Apparatus

15.1 Check all plug-in units and rack or shelf-mounted apparatus for security and signs of damage, degradation, moisture, overheating, and cover distortion.

15.2 If not managed by a relay re-servicing database, check a sample of relays to see they are within their service date.

Report any missing labels to your SM(S).

Details on relay servicing which can be carried out as a separate exercise can be found in NR/SMS/PartC/EL00 (Electrical Equipment – General).

Track circuit relays shall be serviced at 10 yearly intervals.

TC relays on Ebitrack200 installations are not covered by this requirement, other types of frequency track circuits are. See NR/L2/SIG/11129 for further details.

15.3 Examine a sample of phenolic (black) relay bases (1% or 1, whichever is greater) and contact spacers for signs of silver migration or similar contamination following removal of the relay(s).

Your SM(S) can tell you specific relays to be examined. Report any silver migration found. More details on relay bases can be found in NR/SMS/PartC/EL00 (Electrical Equipment – General).

15.4 If provided: Check for oil leakage from AC track circuit capacitors.

15.5 If provided, carry out NR/SMS/PartB/Test/062 (Line Protection Unit Test).

15.6 If provided, test audible alarms.

15.7 Shelf Type Relays check that terminal shrouds are fitted, where necessary.

15.8 Check that the seals on timer relays are crimped.

15.9 On Thermal Relay Timers, carry out NR/SMS/PartB/Test/061 (Relay Timer Test).

16. Local Policy Requirement

16.1 On Non-Thermal Timers**, c**heck the section of the NR/SMS/PartL/Index (Local Policies) for your area and carry out NR/SMS/PartB/Test/061 (Relay Timer Test) on non-thermal timer relays as directed.

17. SSI Datalinks (if applicable)

17.1 Check the Datalink cables entering the location are securely clamped.

17.2 Check that the terminations on the line termination units and surge arrestor units are secure, including confirmation that the termination strap between 3 and 8 is in place.

17.3 If the line termination resistors are separate external units, check the resistors are present and intact.

17.4 Note the mod state of the DLMs. Mod state 1 DLMs should be phased out in all locations and immediately at where DLMs are used as back to back repeaters.

A WAIF shall be raised if Mod state 1 is found and cannot be replaced immediately.

17.5 Confirm that the actual wire length of the current loop wiring (red/white twisted) between DLMs and the associated TFM is less than 5m.

Check that the current loop wiring is secure in the cable containment and that is clear from wiring that is likely to generate noise (eg point machine controls, level crossing barrier machine feeds etc).

Where over length loops or parallelism to noise are found, inform your SMS to arrange for remedial action.

17.6 Where recent alterations have been carried out (new version of location case prints since last maintenance visit), check the location wiring diagrams to confirm that the design calls for a strap between p and k (highlighted in figure 1) on the data link module plug (unless there are two data link connections to the DLM.

If the design omits this, inform your SMS for the situation to be further investigated.

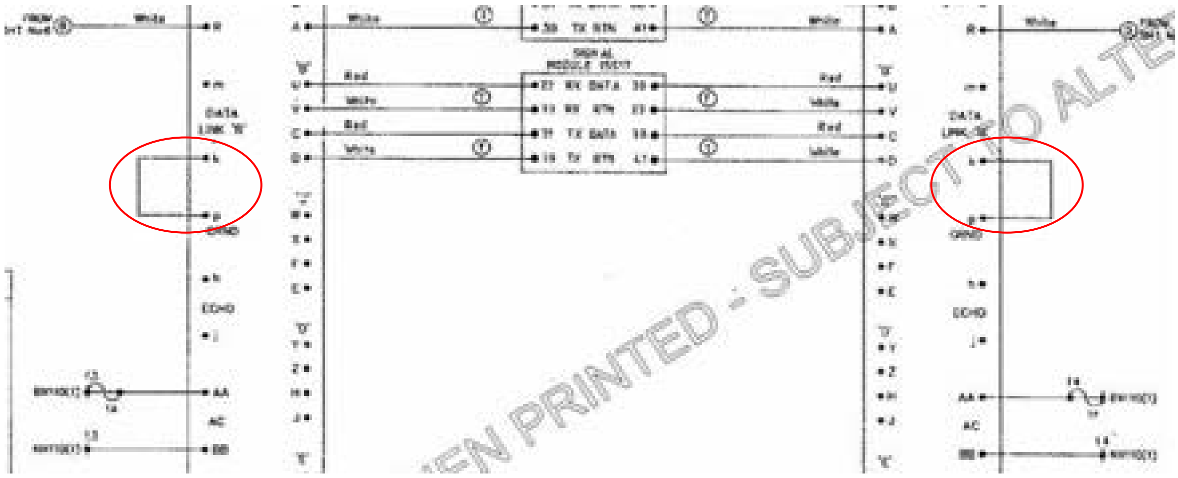

Figure 1 - SSI data link module wiring

17.7 Carry out NR/SMS/PartB/Test/062 (Line Protection Unit Test).

17.8 Carry out NR/SMS/PartB/Test/089 (SSI Datalink Test).

This test might not be required on interfaced SSI, ask your SM(S).

18. WESTLOCK Trackside Equipment (Zone Controller) (If fitted)

18.1 Remove and test each Surge Suppression Cassette using a surge Cassette Test Unit.

If the Surge Suppression Cassette fails rectify using NR/SMTH/Part04/WL07 (Replace a Siemens Zone Controller Module).

19. Lead Acid Cells (If Fitted)

19.1 Test the specific gravity on each cell is a minimum of 1.220.

Specific gravity measurements shall be taken before any top up of the cell with distilled water as this could give a false reading.

Readings below this value can indicate that the cell is reaching the end of its life and should be reported to your SM(S).

20. Secondary Cells

20.1 Carry out NR/SMS/PartB/Test/055 (Secondary Cell Test).

21. Final

21.1 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

22. Emergency Control Panel

22.1 If possible and with the operating arrangements in place, test the correct operation of the emergency panel and associated switch boxes.

NOTE: *On some routes this task is carried out by the operational staff as part of their duties, if this is the case S&T staff are not required to complete this test. If you are unsure seek clarification from your SM(S).*

Reliability Centred Maintenance

Includes:	Equipment, Relay and Interlocking Rooms with double cut lineside circuits.
Excludes:	Ansaldo Equipment cases / rooms

SERVICE RA: Carry out Service A of this SMS.

SERVICE RB: Carry out Service B of this SMS.

SERVICE RE: Carry out Service A and B of this SMS.

END

Includes:	Any electronic equipment cabinets (located in an equipment room), which do not have an associated SMS which contains cabinet maintenance as a task. Such as: ElectroloGIX.
Excludes:	Any electronic equipment cabinets (located in an equipment room), which have an associated SMS, which contains cabinet maintenance.

SERVICE B

1. Electronic Equipment Cubicles

1.1 Before working on cabinet confirm if the use of an ESD wrist strap connected to the Earth Bonding Point on the cubicle is required.

1.2 Visually confirm the cabinet earth bonding is connected and undamaged.

1.3 Clean the exterior surfaces.

1.4 Dust the interior of equipment cubicles using a dry lint free cloth.

1.5 Check (if provided) cubicle cooling fans are working, and any filters are clean. Rectify as necessary.

1.6 Visually check that all leads, panels, cards, units, fastenings, and connectors are secure and undamaged.

2. Spares (if provided)

2.1 Where no test rack facility for the system exists, check any system spares are correctly stored in anti-static bags or boxes.

2.2 Where a test rack or other functional spares assembly for the system exists, check that all the spare cards/units are correctly fitted into the rack. If requested by your SM(S), test the operation of the cards/units in the test rack.

3. Final

3.1 On completion of tasks, check that any equipment cubicle doors are securely closed and as necessary locked.

3.2 Record details of your maintenance visit and any other work undertaken in the site logbook or record card.

END

Includes:	Ansaldo signalling equipment only
Excludes:	All other types and makes of signalling equipment and associated enclosures

The infra-red light used for transmitting data in the fibre optic system is not visible. Do not look into the end of a fibre or directly into the open connectors of a fibre optic card while the card is plugged into a working system as the intensity is enough to cause permanent eye damage.

Field Isolation Unit (FIU) switches shall only be operated with the agreement of the Signaller. Lineside equipment, e.g. points, could be isolated from the Signaller's control.

Disconnecting a PC mouse from a 'live' system might disrupt the system operation.

A PC mouse shall only be replaced with the prior agreement of the responsible manager.

The affected PC shall be powered down before replacement.

A vital key board may be replaced without the need to power down the system. However, the prior agreement of the responsible manager is still required.

MSSCC AUT System, Maintenance Procedures

The majority of the equipment used in the AUT system, including the network equipment, clustered servers, and disk array is classed as specialist Information Technology equipment.

Familiarity with Windows NT, UNIX, LINUX, the tools required to manage the disk storage system and network configuration is essential.

The maintenance of the AUT System addressed in this SMS is restricted to preventative maintenance only. For further information refer to the Manchester South Signalling System O&M manuals.

REGULAR CHECKS 1

1. Interlocking/Control Rooms

1.1 Check the resistance to earth of those cables identified in Monitored Cables

More details can be found in NR/SMS/Appendix/02.

NOTE: *If a point cable is indicated as having a low insulation value the operation of the associated point heater(s) should be checked.*

1.2 Check the operating times of each set of points using maintenance terminal.

1.3 Check the life of each signal lamp using the lamp life monitoring system. Arrange replacement, as necessary. More details can be found in NR/SMS/Appendix/02.

1.4 Check the voltages of each track circuit using maintenance terminal.

1.5 Check that the event recording data is preserved.

1.6 Check the number of weekly alarms (both primary and secondary) for each data backbone and take action as required.

REGULAR CHECKS 2

2. Peripheral Location/Distributed Peripheral Location

2.1 Check the cable resistance to earth of VIO Fed Cables. More details can be found in NR/SMS/Appendix/02.

2.2 Check all the displays on 48V power supplies are operative.

2.3 Check the Field Device Controller watchdog indicators are illuminated as required.

2.4 Check the LED at each fuse holder is illuminated (rack mounted 48v DC/DC converter).

2.5 Check each fibre optic connection on fibre optic cards (vital hub, non-vital hub and FOA cards) for damage, correct connection, and minimum bend radius of optical fibre.

2.6 If applicable, NR/SMS/PartB/Test/171 (Earth Monitoring Integrity Test) Record details and results of the circuits tested.

2.7 If applicable, check the SECAP Insulation Monitor Alarms.

Alarms are monitored / displayed on the SCADA system. More details can be found in NR/SMS/Appendix/02.

2.8 Where fitted, check the temperature control thermostats and heating devices are set correctly and operative This is important especially during periods of extreme ambient temperatures.

2.9 Check all the fans in Peripheral Post modules are operative.

The Green LED adjacent to fan power supply switch indicates status of power supply not confirmation of fan operation.

2.10 Check each fan filter and clean if required.

3. Interlocking Room

3.1 Check the Interlocking Unit watchdog indicators are illuminated as required.

3.2 Check each fibre optic connection on fibre optic cards (vital hub, non-vital hub, PCs, and FOA cards) for damage, correct connection, and minimum bend radius of optical fibre.

3.3 Check the cable insulation status. Record details of any cables with deteriorating values for remedial action.

<u>AUT dedicated ELD monitoring system.</u>

3.4 Check that all the fans in Central Post are operative.

3.5 Check each fan filter. If necessary, clean as required.

3.6 Check that the thermostat in interlocking cubicle is set correctly and is operative.

3.7 Dust the keyboard(s). Hold the keyboard(s) upside down when dusting.

3.8 Clean the desk mounted VDU screen(s) in accordance with manufacturer's instructions.

3.9 Check the mouse/cursor co-ordination.

3.10 Check the ART monitor status.

4. AUT (Local Area Network (LAN) Equipment)

4.1 Check all the equipment in the LAN Rack is switched ON.

4.2 Check that all the cables are connected.

4.3 Check that each fibre optic connection on fibre optic cards for damage, correct connection, and minimum bend radius of optical fibre.

4.4 Check the green LED indications adjacent to the ports on the network hub for each item of connected equipment (AUT Servers, Communication Servers, ACC ART1 and ART2, Maintenance Terminal etc) are illuminated.

5. Maintenance Desk

5.1 Check the computer is switched ON and the keyboard and mouse are connected and working correctly.

5.2 Check the Alarm Log window is present and displays the last relevant events for the Audible Alarm.

5.3 Check that the clock corresponds with the Anthorn clock. This was formally called the 'Rugby' clock.

6. Control Room

6.1 Dust the keyboard(s). Hold the keyboard(s) upside down when dusting

6.2 Clean the desk mounted VDU screen(s) in accordance with manufacturer's instructions.

6.3 Check the mouse/cursor co-ordination.

6.4 Check the cube screens (wall display) for colour and image. Arrange remedial action as necessary. More details can be found in NR/SMS/Appendix/02.

7. AUT Desks (Primary and Secondary)

7.1 Check the workstation PC is switched on, the computer monitors are switched on, and the mouse and keyboard are connected and working correctly.

8. AUT Audible Alarms

8.1 Check that the loudspeakers on the AUT Desks are connected and switched on.

8.2 Wait for a relevant event and check the operation of the audible alarm function.

SERVICE A

9. Peripheral Location/Distributed Peripheral Location

9.1 Dust the equipment.

9.2 Check cables/connections (where accessible) and the switches on Adaptation Units.

10. Interlocking Room

10.1 Dust the equipment and Wipe glass door panels (equipment cubicles).

10.2 Clean (if necessary) monitor screens in accordance with manufacturer's instructions.

10.3 Check cables/connections (where accessible).

11. Control Room

11.1 Dust equipment.

11.2 Clean (if necessary) monitor screens in accordance with manufacturer's instructions.

11.3 Check cables/connections (where accessible).

11.4 If necessary, Wipe the cube screens (wall display) More details can be found in NR/SMS/Appendix/02.

SERVICE B

12. Peripheral Location/Distributed Peripheral Location

12.1 Carry out NR/SMS/PartB/Test/171 (Earth Monitoring Integrity Test). Record details and results of the circuits tested.

13. Stand-by Signallers Desk

Testing the standby system shall only be undertaken during engineering hours, when traffic delays are not incurred.

13.1 Check that the standby system takes over in the event of the main system shutting down.

13.2 Check associated monitoring indicator(s) are activated (if applicable).

13.3 Check associated monitoring indicator(s) are de-activated when main system is re-instated (if applicable).

14. ART and AUT Uninterruptible Power Supply (UPS)

14.1 Maintain in accordance with manufacturer's instructions.

15. External

15.1 Test the cable resistance to earth of Other Tail Cables. NR/SMS/PartB/Test/051 (Busbar Earth Tests) *or* NR/SMS/PartB/Test/054 (Cable Insulation Tests) as required.

More details can be found in NR/SMS/Appendix/02.

END

Includes:	Modular Equipment Housing (MEH), Object Controller (Axle Counter) [OC(A)], Object Controller (Interface) [OC(I)], Object Controller (Points) [OC(P)], Object Controller (Signal) [OC(S)], Feeder Pillar Power Box 1 (PB1), Power Box 2 (PB2) Power Box 3 (PB3), Axle counter Power box (PR1W) and Lockout Enclosure
Excludes:	All other types and makes of signalling equipment and associated enclosures

General

Visible light is used for transmitting data in the fibre optic system and is emitted within a tiny beam size; however, the intensity can cause permanent eye damage.

Do not look into the end of a fibre or directly into the open connectors of a fibre optic termination or use magnifying equipment to observe the light.

Anti-static precautions shall be taken when required.

It should be noted that there is no fixed lighting provided in the Lineside Compact Housings.

Further information regarding the system is available in Siemens Rail Modular Signalling Manuals.

Check any record cards for any entries since your last visit. Where alterations are being carried out, your SM(S) should have briefed you on the work and the effect on planned maintenance.

If you find evidence of project work that you have not been told about, contact your SM(S).

Before leaving site, check that access points are secured to prevent unauthorised access.

SERVICE B

1. General Maintenance

External

1.1 Check MEH, OC & PB are accessible and the door(s) are not obstructed.

1.2 Remove or report excessive foliage or obstructions as a corrective maintenance item.

1.3 Check for fire risks around the MEH, OC & PB(s). Remove or report any possible risks.

1.4 Check (if provided) that any guardrails and staging are secure. Also examine fixing bolts that secure the housing to the structure and / or foundations.

1.5 Examine MEH, OC and PB metalwork and door(s) for corrosion, damage, obstruction, and security.

1.6 Report any signs of forced entry to your SM(S).

1.7 Check lockable handle and locks are in good order and free from corrosion and damage etc.

1.8 Check the earthing continuity between the MEH, OC and PB and the earth point.

Check that all connections are secure.

1.9 See the notes in NR/SMS/PartC/EL00 (Electrical Equipment - General) on earthing. Report any earthing problems as a corrective maintenance item.

1.10 Check that any MEH, OC and PB identity numbers, safety / warning labels / signs are correctly displayed and legible.

These can include No Smoking, Wear PPE, No Mobile Phones etc.

Internal

1.11 Remove any dirt / infestation.

1.12 Check equipment is correctly labelled and that warning signs are correctly displayed (i.e. all equipment rated >175V).

1.13 Check that the silicone gasket fitted to the inside of all door(s) are free of dirt and damage and no signs of water ingress are present.

1.14 Check site copy diagrams are available, properly stored and fit for purpose.

1.15 Submit a request for replacements as required. Report to your SM(S) any handwritten or temporary alterations to the site copy.

1.16 Check equipment for signs of overheating, contamination, damage or failure.

1.17 Check MEH lighting is working correctly.

1.18 Advise your SM(S) if defective.

1.19 Check MEH thermostat is set correctly and that heating and fan are working correctly where provided.

1.20 Advise your SM(S) if defective.

1.21 Lubricate locks and hinges.

1.22 Before leaving site, check that covers, doors and locks are properly fitted and secure.

2. Technicians Facility (Local) [TF(L)]

2.1 Check the correct time and date are displayed, report to your SM(S) if this is not the case as incorrect date / time is indicative of a wider system fault.

2.2 Check the TF(L) for any outstanding faults. Rectify or report, any corrective actions required shall be logged with ICC/NRIFC.

2.3 Check that data logging is being undertaken correctly by analysis of a sample of information.

3. MEH, OC Surge Protectors, PB Surge Suppression Units

3.1 Check MEH & OC Surge Protectors are serviceable by viewing the colour of the varistor discs.

Report any failed as a corrective maintenance item.

Pink: Serviceable
Grey: Failed

Replace any failed surge protector unit immediately. Report to SM(S) any change.

Figure 1 – Surge Protector

3.2 Check PB Surge Suppression units are serviceable by viewing the colour displayed the small window.

Report any failed as a corrective maintenance item.

Green: Serviceable
Red: Failed

Figure 2 - Surge Suppression units

Replace any failed surge protector unit immediately. Report to SM(S) any change in the Indication windows.

4. Feeder Pillar

This equipment is rated at 230V AC and shall only be maintained by Technicians in areas where agreement has been reached with the E&P engineer to allow this practise.

4.1 Check the terminal cover plates, three position changeover switch MCBs are present, secure and free of damage and distortion.

4.2 Check the surge suppression unit indication windows: white indicating it is serviceable, and red when is has been subjected to a voltage surge.

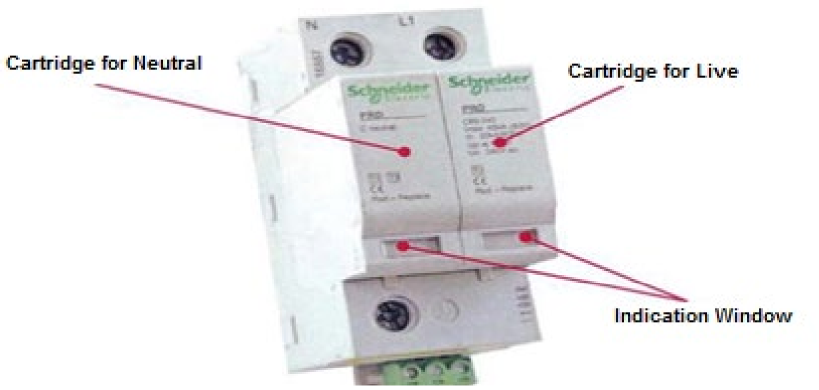

Figure 3 – MCB Units

4.3 Measure the Incoming DNO (Distribution Network Operator) voltage at the test points (Arrows A).

Measure the Incoming Gen (Generator) power supply at the test points (Arrows B), if the generator supply is in use.

Measure the Outgoing Feeder Power Supply at the test points (Arrows C). All of the voltage should fall between 207Va.c. and 234Va.c.

Figure 4 – Feeder Power Supply

NOTE: *Terminals are provided on the Feeder Pillar for measurements to be carried out. These are located behind a protective cover which shall be refitted at the end of measurements.*

5. Power Boxes [PB]

NOTE: *Terminals are provided on the PB Switch Rack for measurements to be carried out. These are located behind a protective cover which shall be refitted at the end of measurements.*

5.1 Check the terminal cover plates, power switch knobs and MCBs levers' are present, secure and free of damage and distortion.

NOTE: *in the MEH, MCBs are provided in association with barrier and other equipment and are distributed around the room. Refer to wiring details for positioning.*

5.2 Measure the power supply and busbar voltages for all equipment & logic supplies and check they are within the range as indicated in NR/SMS/PartZ (Index – Useful Values).

See the notes in NR/SMS/PartC/EL00 (Electrical Equipment – General) on hazards associated with electrical supplies Investigate any significant variation from previous records.

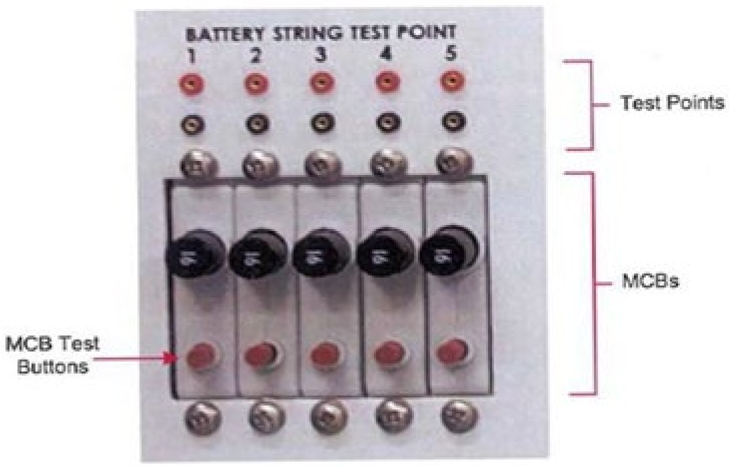
6. Power Box [PB] Battery Packs.

NOTE: *Terminals are provided on the front of the Battery Pack to enable voltage measurements to be taken.*

6.1 Check all MCBs are in their normal (fully in) position.

6.2 Press the red MCB test button and check the MCB trips. Press the black button to reset. Repeat this process for each MCB in turn.

6.3 Using the test point check each battery string has an output between 20V – 30V dc.



6.4 Repeat steps 6.1 to 6.3 for each Battery Pack.

7. Lockout devices

NOTE: *Liaison with the Signaller is required.*

7.1 Check both the switch label and local boundary diagram(s) are clean legible and secure. Clean as necessary.

7.2 Where practical, test operation of the lockout function.

a) Patrolman's lockout (LOD-P) NR/SMS/PartB/Test/174 (Patrolman's Lockout Device Test).

b) Signalling lockout (LOD-K) NR/SMS/PartB/Test/176 (Lockout Device Test).

7.3 Examine the unique key(s). Report the requirement for a replacement if worn as a corrective maintenance.

8. Audible Warning Control Unit

8.1 Check time clock settings (e.g. AWCU). Remember BST & GMT.

SERVICE C

9. Wiring and Cables

9.1 Check wiring and fibre optic patch cords are correctly routed, and free from insulation damage (e.g. kinking / chafing / wire ties / rodent damage) particularly those not in ducting and where they pass above a heat source. Report any damage as a corrective maintenance item.

Immediate action shall be taken on any damaged fibres or conductors. Damage includes any new wet/dry degradation. Rodent damage can occur to wiring in ducting which is not immediately visible.

Ducting should be in good condition and support wiring.

9.2 Check that cable entry apertures and rodent protection is intact and cables are secure by their associated clamping supports. Check cables are free from damage/ chafing/ rodent damage.

The cable clamping should be fitted such a way that short circuits cannot occur if the cable is pulled from outside.

9.3 Check that all cabling plug couplers are free from damage, secure.

NOTE: *Secure means hand tight, the use of tools to tighten the nuts on the Harting plug coupler is not allowed*

9.4 Check that all configuration plugs, logic supply, and surge arrestors are free from damage and their securing clip is engaged correctly. Also check that the seal on the addressing module is intact.

9.5 If required, examine cables and wires for changes to degradation; report any changes as a corrective maintenance item

NOTE: *To gain access to the OC(S) TPWS wiring and OC(P) relay wiring it will be necessary to remove these modules using NR SMTH test plans.*

Similarly, if you are required to inspect the wiring within a PB, access to the wiring requires the removal of all modules and isolation of the entire PB from the incoming supply. Your SM(S) will plan and advise you on either of these tasks.

More information on wire degradation can be found in NR/L2/SIG/11655.

9.6 Check that any un-terminated wires are correctly insulated.

10. Relays

10.1 If not managed by a relay re-servicing database, check a sample of relays to see they are within their service date.

10.2 Report any missing labels to your SM(S).

10.3 Check equipment for security and signs of damage, degradation, moisture, overheating, and cover distortion.

11. Final

11.1 Record details of your maintenance visit and record any other work undertaken in the site logbook or record card.

SERVICE D

12. Batteries

12.1 The batteries within the Power Boxes have an operational life and shall be replaced every 10 years.

The condition of each battery is affected by many factors but typically it is most dependent on when the battery has degraded to 80% of the manufacturers rated capacity.

END

Includes:	Ansaldo Location Case - Temperature Controlled Location (TCL)
Excludes:	All other Location Cases

PERIODIC TASK

1. External Inspection

1.1 Check TCL is accessible and the doors are not obstructed.
Remove or report excessive foliage or obstructions.

1.2 Check for fire risks around the TCL, remove or report any possible risks.

1.3 Check (if provided) that any guardrails and staging are secure.

1.4 Examine TCL and doors for corrosion, damage, obstruction, and security.

1.5 Check TCL identification number(s) are clearly labelled.

1.6 Check locks are fitted and in good order.

1.7 Remove fan cover, check the fans are free from obstruction and the fan alarm panel is operating.

2. Internal Inspection

2.1. Check on the Technician Terminal for any faults.

2.2. Check TCL for signs of contamination, damage or failure.

2.3. Remove any dirt/infestation.

2.4. Check that any cable entry openings are suitably sealed to prevent rodent entry.

2.5. Check that wire degradation signs are in place if this condition has been identified at the TCL.

2.6. Check site copy diagrams are available and properly stored.
Submit a request for replacement as required.
Report to your SM(S) any handwritten or temporary alterations to the site copy.

2.7. Replace the two air filters on the doors.

End

1. General

Logging systems are of two basic types, event loggers, and condition monitoring systems.

Event loggers log digital events such as the change of state of a relay.

Condition monitoring systems generally record measured values continuously or at predefined intervals. Hybrid systems may exist which do both types of logging. Further details of condition monitoring are given in Appendix A.

2. Time Setting

If the system time on a logger used for event logging is more than 5 minutes out, it shall be corrected.

The displayed time on all recorders or loggers should always be set to GMT (Greenwich Mean Time).

This can also be called UTC (Universal Time Constant).

Note that if the time system is controlled by the Anthorn (formally Rugby) transmitter, alterations to the time along with setting to GMT in BST periods will not be possible.

3. Sites with Remote Access

At sites with remote access the A Service is un-necessary provided that the system time and event logging are checked at least quarterly.

The system time shall be verified to within 5 minutes of the correct time, noting that this may be BST or GMT. Logging of data shall also be checked, either manually or by automated programme, by downloading the last hour’s data and confirming that the logger is logging.

4. Passwords

These are usually required for interrogating a logger. Area Technical Support may assist with lost passwords.

5. Records of Adjustments

Records should be made in the site log book of required adjustments to time or other system parameters that, if repeated and excessive, might indicate the need for system overhaul. Any such trend should be reported to your SM(S).

APPENDIX A - Condition Monitoring Equipment

1. Definitions

Indirect Measurement:	Measurement acquired without direct electrical contact e.g. using a current clamp.
Instrumentation Engineering:	The methodology for the use of monitoring and test equipment as specified in NR/GI/U033 (Use of monitoring and test equipment).

2. General

Condition monitoring equipment acquires data from on-track and lineside assets and may include a combination of analogue, serial and digital data sources. Measurements are acquired by indirect measurement and follow Instrumentation Engineering methodology.

One or more of the following methods can be used:

a) Analogue measurements acquired from sensors, e.g., current transducers; the default input range for analogue inputs is 4 to 20mA.

b) Serial data streamed from diagnostic ports e.g., RS232 or RS485.

c) Digital state monitoring, e.g., spare contacts of signalling relays.

The data acquired from the inputs is processed by the data collection unit (DCU) and transmitted to the remote server either by the mobile network using an internal modem and external antenna or the Fixed Telecom Network via an Ethernet port. Received data is processed and stored by the monitoring system and provides a record of recent and historical asset condition.

Server end functionality includes:

a) Display and trending of asset data.

b) Alarms and alerts when assets operate out of tolerance.

Approved types of DCUs are typically designed to mount into the space of a BR930 style relay to enable fitment into standard signalling equipment racks and are approved to be powered directly from 110Vac signalling supplies.

The devices require to be configured to correctly to acquire data and to communicate to the remote server; further information regarding configuration may be found within the Manufacturers’ User Manuals. See appendix B to E for further information regarding approved types of DCU.

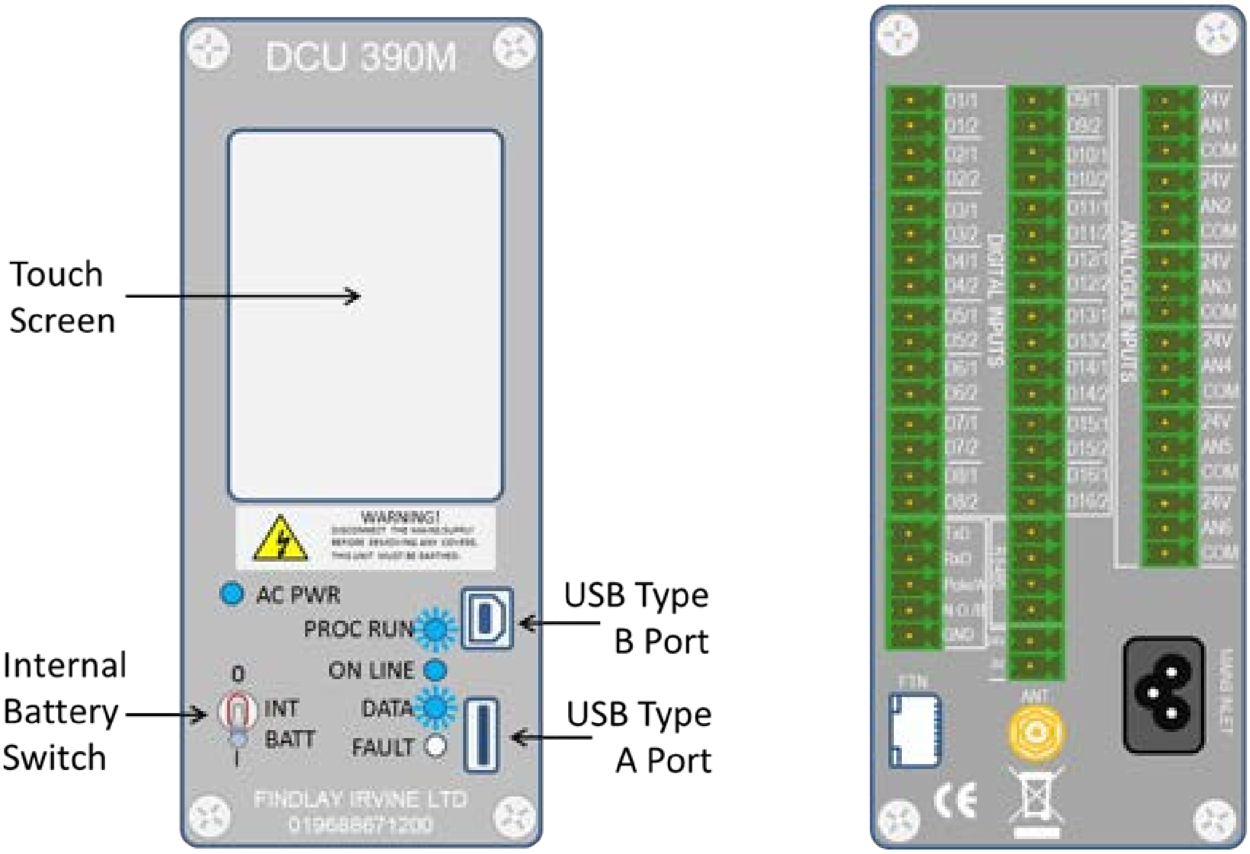
3. Maintenance Requirements

DCUs are designed to require minimal maintenance and should be replaced on failure only*. However, Technicians should take the opportunity to check device indications and dust / clean as the opportunity arises e.g., during routine maintenance of the equipment rooms and housings.

*Failure is indicated by a 'heart-beat' alarm raising in the monitoring system when a device does not communicate for an extended period, typically 6 hours.

Where condition monitoring equipment is powered from a secured power supply (e.g.110Vac derived from 650Vac supply) internal batteries, where fitted, are not critical to normal operation and do not require be routinely tested or renewed. By exception, where the monitoring application specifically requires a standby power source, special arrangements shall be required to periodically test the standby or to replace batteries following the manufacturer's instructions.

APPENDIX B - Findlay Irvine DCU390M



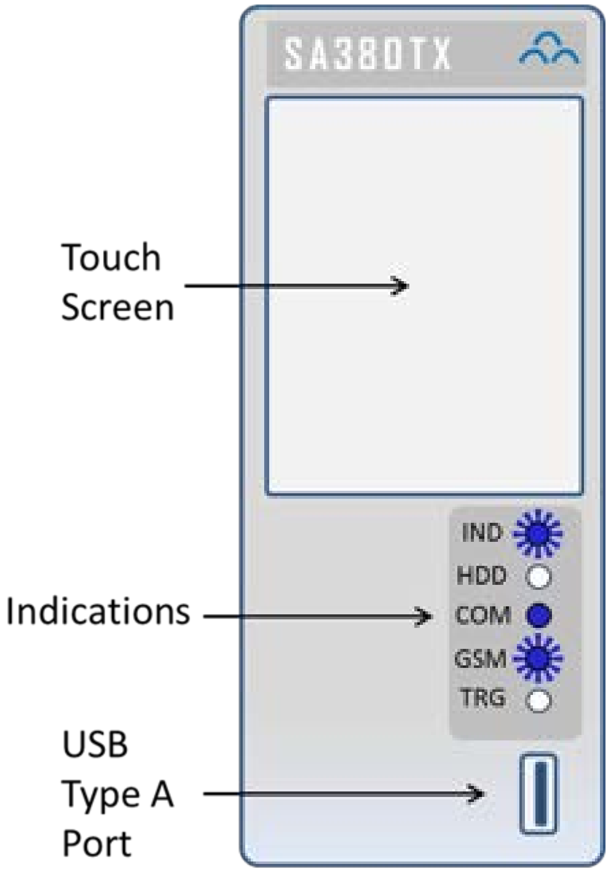
DCU 390M-Front **DCU 390M-Rear**

Figure 1 - DCU 390M Unit

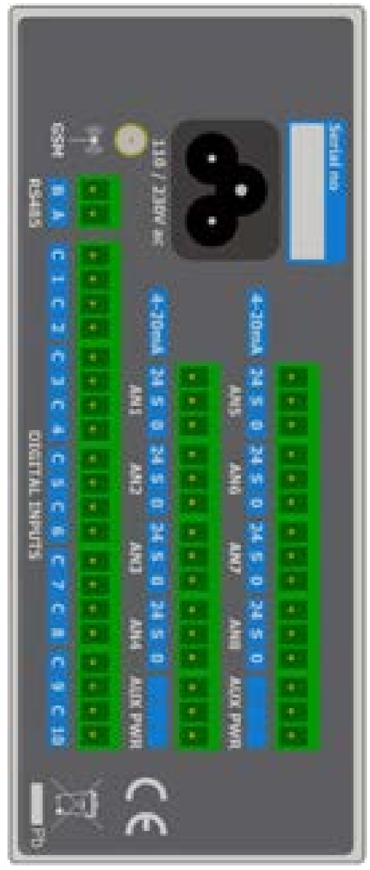
Findlay Irvine DCU 390M Normal Indications		
LED	Normal Indication	Description
AC PWR	ON	Indicates unit is correctly powered from AC Supply
PROC RUN	FLASHING	DCU main processor running correctly
ON LINE	ON	Unit connected to II via GPRS or FTN
DATA	INTERMITTENT	Lit when data acquired from inputs (Digital Signal Processor)
FAULT	OFF	Lit in the event a Digital Signal Processor Fault is detected

Table 1 – Indication Meanings

APPENDIX C - MPEC 380TX



MPEC 380TX Front



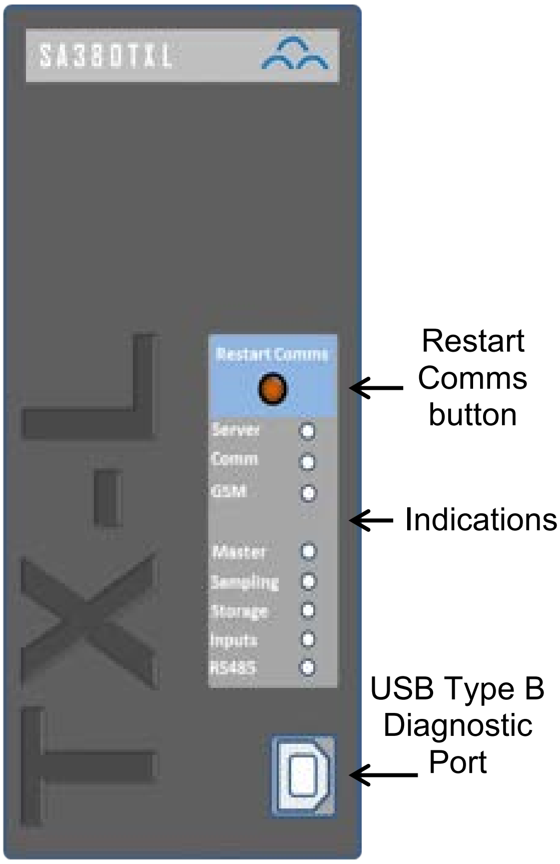
MPEC 380TX Rear

Figure 2 - MPEC 380TX Unit

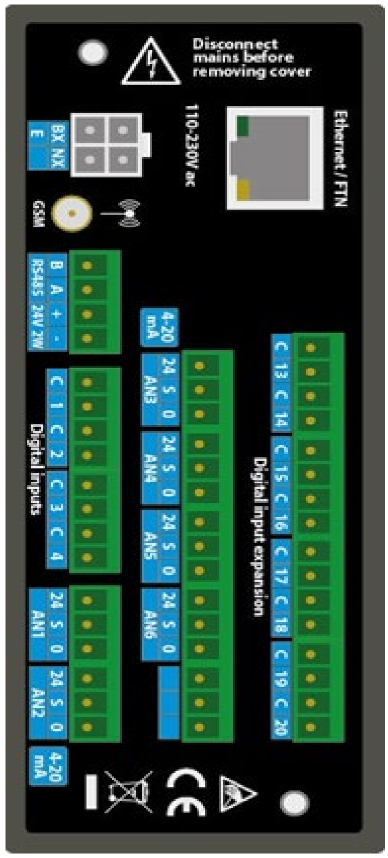
MPEC 380TX Normal Indications		
LED	Normal Indication	Description
IND	FLASHING	Indicates unit processor is running correctly
HDD	INTERMITENT	Lit with Hard Drive Activity
COM	ON	Lit when unit is connected to Remote Server
GSM	FLASHING	Flashes when connected to local network
TRG	INTERMITENT	Lit when a data event is being recorded

Table 2 - Indication Meanings

APPENDIX D - MPEC TX-L



MPEC TX-L Front



MPEC TX-L Rear

Figure 3 - MPEC TX-L Unit

TX-L Logger Normal Indications		
LED	Normal Indication	Description
Server	Steady On	Connected to the Central Data Server
Comm	Steady On	Connected to the GSM Network
GSM	Steady On	Modem Powered On
Master	Slow Flash (1 sec)	Device Operating Normally. (Fast flash 0.25s, Steady On or Off indicates processor fault)
Sampling	Intermittent Blink	Data processing activity
Storage	Intermittent Blink	Data Read / Write from database
Input	Intermittent Blink	Analogue or Digital Input change detected
RS485	Intermittent Blink	Data transmit / receive on RS485 port

Table 3 - Indication Meanings

APPENDIX E - ATLAS MINI-LOGGER

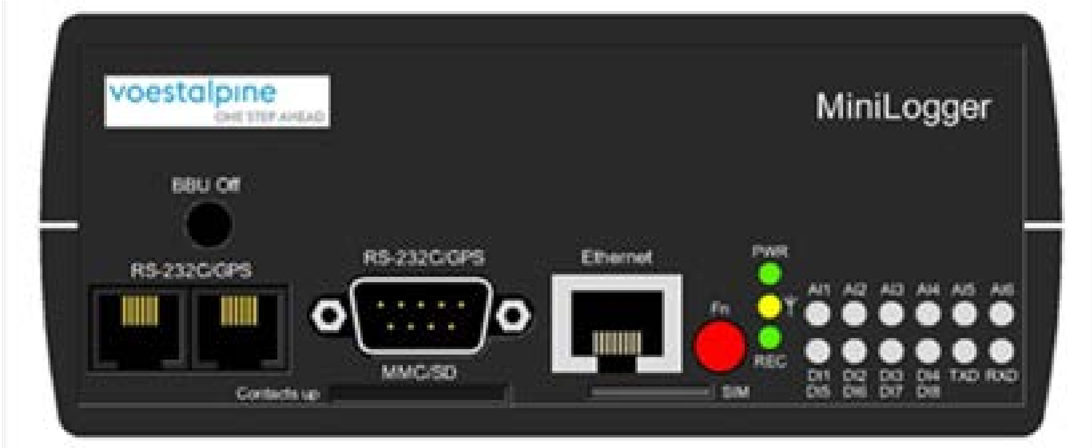


Figure 4 - Atlas Mini-Logger Front #

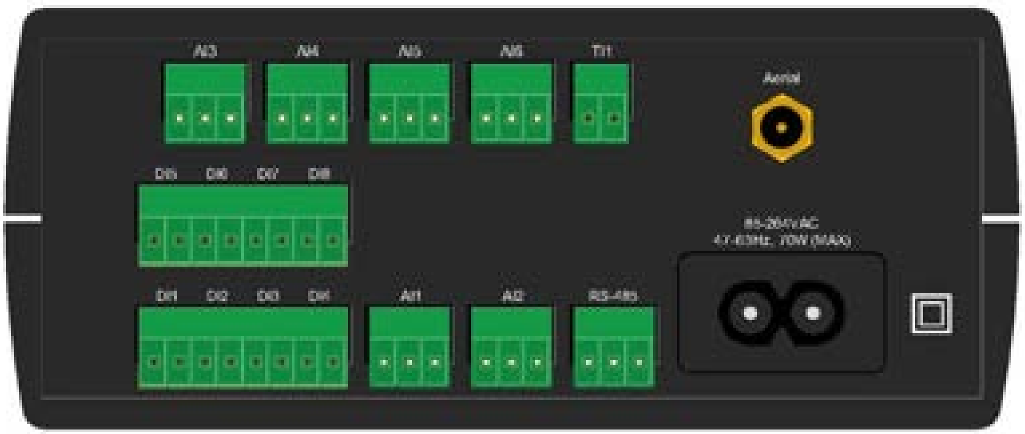

Figure 5 - Atlas Mini-Logger Rear #

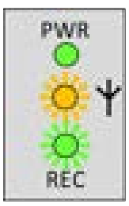
NOTE: *#The device shown is typical example of the Atlas Mini-Logger. Variant models are in use with different arrangements of inputs and indications; however, the basic functionality of devices is similar.*



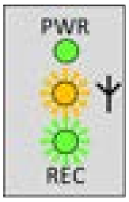
Atlas Mini-Logger Normal Indications		
LED	Normal Indication	Description
PWR	ON	Indicates the unit is powered correctly from an AC source
ANTENNA	FLASHING	Correctly connected to remote server
REC	FLASHING	Unit is logging data correctly

Table 4 - Normal Indications

APPENDIX F - MINI-LOGGER – 2

Figure 6 – ATLAS MINI-LOGGER – 2 FRONT

Figure 7 – ATLAS MINI-LOGGER – 2 REAR



Atlas Mini-Logger - 2 Normal Indications		
LED	Normal Indication	Description
PWR	ON	Indicates the unit is powered correctly
ANTENNA	FLASHING	GPRS/3G Status LED to indicate • Off = Modem Powered Off • On = Modem on, not registered onto the network • Slow flash = Modem on, registered onto the network • Quick flash = Modem on, registered onto the network and communications in progress
REC	ON	Unit is logging data correctly (LED will flash when data is stored to the internal SD card)

Table 5 – Normal Indications

APPENDIX G - RML6

Figure 8 – RML6 Front

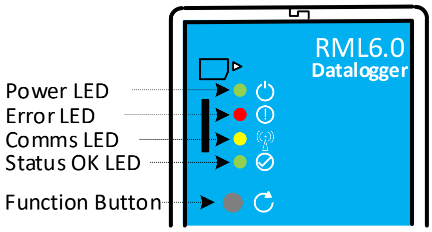


Figure 9 – RML6 LED Explanations

Figure 10 – RML6 Rear

RML6 - Normal Indications		
LED	Normal Indication	Description
PWR	ON	Indicates the unit is powered correctly
Error	OFF	Indicates the unit is operating normally and no error detected by the RML6 (LED is lit when an error is detected)
COMMS	FLASHING	GPRS/4G Status LED to indicate • Off = Modem Powered Off • On = Modem on, not registered onto the network • Slow flash = Modem on, registered onto the network • Quick flash = Modem on, registered onto the network and communications in progress
STATUS	ON	Unit is logging data correctly (LED will flash when data is stored to the internal SD card)

Table 6 – Normal Indications

END

Includes:	Instead 3, Instead 64, Instead 64 Active
Excludes:	All other types of Instead Event Recorder

General

Record any work undertaken on the record card or site log book.

SERVICE A

1. Visual Checks

1.1 Check that the 'Recording' indication is flashing and the fault indication light is not lit.

1.2 Check the displayed time and date are correct. Note that the time is always stated in GMT

SERVICE B

2. Full Test

2.1 Dust the top of the unit and wipe the clear front panel.

2.2 Run the self-test routine, observe that there are no faults indicated.

2.3 Remove the floppy disk from the unit. Using the special cleaning disk provided, run the disk drive cleaning routine. Remove the cleaning disk when completed.

2.4 Check the removed disk on a computer using the 'Instead/Sentinel' office software.

Check all functions operating correctly.

This may be done on site or alternatively the disk can be returned to a central office for this operation.

2.5 If the disk has been interrogated on site, replace it back into the unit. If the disk is to be removed from site for interrogation, insert a blank formatted 720kB disk into the unit (On the Instead 64 Active use a formatted 1.4MB disk).

Check that both disks are marked with the site name, the date and time of removal is marked on the recovered disk and the date and time of installation are marked on the new disk. Check that recording continues on the new disk.

2.6 Record the work done on the event recorder record card or the site logbook.

PERIODIC TASKS

3. Battery Replacement

3.1 Replace the unit's internal 'Cyclon' battery pack.

NOTE: *The battery pack replacement is a workshop job that will require temporary removal from site. See details in NR/SMS/PartC/ER00 (Logging Systems - General).*

3.2 Replace the unit's internal dry battery used for backup of the clock. Reset the time and date (time to GMT).

END

Includes:	Westrex signaling event recorder

SERVICE A

1 Westrix Host Logger Equipment Cubicle

1.1 Visually check the integrity of all connections.

1.2 Check that green 'Power ON' LED indicators on both logger PCs are illuminated.

1.3 Check Radio clock module status using its LCD setup/diagnostic panel.

1.4 Close Host Logger Equipment Cubicle door.

2 Westrix S3 Baseplates

2.1 Electro-static precautions shall be observed where physical contact with S3 equipment can occur.

2.2 Visually check the integrity of all connections.

2.3 Check that the operational status LED indicator displayed on each S3 module is as follows:-

- Power Supply Module (FPS400-24) green
- Data Input Module (DIP-1) green
- Scanner Module (Scanner-1) green

3 Westrix Technicians Terminal

3.1 Visually check the integrity of all connections.

3.2 Power up monitor screen and Check monitor and keyboard for correct operation.

3.3 Investigate and clear any outstanding fault messages.

3.4 Power down monitor screen.

SERVICE B

4 Equipment Cleaning and Inspection

4.1 Clean Technicians Terminal monitor and housing using a proprietary dry anti-static screen cleaner.

4.2 Check that the Technicians Terminal PC cooling vents are clear and its internal fan is operating quietly.

4.3 Clean Host Logger Equipment Cubicle door with a dry lint free cloth with door closed.

4.4 Check that Host Logger PC cooling vents are clear and internal fans are operating quietly.

4.5 Carefully dust the interior faceplates and blanking panels with a dry lint free cloth.

4.6 Close Host Logger Equipment Cubicle door.

5 Periodical Tasks

Technical support staff and/or equipment specialists could manage these tasks separately.

5.1 Replace each Host Logger PC hard disk drive (HD) with a new HD of the same, or a compatible, type.

5.2 Service/replace Host Logger PC cooling fans.

5.3 Replace Host Logger PC Lithium ion coin cell.

5.4 Service/replace Technicians Terminal PC cooling fans.

5.5 Replace Technicians Terminal PC Lithium ion coin cell.

END

Includes:	Alpha and IMP based Portable Loggers and Interlocking Monitoring Systems
Excludes:	

General

Renewed USB sticks will be automatically formatted by the standard Windows 2000 or Windows XP operating system, they will operate regardless of capacity but their size must be sufficient for the site concerned. Record any work undertaken on the appropriate record card or site log book

SERVICE A

1. Visual Checks

1.1 Alpha based systems only

Check that the Alpha Units LED indicators are illuminated
Power steady and RS485 flashing.

1.2 IMP based systems only

Check that the Solartron IMP LED indicators are illuminated for correct operation
Power illuminated but no other LED illuminated.

1.3 Check correct time is displayed. Note that the time is always stated in GMT

1.4 Open the most recent hour of data and verify that logged functions are being recorded.

SERVICE B

2. All Units

2.1 Clean all external surfaces using a lint free cloth and a mild detergent. Do not use any solvents.

2.2 Check the integrity of input connections by checking they are connected and secure.

3. Interlocking Monitoring System

3.1 Check that the processor and rack fans are clear of obstructions and dust that may restrict the airflow, and are running correctly, Rectify as necessary. Clean filters as necessary.

3.2 Carry out the UNINTERRUPTIBLE POWER SUPPLY TESTS (057))

4. Portable Logger

4.1 Check the hard disk for sufficient space until the next 'Service B', archive the old data and then delete the relevant directories to free up space as necessary. For Interlocking Monitoring Systems and Portable Loggers with the full interlocking software, at the end of each year at 2 Minutes after midnight a new year's set of files are automatically created. For other ACIC Portables these will have to be created manually.

4.2 Check modem for correct operation by dialling in.
This may be done visually on modems with LED indicators, accessed by removing the back panel.

A slow flashing LED indicates normal (modem not in use), a fast flashing LED indicates modem connected and a continually illuminated LED means no service available.

PERIODIC TASKS

5. Battery Replacement (All Systems)

5.1 Release 4 screws securing the back facing panel to gain access to Motherboard and replace the lithium cell.
This task must only be carried out when the system is isolated from the equipment it is monitoring.

The battery type is CR2032.
This should also be carried out if the clock display loses time or there is a BIOS failure.

6 Associated UPS System (Where Fitted)

6.1 Replace the batteries in the associated UPS system The UPS documentation will give the suggested periodicity for replacement.

6.2 Carry out the UNINTERRUPTIBLE POWER SUPPLY TESTS (057).

End of Periodic Task

Reliability - Centred Maintenance

SERVICE RE Carry out service A and B of this SMS

End

Includes:	Alpha 933 and Solartron IMP based Wall Mounted and Rack Mounted Event Loggers
Excludes:	All other logger types

General

Renewed USB sticks will be automatically formatted by the standard Windows 2000 or Windows XP operating system, they will operate regardless of capacity but their size must be sufficient for the site concerned. *Record* any work undertaken on the appropriate record card or site log book

REGULAR CHECKS

1. System logging

1.1 At sites with remote access and as locally agreed, either manually or by automated programme, download the last hour's data and check that the logger is logging.

SERVICE A

2. Visual Checks

2.1 Alpha 933 based systems only

Check that the Alpha Units LED indicators are illuminated.

Power steady and RS485 flashing.

2.2 Solartron IMP based systems only

Check that the Solartron IMP LED indicators are illuminated for correct operation.

Power illuminated but no other LED illuminated.

2.3 Check the correct time is displayed. Note that the time is always stated in GMT

2.4 Open the most recent hour of data and verify that logged functions are being recorded.

SERVICE B

3. Clean and Visual Inspection

3.1 Clean all external surfaces using a lint free cloth and a mild detergent. Do not use any solvents.

3.2 Check the cabinet earth bonding is secure at the Door, Cabinet Side, Side Panels (Rack Mounted system only), Rear Mounting Plate, and Gland Plate.
Visually check the integrity of connections.

4. PC Case Fan/Filter

4.1 Remove the front panel fan cover and Check that the PC fan is running. Rectify as necessary. Replace both the fan and filter unit together.

4.2 If the fan was not replaced, remove the filter cover and either Clean (plastic bubble type) or fit a new filter.

4.3 UNINTERRUPTIBLE POWER SUPPLY TESTS (057).

PERIODIC TASKS

The following tasks are to be carried out by suitably competent staff. These tasks must be carried out when the PC has been fully disconnected.

5. Motherboard CPU & PSU Fans & Battery Replacement

5.1 Remove the 6 securing screws and remove the PC cover to access the motherboard.

5.2 Replace the following:

- CPU heat sink fan.
- The fan in the rear of the PC PSU
- The lithium battery cell.
- See CD containing PC manual for type.

6 Associated UPS System (Where Fitted)

6.1 Replace the batteries in the associated UPS system The UPS documentation will give the suggested periodicity for replacement.

6.2 Carry out UNINTERRUPTIBLE POWER SUPPLY TESTS (057).

End of Periodic Task

Reliability - Centred Maintenance

SERVICE RE Carry out service A and B of this SMS

End

GENERAL

Detailed instructions for this recorder are provided in the user manual that is supplied with each recorder.

Record any work undertaken on the appropriate record card or site logbook.

SERVICE A

1. System Operation

Service A may be carried out remotely if the facility is available.

NOTE: *Touching the logger front screen will cause the display to light.*

1.1 Check that the time shown is correct.

NOTE: *the time is always stated in GMT.*

1.2 Open the most recent hour of data using the touchscreen and verify that logged functions are being recorded.

SERVICE B

2. Inspection and Test

2.1 Check that all logger cable connectors are pushed fully home, and that the logger housing is secure.

2.2 Carry out NR/SMS/PartB/Test/057 (Uninterruptible Power Supplies Test).

NOTE: *Where no external UPS is provided, the test period should be a maximum of three hours.*

PERIODIC TASKS

3. UPS System (Where Fitted)

3.1 Replace the batteries in the associated UPS system.

NOTE: *The UPS will need to be placed in by-pass and the batteries isolated from the supply.*

The UPS documentation will give the suggested periodicity for replacement.

3.2 Carry out NR/SMS/PartB/Test/057 (Uninterruptible Power Supplies Test).

4. Internal Inspection & Battery Replacement

These tasks are to be carried out by the manufacturer or a servicing agent approved by the manufacturer.

These tasks should only be carried out when the logger has been fully disconnected.

4.1 Replace the internal battery in accordance with the manufacturer's procedure.

4.2 Fully inspect and functionally test the logger in accordance with the manufacturer's procedure.

SERVICE RE Carry out service A and B of this SMS.

END

Includes:	DOS based Trackwatch Max, Trackwatch LX & Trackwatch Lite systems that use IMPs to collect digital event data
Excludes:	Windows based and Atlas Technology based Trackwatch products

Anti-static precautions are required when working on the Trackwatch Controller Internal Circuitry.

General

This system uses Solartron IMP units to interface with signalling functions and gather data, which is then forwarded to the Trackwatch Controller using an S-Net connecting system. The Trackwatch Controller provides time, date, and storage for the logged data, and has facilities for local and remote interrogation and retrieval. Certain systems may have Modbus devices connected as well as or instead of IMPs, for maintenance of these refer to manufacturer's documentation.
Record any work undertaken on the appropriate record card or site log book.

Equipment

A suitable multimeter and portable VDU and keyboard or laptop PC with pc anywhere installed (and on logger) are required.

SERVICE A

1. UPS & IMPs

1.1 Check the LEDs on the IMP units are lit as appropriate for normal working, note that the Power LED should always be lit, investigate and rectify as required.

SERVICE B

2. Trackwatch Controller

2.1 Connect VDU to the output socket at rear of Trackwatch Controller. Connect the portable VDU and keyboard or laptop PC to the Trackwatch Controller.

This provides either an 110V isolated supply (no other 110V supply is to be used) or 230V.

A cross-over Ethernet cable must be used.

2.2 Investigate and rectify any faults indicated in upper window of display.
Note that some faults may need to be dealt with at the next task, when logging is stopped.

2.3 At sites not implementing Service A, stop the logging and inspect the last hour's data and system health file to check the logger is working correctly.

2.4 Enter directory C:\EVA and use DOS commands to copy the entire directory to the floppy disk, Check the floppy disk now has the directory.

2.5 Delete the Watchdog log file and Check that the hard disk has sufficient spare capacity for all data up to the next Service B, if in doubt ask your SSM.

2.6 This task should be performed only If the system is running slow or there are system performance issues:

Run DOS commands 'SCANDISK' then 'DEFRAG' and Record any bad sectors in the log book.

2.7 Check the system date & time by entering directory C:\ALTAIR and running the command 'TIME'.

Note that the time is always stated in GMT

2.8 Test the system Watchdog by exiting the program and leaving it running at "Exit Yes/No" screen. Time the system to check that it automatically reboots in under two minutes.

2.9 Replace the floppy disk, labelling the removed one and returning it to your SSM.

2.10 Restart the Trackwatch Controller and check the screen for error messages, press F6 for a health check, before removing the portable VDU and keyboard or laptop PC.

2.11 Check that main fan is rotating.

3. Equipment Cubicle

3.1 Clean the air intake filters and check any air vents are clear of any obstructions.

3.2 Clean the cubicle exterior with a suitable non- abrasive cleaner.

3.3 Dust the cubicle interior with a dry lint free cloth.

3.4 Where provided, Carry out the UNINTERRUPTIBLE POWER SUPPLY TESTS (057).

3.5 Visually Check cables and connections.

4. System Filters

4.1 Switch off Trackwatch Controller.

4.2 Replace filter gauze at the front of the Trackwatch Controller with manufacturers approved part

TN6 type uses RS part number 184-5141.

4.3 Using an air duster, Clean the power supply grid at the rear of the Trackwatch Controller.

4.4 Switch on Trackwatch Controller.

PERIODIC TASKS

5. Trackwatch Controller Internal Circuitry

5.1 Switch off Trackwatch Controller, then disconnect, and remove it from cabinet or other housing.

5.2 In a suitable workshop environment with electrostatic protection remove outer case.

5.3 Blow away any dust that has built up on the circuit boards with an air duster.

5.4 Replace processor cooling fan.

5.5 Replace system internal battery (5 yearly).

5.6 Refit outer case.

5.7 Refit in cabinet and reconnect all cabling, fit portable VDU and keyboard.

5.8 Switch Trackwatch Controller on and Observe the start-up routine.

5.9 Investigate any error messages and Rectify.

5.10 Remove portable VDU and keyboard.

6. Associated UPS System (Where Fitted)

6.1 Replace the batteries in the associated UPS system
The UPS documentation will give the suggested periodicity for replacement

6.2 Carry out the UNINTERRUPTIBLE POWER SUPPLY TESTS (057).

End of Periodic Task

Reliability - Centred Maintenance

SERVICE RE Carry out service A and B of this SMS

END

Includes:	Any Voestalpine, Atlas system including the Mini logger, Mini logger 2 & RML6 used for logging data acquired through digital, analogue, or serial interfaces
Excludes:	External equipment such as sensors, cabling, and isolation devices

General

Atlas, logging systems can be configured to log digital and analogue functions, and combinations of these. There are several models to accommodate different numbers of monitoring channels and asset types. Table 1 places these types into three categories:

Logger Description	**Category**
PC card rack-based system (Atlas)	Rack Atlas Systems
Mini Logger: Lite, Serial, Analogue, Plus, VTI, HVI	Legacy Mini loggers
Mini Logger 2 & RML6	Web based Loggers

Table 1 – Logger Categories

The sensors used by analogue systems, and any cabling, fastenings and external isolation required to connect such sensors, are subject to separate and additional maintenance requirements.

Test Equipment (Atlas – Rack Atlas) & (Legacy mini loggers)

A multi-meter and laptop computer with a terminal emulator.

Test Equipment (Web based)

A multi-meter and laptop computer with a compatible web page browser.

SERVICE A

1. Visual Checks (Atlas – Rack Atlas) & (Legacy mini loggers)

1.1 Observe that all indications are illuminated for normal working.

NOTE: *Rack Atlas and Mini Loggers channels indications need to be triggered to turn on its indications.*

1.2 Check Rack Atlas display for error messages and for correct time.

NOTE: *The time is always stated in GMT.*

1.3 Open the most recent hour of data and verify that logged functions are being recorded.

Mini Logger Only (Legacy mini loggers)

1.4 Visually check that the system and its connections are suitably secured to prevent accidental electrical contact with other signalling systems.

2. Visual Checks (Web based loggers)

2.1 Observe that all indications are illuminated for normal working.

2.2 Visually check that the system and its connections are secured to prevent accidental electrical contact with other signalling systems.

SERVICE B

NOTE: *The tasks in this service are optional for the Mini Logger connected to a central server.*

3. Interrogation of System (Atlas – Rack Atlas) & (Legacy mini loggers)

3.1 Connect the PC to the Atlas using either the Ethernet or Null modem connections and run 'Hyper-Terminal' to establish a valid connection.

NOTE: *The Ethernet cable must be of the 'cross-over' type.*

3.2 Log on to the Atlas using your password.

3.3 Type the word 'STAT' and press the return key. Rectify any faults indicated in the PC display.

3.4 Check that any media cards are installed in the Atlas using the PC on-screen menu.

3.5 Remove the media card from the front of the Atlas. Push the card into the slot and release.

It should pop up sufficiently to enable removal.

3.6 Insert the media card into the PC and copy the contents to the laptop memory, then check for correct copying.

3.7 Refit the media card in the Atlas.

NOTE: *When the media card is re-inserted, the logger may start to bleep. This indicates the internal and external cards are syncing data. This bleeping will cease once both cards have the same data. Some newer style loggers only have one internal media card. Steps 3.5 to 3.7 can be ignored in this case.*

3.8 Log off from the Atlas logger and disconnect the PC.

3.9 Check the Atlas display for error messages and rectify any faults identified.

4. Interrogation of System (Mini Logger 2 & RML6)

4.1 Connect the PC to the Mini logger or RML6 using an Ethernet Cable and open a web page using the integral IP address 169.254.201.100 to establish a valid connection.

4.2 Select “Mini Logger Status” from the web page menu.

4.3 Rectify any faults indicated on the web page.

4.4 Click on the Voestalpine Logo to return to the menu.

4.5 Select “Mini Logger Diagnostics” and check the Loggers Date and Time, using the tab on the web page. Correct if needed.

You are prompted for your Voestalpine Password.

NOTE: *Passwords can be obtained from the user manual or your local Technical Support.*

5. System Cubicle or Housing

NOTE: *This section is not applicable to the Mini Logger*

5.1 Check the air vents are clear of any obstructions, clean or renew any filters as necessary.

5.2 Clean cubicle exterior with a suitable non-abrasive cleaner.

5.3 Dust cubicle interior with a dry lint free cloth.

6. Power and Connections

6.1 Carry out the NR/SMS/PartB/Test/057 (Uninterruptible Power Supplies Test).

6.2 Visually check all cables and connections are secure.

7. PERIODIC TESTS

7.1 Using eye protection, remove the Atlas from housing, open system cover and using an air duster carefully blow away any dust from the interior.

7.2 Replace the system internal battery.

7.3 Re-fit system cover and secure with screws, re-fit Atlas into housing and secure.

7.4 Reconnect all associated cabling, attach screen and keyboard, and switch the system on.

7.5 Observe the start-up routine and check that the program is launched using the system Autoexec file.

7.6 Observe the system messages at the top of the screen; Check that no system errors occur during boot-up.

7.7 Remove the screen and keyboard

End of Periodic Task

Reliability - Centred Maintenance

SERVICE RE Carry out service A and B of this SMS.

END

Includes:	Balfour Beatty Rail Ltd. Relay^{ALERT} data logging system
Exclude:	All other logging/event recording systems

Take anti-static precautions when working on the RelayALERT Data Logging System.

General

Detailed instructions for this data logger can be found within the user manual provided at each site where a logger has been installed. System icons can be found in Appendix A.

Relay^{ALERT} data logging systems can be configured to log digital functions. There are two sizes of housing to accommodate different numbers of monitoring channels. A master Relay^{ALERT} alongside a maximum of 7 slave data loggers can be configured to measure a total of 3072 channels.

SERVICE B

1. System Operation

The checks specified in this section are only applicable to the Relay^{ALERT} master logger unless the slave is specifically referenced. Where there is a single data logger present, consider this unit to be the master.

1.1 Touch logger screen to illuminate then proceed with the tests listed below.

1.2 Functions being logged by the data logger should appear on the screen of the master data logger as they change state.

NOTE: where one or more slave loggers have been installed, the functions being logged by these will also appear on the screen of the master logger.

1.3 Check the correct time is displayed along the bottom of the screen.

NOTE: the time is always displayed in UTC.

1.4 Open the most recent hour of data and check that logged functions have been recorded.

1.5 To check the ability to retrieve data from the external storage:

a. Click remove memory stick on the data logger screen and wait for the logger to instruct you it is safe to remove the memory stick

b. Remove memory stick from the data logger

c. Insert into a laptop and review the log.txt file for the current date – this will be located within WWW\Current Date

d. Check the file opens and contains logged events

e. Remove USB memory stick from laptop/computer and reinsert into data logger.

This applies to slave loggers only.

1.6 Check the IND light is flashing steadily showing connection to the master data logger

2. Inspection and Test

2.1 Check all data and power cables are connected securely and are fully inserted to both the data logger and the breakout board.

2.2 To check the health of the internal UPS follow UNINTERRUPTIBLE POWER SUPPLY TESTS (057)

NOTE: The test period should be for a minimum of 30 minutes and a maximum of 3 hours.

Whilst this test is being carried out on a master data logger observe the change in state of the icon on the bottom of the screen in accordance with Appendix A.

PERIODIC TASK

3. Internal Inspection and Battery Replacement

3.1 Periodic replacement of the data logger battery should only be carried out by the manufacturer or an approved agent and in accordance with the manufacturer's procedure.

It is recommended the battery should be replaced every 5 years.

This task shall only be carried out when the data logger has been disconnected from mains power and fully shutdown.

APPENDIX A

	**Relay^{ALERT} data logger icons**
	Icon when memory stick inserted
	Icon when memory stick removed
	Icon when mains power connected
	Icon when mains power removed

END

Includes:	Power Ground Frame, Mechanical Ground Frame
Excludes:	Points, Signals and Connections

SERVICE A

1. Visibility

1.1 Check signals and points are visible from the ground frame.

The operator shall have an unobstructed view of signals and points or is provided with indications.

2. Power Ground Frame

2.1 Maintain the trackside apparatus case/housing in accordance with NR/SMS/PartC/EL21 (Trackside Apparatus Case).

2.2 Maintain the switch panel in accordance with NR/SMS/PartC/SB11 (Signallers Control & Indication Panels or Displays).

3. Mechanical Lever Frame

3.1 Maintain in accordance with NR/SMS/PartC/LV11 (Lever Frames - Non Specific) or NR/SMS/PartC/LV12 (Lever Frame - Direct Locking), as relevant to the frame type.

4. Structure

4.1 Check structure, landing boards, staging, handrails, and stanchions (etc) for signs of serious rotting, corrosion, cracks, deterioration or damage. Report significant deterioration as corrective maintenance

4.2 Check that all covers and boards are properly fitted.

5. Cables and Wires

5.1 Check tail cables are correctly routed, secure and free from damage.

5.2 Check cable terminations. Protect as necessary.

5.3 Examine wires and cable cores for signs of damage and degradation.

5.4 Check that wiring is secure, properly routed and clear of moving parts.

6. Diagram

6.1 Check diagram is clean, legible, undamaged and secure.

6.2 Clean using damp cloth, dampened with dilute detergent.

7. Electric Locks and Circuit Controllers

7.1 Maintain in accordance with NR/SMS/LV21 – LV41.

8. Key Release Instrument

8.1 Maintain in accordance with NR/SMS/PartC/LV51 (Key Release and Token Instruments).

9. Plunger/Switch

9.1 Dust and examine plunger/switch mechanism, linkage, terminations, wires and fixings.

10. Needle Indicator (Spagnoletti)

10.1 Dust and examine exterior.

10.2 Check clarity of label/artwork.

10.3 Examine interior mechanism, particularly for:

a) Any damage or misalignment to needles/banners. Do not attempt to clean or oil.

b) Degraded terminations or wires.

10.4 Clean the glass.

10.5 With no current applied, gently operate the needle by hand. Observe it returns smoothly and rapidly when released.

10.6 Apply current for each position and check that the needle does not overdrive.

10.7 Check wires cannot be trapped or damaged; carefully replace and secure cover.

10.8 Request the Signaller to operate and observe correct operation.

11. Lamp Indicators

11.1 Dust and examine exterior.

NOTE: *Carefully remove the cover.*

11.2 Examine the interior, pay particular attention to:

a) Terminations and wires.

b) Lenses and lens engravings.

11.3 Check the lamps.

11.4 Clean the glass.

11.5 Examine fixings.

11.6 Carefully replace and secure cover.

11.7 Request the Signaller to operate and observe correct operation.

12. Telephone

12.1 Maintain in accordance with NR/L3/TEL/30181/011 - Maintenance of Operational Telephones.

SERVICE B

13. Function Test (Mechanical Lever Frames)

Simple ground frames only (e.g. 1 releases 2, 2 reverse locks 1). Layouts that are more complex might require a certified tester. If in doubt, ask your SM(S).

13.1 Check that the release lever is locked until a release is given by the controlling signal box or release mechanism/key.

13.2 Obtain a release and test (pull through) the operation of the ground frame.

13.3 Check that the controlling signal box cannot take the release back or the release mechanism/key remains locked until the release lever is replaced normal in the frame.

When replaced normal, check that the controlling signal box can take the release back or the release mechanism/key is unlocked and the release lever is locked.

14. Function Test (Power Ground Frames)

14.1 Check that the panel is inactive until a release is given by the controlling signal box.

14.2 Test the operation of the switch panel.

14.3 Check that the controlling signal box cannot take the release back until the panel is normalised.

When normalised, check that the controlling signal box can take the release back and the panel is inactive.

END

Mobile telephones that are switched on shall not be brought in close proximity of operational VDU based equipment.

SECTION INDEX

1. IECC – Classic
2. IECC – Scalable
3. Modular Control System (MCS)
4. WESTCAD
5. ElectroLogIXS

1. IECC - CLASSIC

Integrated Electronic Control Centre (IECC) - Classic.

Commonly Used Abbreviations.

Abbreviation	Meaning
ARS	Automatic Route Setting Subsystem
DIS	Flexible Display Subsystem
ECS	External Communications Subsystem
FBS	Fringe Box Subsystem
GWS	Gateway Subsystem
ISM	IECC System Monitor Subsystem
RII	Remote Interlocking Interface Subsystem
SDS	Signalling Display Subsystem
SPAD	Signal Passed at Danger
SSI	Solid State Interlocking
TTP	Timetable Processor Subsystem
IPL	Data Logging Facility
VDU	Video Display Unit (Monitor)

Table 1 - Commonly Used Abbreviations

ARS The ARS determines the optimum routing of trains in the area based on the timetable, their current position, their importance and their destination. It automatically requests the required route when they are available.

DIS DIS is a PC based operating interface between the IECC and the Signaller.

ECS The ECS provides an interface between the information networks and systems that cannot use the IECC's communications protocols or data notations.

FBS The FBS provides a train describer map, interpose and cancel facilities for the fringe Signaller via a monitor and keyboard.

GWS The GWS provides a link between the signalling network and the information network. It transfers information between the two when the source and destination are not on the same network. It also provides a buffer storage facility between the two networks.

ISM The ISM monitors the operation of all the subsystems in the IECC system and of the two networks and reports the system status to the Technicians. It also provides aids for fault finding and for reconfiguration of the IECC.

RII The RII enables a relay interlocking to be interfaced into an IECC in place of using a SSI interlocking.

TTP The TTP processes the timetable information for the IECC and the surrounding areas. This information is used by the ARS.

IPL The IPL provides the data logging facility in place of the PSM where the IECC is equipped with a DIS vice an SDS.

Master/Standby Changeover Testing

You shall liaise with the Signaller before initiating a changeover from master to standby. The changeover shall be initiated by command from the ISM (except when testing the status control panel).

Use the manual reset to restore from the failed to the available state and observe that further transition to standby takes place.

Following an ARS changeover, the Signaller needs to re-enable the ARS sub-areas as required.

Subsystem status shall be confirmed by using the ISM.

DIS Hot Standby

The DIS hot standby is confirmed by observing that the VDU information remains the same before and after a manual operation of the video switch.

Circuit Boards

To avoid damaging the circuit boards refer to the instructions in the IECC Technical Handbook, section IECC 6000 before attempting to extract, insert or move boards.

ISM Printout

Alarms/reports on the printout shall be noted and action taken as necessary.

ISM Printer

Printer paper and cartridges/ribbons shall be changed as detailed in the printer manufacturer's instructions.

Recording Medium, Storage and Rotation

The recording mediums should be handled carefully and removed from service if found to be damaged.

They should not be stored in hot or damp places and should be kept away from any magnetic fields.

They should be used in rotation to store data for a given period (this is usually seven days). The medium containing the oldest data should be used as the next replacement.

Tape Head Cleaning

Tape heads shall be cleaned as detailed in the manufacturer's instructions. Head cleaning tapes SHALL NOT be used.

Keyboard Maintenance

Keyboards should be held upside down when dusted.

VDU Screen Cleaning

Screens should be cleaned using an anti-static VDU cleaner following the manufacturer's instructions.

Tracker Ball

If the action of the tracker ball is not smooth, it should be cleaned or replaced.

VDU

VDU monitors using cathode ray tubes as the display media do require the degaussing if the colour display has deteriorated. In severe cases the monitor should be changed.

This does not apply to LED monitors.

Records

Record all IECC associated activities along with the time, date and signature in the site log.

IECC (Upgrade U003) System Architecture

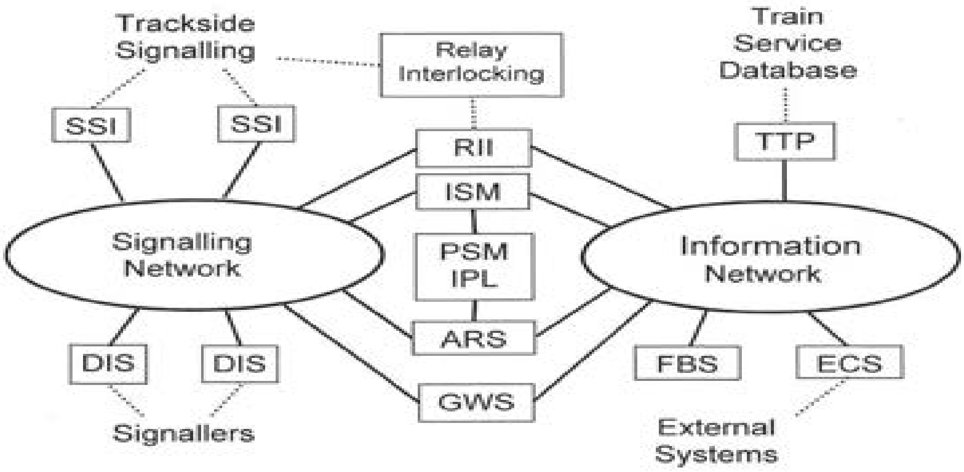

Figure 1 – IECC System Schematic

2. IECC - Scalable

Integrated Electronic Control Centre (IECC) – Scalable system description

IECC Scalable is a modern Signalling Control system designed to use up to date computer and network components commonly found in many high availability information technology applications.

The system provides the Signaller with the tools to monitor and control train movements and the state of the signalling infrastructure through a VDU based workstation.

IECC Scalable comprises sub-systems which replicate the functions of those found in IECC Classic. Ethernet network technology and a new sub-system, the Message Broker replaces the Nine-Tile network or Advanced Virtual Network of IECC classic.

Commonly Used Abbreviations

Abbreviation	Meaning
ARS	Automatic Route Setting Sub-system
CEG	Combined ECS and GWS
DIS	Flexible Display Sub-system
ECS	External Communications Sub-system
GWS	Gateway Sub-system
ISM	IECC System Monitor Sub-system
NAS	Network Attached Storage
RAID	Redundant Array of Inexpensive Devices
SII	SSI Interlocking Interface Sub-system
SSI	Solid State Interlocking
TD	Train Describer
TI	Technician's Interface
TTP	Timetable Processor Subsystem
VDU	Video Display Unit (Monitor)

Table 2 - Commonly Used Abbreviations

ARS The ARS determines the optimum routing of trains in the area based on the timetable, their current position, their importance and their destination. It automatically requests the required route when they are available.

CEG CEG provides the IECC Scalable with an interface to systems which provide data to and/or receive data from IECC Scalable, but do not use standard IECC Scalable protocols or data structures. E.g. TDs at adjacent signal boxes, SMART, etc.

DIS The DIS is a PC based operating interface between the IECC and the Signaller.

ISM The ISM monitors the operation of all the subsystems in the IECC system and of the two networks and reports the system status to the Technicians. It also provides aids for fault finding and for reconfiguration of the IECC. Interrogation of the ISM is via the TI.

SII Manages communications with SSI (and SSI derived interlockings) forwarding controls to the interlocking and receiving state of railway indications. SII also passes the interlocking diagnostic status to other Scalable sub-systems.

TTP The TTP processes the timetable information for the IECC and the surrounding areas. This information is used by the ARS.

NAS The NAS provides the data logging facility for ISM, ARS and TTP. This uses RAID technology and enables hot-swapping of the Hard Disk Drives.

Master/Standby Changeover Testing

You should liaise with the Signaller before initiating a changeover from master to standby. The changeover should be initiated by command from the ISM (except when testing the status control panel).

Use the manual reset to restore from the failed to the available state and observe that further transition to standby takes place.

Following an ARS changeover, the Signaller needs to re-enable the ARS sub-areas as required.

Subsystem status should be confirmed by using the TI.

DIS Hot Standby

DIS Hot Standby is confirmed by observing that the VDU information remains the same before and after a manual operation of the video switch.

Circuit Boards

These are susceptible to damage through electro-static discharge and through physical damage while handling. To avoid damaging the circuit boards refer to the instructions in the IECC Scalable maintenance manual before attempting to extract, insert or move boards.

Keyboard Maintenance

Keyboards should be held upside down when dusted.

VDU Screen Cleaning

Screens should be cleaned using anti-static VDU cleaner following the manufacturer’s instructions.

Tracker Ball

If the action of the tracker ball is not smooth, it should be cleaned or replaced.

Records

Record all IECC associated activities along with the time, date and signature in the site log.

3. Modular Control System (MCS)

The control system is generically called a Modular Control System (MCS). The structure of the system can vary depending upon the equipment it includes and the task it is performing.

Later systems are based around the Delphin 1024 platform or the Sapphire T48 platform; these can be configured as different sub-systems within the overall system.

The Signallers control equipment can be a VDU based control centre or a panel based control centre using a switch or NX panel.

As the system is 'modular' the SMSs for this equipment are separate. For the preventative maintenance of an MCS system some or all of the following SMSs are applicable:

SMS	Title
NR/SMS/PartC/CS06	Control System - Modular Control System
NR/SMS/PartC/IC51	Logging & Archive System (formerly GETS)
NR/SMS/PartC/IC61	Rugby Whole Route Display System
NR/SMS/PartC/TD42	GE Automatic Code Insertion (ACI) Terminal
NR/SMS/PartC/SB11	Signallers Control & Indication Panels or Displays

Table 3 - Maintenance Tasks

The tests applicable to the system (NR/SMS/PartB/Test/) are linked from the task SMS. Your work order advises you as to which tasks and tests are applicable to the system you are maintaining.

NOTE: *Earlier MCS systems not based around Delphin 1024 or Sapphire T48 platform are covered by other SMS's.*

System Architecture

The diagrams on the following pages give an outline of the system architecture for the permutations of GETS systems based on the Delphin 1024 and the Sapphire T48.

Please note that these are generic outlines and actual system configurations can vary, if you are in any doubt about the configuration of the system you are working on, ask your SM(S).

DELPHIN 1024 SYSTEM - RC / TDM & PIIU SYSTEMS

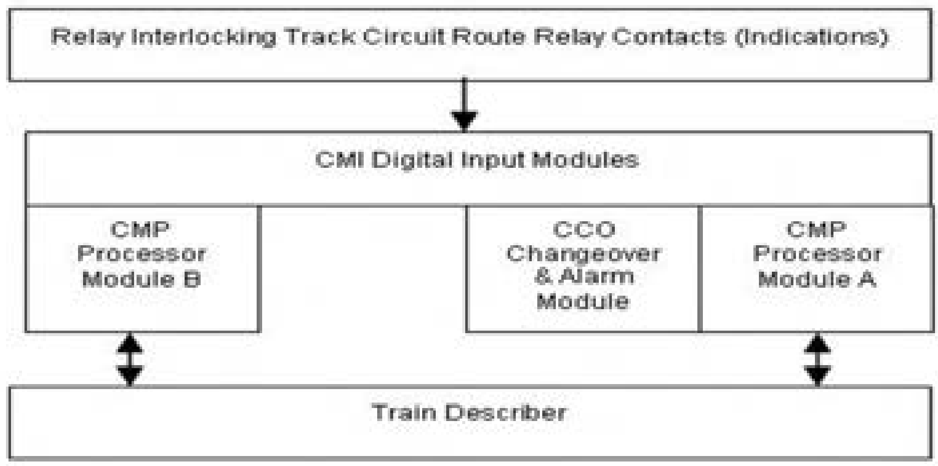

Figure 4 - Field End - TDMUX Systems

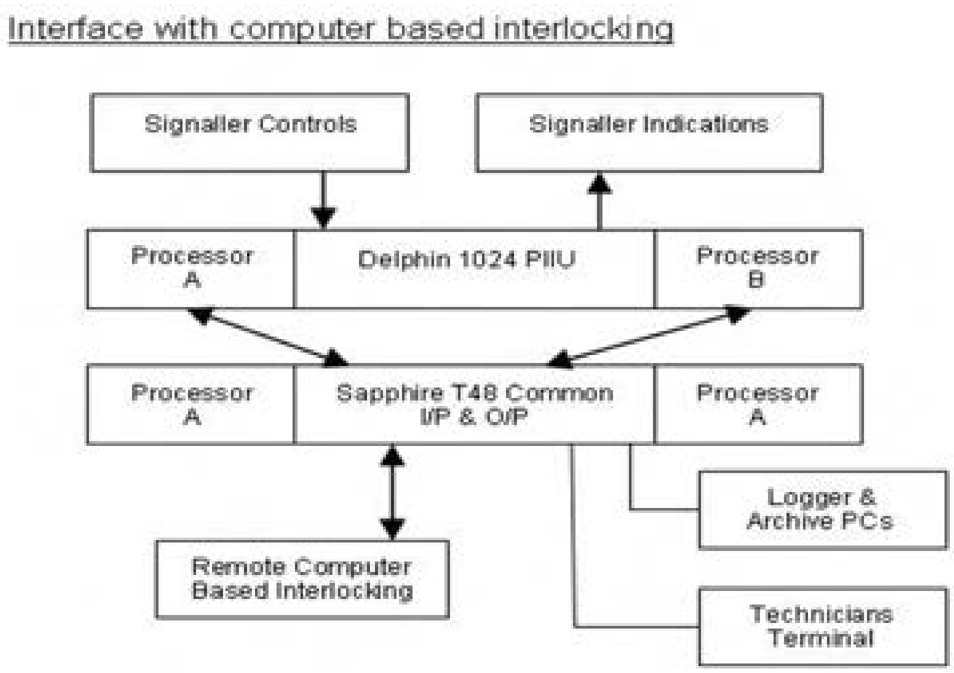

Figure 5 - Sapphire T48 Systems

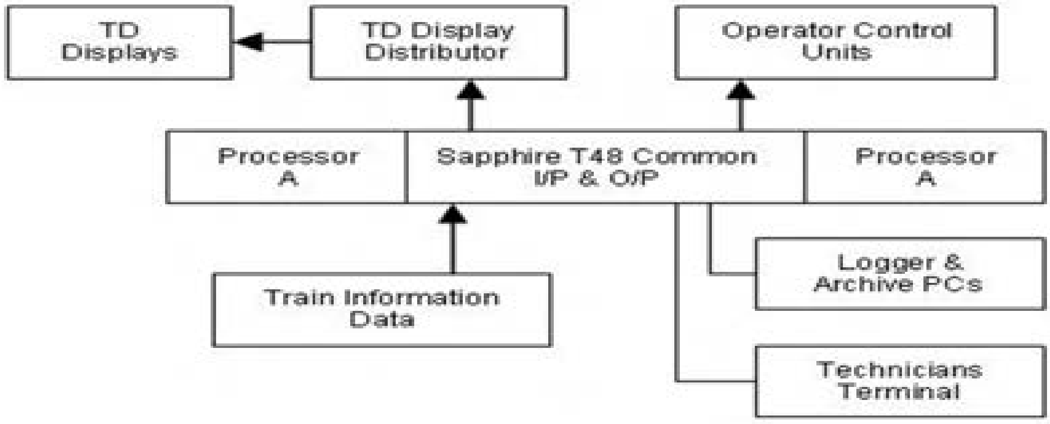

Figure 6 - Train Describer Interface

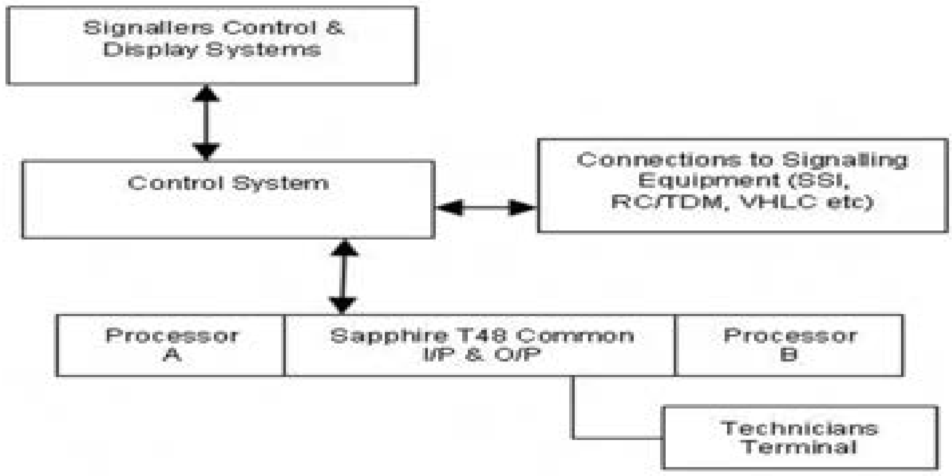

Figure 7 - SPAD Alert System

4. WESTCAD

Controlguide WESTCAD is an integrated Signalling Control System that provides a flexibly configurable platform for the control and indication of railway signalling.

This typically has a Signaller's user interface in the form of either a VDU based workstation or via a panel, and an interlocking control interface which can be to CBIs, SSIs, RRIs, or a combination of these.

WESTCAD can have an integral Train Describer (TD) or be interface to an external TD.

Automatic Routeing functions might be integrated or provided by interfacing to third party ARS products.

The WESTCAD system might be configured as a single hardware unit or as interconnected sub-systems performing specific functions.

The sub-system interconnection might be direct serial interfaces or by Ethernet networks.

There are two variants of the WESTCAD hardware platform: those based on legacy Compact-PCI modules and those using the later Modular Control Rack (MCR).

WESTCAD systems or sub-systems are assembled from standard modules comprising:

a) Power supplies and power filters.

b) CPUs and rear transition cards.

c) System Arbiter and rear transition cards.

d) Video output.

e) Serial Communications interfaces.

f) Video change-over.

g) Serial Communications change-over.

h) Modems.

Systems can have single or dual PSUs, Single or Dual CPUs. Modems can be integrated or external (depending on the Platform used).

A typical dual-redundant MCR system might have the following configuration:

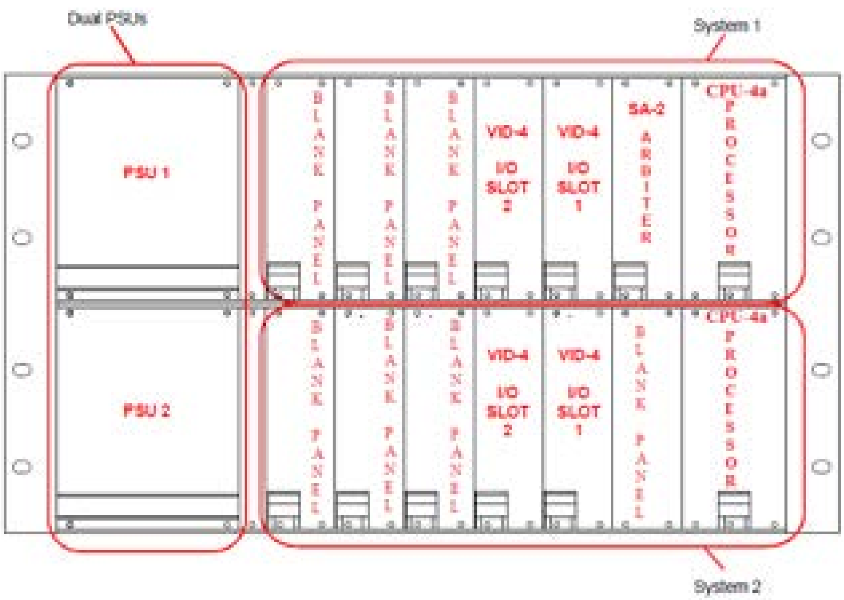

Figure 8 - Front Mounted Modules

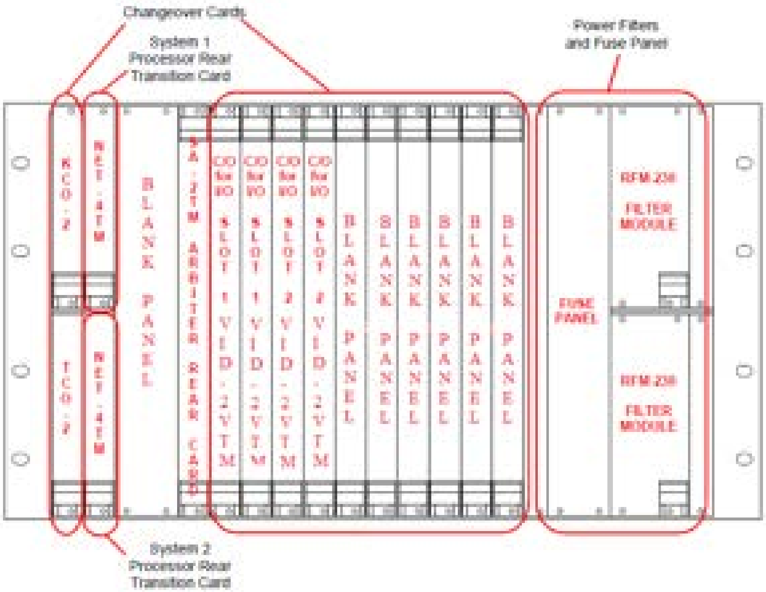

Figure 9 - Rear Mounted Modules

A PC based Technicians' terminal provides logging facilities and allows reconfiguration of the display system if necessary.

The terminal can be remote from the WESTCAD system and connect via a local area network (LAN) link.

Controlguide WESTCAD-E is a development of WESTCAD which provides additional interfaces and functionality to support the introduction of Traffic Management (TM) systems, ETCS signalling, and Automatic Train Operation.

This product uses the same MCR hardware platform as WESTCAD, but is configured into specific sub-systems:

a) Service Control Server (SCS).

b) Service Control Workstation (SCW).

c) Service Control Terminal (SCT).

d) ETCS Diagnostics Terminal (EDT)

e) Remote Interface (RIF) variants -

- Interlocking.
- RBC.
- Voice.
- CCTV.

Each system configuration only uses those sub-systems that are required for that instance, e.g. non-ETCS configurations do not need an SCT.

5. ElectroLogIXS

The ElectroLogIXS VLC is a generic logic processing platform, with the functionality being defined by the software i.e. the ElectroLogIXS System Software.

This means an ElectroLogIXS can be configured by the application designer to fulfil the functionality of different signalling system components that would normally use bespoke products.

For example, a single ElectroLogIXS unit can be used as the basis for an interlocking, or an object controller, or both simultaneously.

Some of the plug-in hardware ("modules") are the same for both configurations, and some might be different, and the application data stored in the unit is different, but the general features, limitations and appearance are the same.

All application modules have front panel indicators that display module health status and indicate individual I/O status.

Parameter set-up and modifications can be performed via the VPM-3 web graphical user interface (web GUI) or via a local control/display unit at the ElectroLogIXS.

The Web GUI runs on a separate computer, or similar device, running a web browser.

There are 3 chassis types; 1, 4 and 9 slot, which correspond to the numbers of Vital I/O and/or Lamp Driver modules that can be accommodated.

It does not require air conditioning or forced air cooling, so when used at the trackside, it is normally installed in a location case.

There are two power feeds into the ElectroLogIXS one 12V supply to the chassis, then each VLD-R8AC also has a separate 110Vac supply onto the personality module.

END

Includes:	Automatic Route Setting Subsystem; External Communications Subsystem, Flexible Display Subsystem, Fringe Box Subsystem, Gateway Subsystem, IECC System Monitor Subsystem, Remote Interlocking Interface Subsystem, Signalling Display Subsystem, Timetable Processor Subsystem IECC PC Logger, PC SPAD Monitor
Excludes:	

DAILY SERVICES

1. IECC System Monitor Subsystem

1.1 Check that the ISM terminal is functioning correctly.

1.2 Check that the ISM displayed time is identical to Rugby clock time, and the Anthorn (formally Rugby) clock readouts are identical.

2. Printer

2.1 Check the paper supply and reload as required.

2.2 Check the quality of the printout and if necessary, replace the printer cartridge/ribbon

3. All Subsystems

3.1 Observe all equipment, panel and board indications are illuminated as for normal working.

3.2 Rectify any faults that are indicated on the ISM alarm panel and the RII field indication panel.

3.3 Check Node statistics on the ISM and record results in log book.

If a significant number of rejected packets or checksum errors are shown (i.e. greater than 1% of all 3.1 packets sent) then report it to your SM(S).

4. Recording Media Replacement

4.1 Remove the recording media(s) and re-load in the correct rotation order a recording media(s) in the Timetable Processor Subsystem.

5. PC SPAD Monitor or IECC PC Logger

5.1 Check using the PSM/IPL Technician facilities that the ARS and ISM are logging data correctly.

REGULAR SERVICES

6. IECC System Monitor Subsystem

6.1 Dust the keyboard and clean the VDU screen.

7. Flexible/Signalling Display Subsystem

7.1 Check that the crosshairs cursor is steady.

7.2 Check that all text is displayed on each monitor and that the cursor is visible when positioned in each corner of the display.

7.3 Check the operation of the tracker ball.

7.4 Check the monitor(s) for picture quality. Clean the monitor(s) screen(s). Replace with site spares and send defective monitors for servicing as necessary.

7.5 Dust the keyboard. Check its condition and change if necessary.

7.6 Check that the offline unit is at hot standby.

To check for hot standby, observe the signalling screens and perform a manual changeover of the video switch.

Check that the signalling screens are the same as previously observed, then reset the video switch to its original position.

This task shall only be performed with the Signaller’s permission.

SERVICE A

8. Standby Changeover (ARS, DIS, ECS, GWS, ISM, RII, SDS TTP and IPL).

8.1 Check that the non-operational computer unit is in a standby state and if SDS/DIS that it is at hot standby.

8.2 Change over the standby to master from the ISM terminal, check the changeover is successful.

8.3 Restore the previous master from failed to standby by pressing the reset button.

8.4 Initiate subsystem change, by using the status control panel change over pushbutton (not applicable on Vaughan IECC).

8.5 Check that the changeover was successful.

Observe that the IECC works correctly and the expected message is displayed in the system alarm window on the Signaller's workstation.

8.6 (Where fitted) observe that the serial line switches change from all green to all red indications (or vice versa) on a subsystem changeover.

8.7 Restore units from failed to standby by pressing the reset button(s).

8.8 Initiate a changeover to leave the original Standby in the Master state.

8.9 Check that the offline unit is in Standby mode.

8.10 Check that all the subsystems are fully operational from the ISM terminal.

SERVICE B

9. Recording Heads

9.1 If fitted, clean the recording media heads in the Timetable Processor Subsystem in accordance with the manufacturer's instructions.

This task is not applicable if the TTP-Server PC is installed.

10. All Subsystems

10.1 Check the following items:

a) The equipment is securely mounted.

b) The cables are undamaged.

c) The cable connectors are secure.

10.2 Clean the outside of the equipment cubicle and Dust the interior units.

10.3 Isolate the 110V feed to each node crossflow fan, remove the front grill, and extract the filter and check/clean the following:

a) The fan bearing for wear.

b) Clean or replace the filter, replace the front grill and reconnect the 110V supply.

c) Each fan operates correctly.

10.4 Dismantle the tracker ball assembly; Clean the tracker ball and its associated housing. Reassemble and verify correct operation.

10.5 (As necessary) degauss the CRT monitor(s).

11. SPAD Monitoring Facility

11.1 In liaison with the Signaller set up a number of SPAD scenario's using the SSI Technician's terminal to check the Monitoring Facility is functioning correctly.

The frequency shall not exceed 1 year.

This task is not necessary if SPAD has occurred on the workstation since the last maintenance visit.

PERIODIC TASKS

The tasks in sections 12 to 13 are not all at the same periodic frequency.

Unless the frequency is specifically stated below then ask your SM(S) for details of the manufacturers recommended frequencies, which are detailed in relevant sections of The IECC Technicians Manual NR/GN/SIG/19053.

Technical support staff and/or equipment specialists can manage these tasks separately. These tasks should be carried out in an electronic workshop environment.

12. Battery Replacement All Nodes

12.1 Replace the battery at 2 yearly intervals.

MVME 162, 172 and 215 Processor Boards.

12.2 Replace the board-mounted batteries in accordance with the IECC Technicians Manual NR/GN/SIG/19053 Section 5N.

<u>All IECC PCs</u>

12.3 Replace the internal batteries in accordance with the IECC Technicians Manual NR/GN/SIG/19053 Section 5N.

13. Fan Replacement

<u>All IECC PCs</u> (except TTP-Server PCs)

13.1 Replace the following equipment cooling fans on each PC with new units of the same type at 3 yearly intervals.

a) PC front air intake (x2).

b) Internal PC processor fan.

c) PC power supply.

Check after replacement that each fan works correctly.

END

Includes:	All IECC Scalable Sub-systems and components (including Scalable 2)
Excludes:	IECC Classic equipment

Record the results of all actions in the system logbook/Technicians Logsheet.

DAILY SERVICES

1. IECC Scalable Technician's Interface

1.1 Check that the Technicians Interface (s) are functioning correctly and that all subsystems / equipment it reported upon are healthy (see IECC Scalable & Middleware Technicians Interface User Manual).

1.2 Rectify any faults that are indicated by the Technicians Interface.

WEEKLY SERVICES

2. Data logging Health check

2.1 Check that the ARS and Status Monitor data is logging correctly using the IPL remote client or the IPL local Technicians interface.

2.2 Rectify any faults that are discovered.

3. IECC System Cabinets

3.1 Observe all equipment, panel and board indications are illuminated as expected, for normal working or carry out a "Remote System Status Check".

3.2 Rectify any faults that are indicated.

3.3 Observe the time on each TTP unit relative to the Network Clock. If the drift is greater than 1 minute, manually set the TTP time to match the Network Clock using the TCF client.

4. DIS System Cabinets

4.1 Observe all equipment, panel and board indications are illuminated as expected, for normal working both front and back panels or carry out a "Remote System Status Check".

4.2 Check the workstation Remote Level Convertor front and back panels for normal indications.

5. Middleware Cabinets

5.1 Observe all equipment, panel and board indications are illuminated as expected, for normal working or carry out a “Remote System Status Check.

5.2 Observe the Management PC and the Middleware Technician’s Interface are operating correctly.

MONTHLY SERVICE

6. Operator Interfaces

6.1 Check that the cursor or mouse pointer is steady.

6.2 Check that all text is displayed on each monitor and that the cursor or mouse pointer is visible when positioned in each corner of the display.

6.3 Check the monitor(s) for picture quality. Replace defective monitors with site spares and investigate the cause. Send defective monitors for servicing as necessary.

6.4 Clean and dust all monitors.

6.5 Dust the keyboard. Check its condition and change if necessary.

6.6 Check that the offline unit is at hot standby. To check for hot standby, observe the signalling screens and perform a manual changeover of the video switch. Check that the signalling screens are the same as previously observed, and then reset the video switch to its original position.

This task is applicable for DIS only and shall only be performed with the Signaller’s permission.

6.7 Dust and clean the Technician Interface keyboard and screen.

SERVICE A

7. Middleware and Upgraded Workstation

7.1 Check there is backup mouse and keyboard stored in a location convenient for the Signaller and replace if missing.

8. Standby Change-Over

This task shall only be performed where the DIS & blades operate in master/standby configuration.

Come to a clear understanding with Signaller, the implications of each subsystem changeover.

8.1 Check that the non-operational unit is in a standby state. For the DIS, check that it is at hot standby (see Technicians Interface User Manual).

8.2 Reboot the standby units and check they return to a standby state correctly.

8.3 Initiate subsystem change-over by using the Status Control Panel change-over pushbutton.

8.4 Check that the change-over was successful.

8.5 Observe that the IECC Scalable works correctly and the expected message is displayed in the system alarm window on the Signaller's workstation.

8.6 Restore units from failed to standby by pressing the reset buttons.

8.7 Check that all the subsystems are fully operational from the Technician's Interface terminal.

9. IECC Scalable Chassis Fan Filters

9.1 Replace the chassis Fan Filters (See IECC Scalable Hardware Maintenance & Fault Finding Manual).

9.2 Check the Technician's Interface to ascertain that it reports good health status for the Chassis, CMM, Fan Tray and Power Supply.

10. DIS Host , DIS PC and TI Fan Filters

10.1 Replace DIS Host, DIS PC and TI Fan Filters (See IECC Scalable Hardware Maintenance & Fault Finding Manual).

10.2 Check that DIS Host, DIS PC and TI are operating correctly.

11. Middleware Fan Filters

11.1 Replace Management PC and the Middleware Technician's Interface PC Fan Filters (see Middleware Maintenance & Fault Finding Manual).

SERVICE B

12. All IECC Scalable, DIS,TI Middleware cabinets and workstations.

12.1 Check the equipment is securely mounted.

12.2 Check the cables are undamaged.

12.3 Check the cable connectors are secure.

12.4 Dust and clean cabinets and workstations.

13. SPAD Alarm Test

13.1 In liaison with the Signaller set up a number of SPAD scenario's using the SSI Technician's terminal to check the Monitoring Facility is functioning correctly.

The frequency shall not exceed 1 year.

This task is not necessary if SPAD has occurred on the workstation since the last maintenance visit.

13.2 For SSI (also WESTLOCK or Smartlock) set up a SPAD scenario using the interlocking Technician's terminal for a sample of routes not less the three for each workstation.

13.3 For relay interlocking, perform a SPAD Alarm test as described in the IECC Scalable Technicians Interface User Manual.

13.4 Repeat 13.1 and 13.2 for each IECC Scalable Signaller's Workstation.

PERIODIC TASKS

14. All Blades, PCs and Radio Clocks

14.1 As per Table 1-Periodic tasks, replace the batteries in the listed components at the specific frequency.

Intervals	Description	Cycle
Periodic task 1	Blade Batteries	2 years
Periodic task 1	DC PC Battery	2 years
Periodic task 1	DIS Host PC Battery	2 years
Periodic task 1	TI Battery	2 years
Periodic task 1	Management PC Battery	2 years
Periodic task 1	MTI PC Battery	2 years
Periodic task 2	Workstation PC	4 years
Periodic task 2	NAS RAID	4 years
Periodic task 3	MSF Network Clock	9 years

Table 1 – Periodic Tasks

END

Includes:	Compact-PCI hardware-based versions of WESTCAD and Interface Systems (see appropriate NR/SMS for system type)
Excludes:	Siemens Controlguide WESTCAD and WESTCAD-E – MCR hardware-based versions (see NR/SMS/IC16)

GENERAL

Cable routes shall not be altered from their original position (if in doubt refer to the drawings manual). Never re-route cables during maintenance.

A usable copy of the Westcad maintenance manual should be available on site, if missing or damaged inform your SM(S).

The site software should be available although this might not be on site but held by the technical support group.

DAILY SERVICES

1. Technicians' Terminal

1.1 Check that the terminal remote access facility is working.

1.2 Any outstanding fault messages shall be investigated and cleared as corrective maintenance.

REGULAR SERVICES

2. Control Equipment Cubicle

2.1 Check that the LEDs on the CM2 module are showing as in Table 1.
If any LED is not showing as indicated, refer to the system maintenance manual.

LED	State
Sys 1 On Line	Illuminated if On Line, Extinguished if Off Line
Sys 2 On Line	
Sys 1 Available	Illuminated if Off Line, Extinguished if On Line
Sys 2 Available	
Sys 1 Watchdog	Flashing if Off Line, Extinguished if On Line
Sys 2 Watchdog	
Auto Latch	Flashing
PSU Fail	Extinguished

Table 1 – System LEDs

If any LED is not showing as indicated, refer to the system maintenance manual.

2.2 Check that the cubicle earth terminal is securely bonded to the equipment room earth point.

2.3 Visually check all cables and connectors are secure.

2.4 Check that the area in and around the cubicle is clean and tidy. Remove any rubbish and debris.

2.5 Check that all the cubicle doors are closed. The cubicle provides EMC protection, any signs of damage or deterioration shall be reported as corrective maintenance.

3. Surge Protection Units

3.1 Where Fitted: Carry out NR/SMS/PartB/Test/062 (Line Protection Unit Test).

SERVICE A

4. System Changeover

4.1 Check that the LED indications on the CM2 or system arbiter module are showing as per 2.1.

4.2 Set the rotary switch to manually select the off-line system and observe that the systems switch over.

4.3 Check the Technicians terminal fault reports to ascertain the system is working correctly.

4.4 Set the rotary switch back to the ‘Auto’ position.

4.5 Check that the ‘Auto Latch’ LED is flashing, if not press the ‘Latch Reset’ button.

4.6 Check that the Signaller’s workstation(s) are operating correctly.

5. Equipment Cleaning

5.1 Clean all monitor screens and housings with a proprietary anti-static dry screen cleaner. Use cleaning products in accordance with the manufacturer’s instructions.

5.2 Disconnect and clean the keyboard as necessary. Hold the keyboard upside down while cleaning.

5.3 Disconnect and clean the tracker ball / mouse. If necessary (if the operation has become intermittent or jerky), remove and clean the ball and rollers.

5.4 Check fans are working, and filters are clean. See appendix B.

6. Technicians' Terminal

6.1 Check that the time on the Technicians' terminal (bottom right of the monitor screen) is correct, re-set if necessary (Appendix A).

The internal clock on the Technicians' terminal is not controlled by the Anthorn (formally Rugby) clock therefore some drifting might occur. The change from GMT to BST and vice versa necessitates re-setting the time.

SERVICE B

7. System Reboot

This is only required on Systems running on the Windows NT operating system.

7.1 The two off line systems should be rebooted one at a time.

Remember to allow time for each system to collect all of the "state of the railway" information it requires. While this collection of information is taking place, the system appears to be in a failed state, hence the need to wait.

7.2 When both off line systems are operating normally the on-line system should be changed over to one of the now rebooted systems.

7.3 The system which was on line shall now be rebooted.

If this task is not completed for any reason the SM(S) shall be advised.

8. Cubicle Cleaning

8.1 With the front and rear doors closed, clean the outer surfaces using a dry lint free cloth.

8.2 Carefully dust the interior faceplates and blanking panels with a dry lint free cloth.

8.3 Check that all doors are securely closed on completion of cleaning. The cubicle provides EMC protection, any signs of damage or deterioration shall be reported as corrective maintenance.

PERIODIC TASKS

9. Computers

The routine replacement of the PC hard disk drive is only required on early versions of the system.

9.1 Replace the PC hard disk drive (HD) with a new HD of the same type.

APPENDIX A

Adjustment of Clock on Technicians' Terminal

1. On the windows task bar at the bottom right of the screen, double click on the time display with the left-hand mouse button. A date/time properties dialogue box is displayed.

2. Select 'Time Zone' by left clicking the tab. Check that the time zone shows '(GMT) Greenwich Mean Time: Dublin, Edinburgh, London, Lisbon', or select this zone from the selection in the drop-down menu.

3. Check that the tick box next to the dialog box 'Automatically adjust clock for daylight saving changes' is not ticked. If it is, un-tick it by a left hand click in the box.

4. Select 'Date & Time' by left clicking the tab. Check that the date is correct. If not select the correct month and year form the selection in the drop down menu and the date by left clicking the correct one displayed on the calendar.

5. Set up the time display for a short time in advance of the actual time. This is done by highlighting the hours figures located in the box under the clock by dragging the cursor across the figures whilst holding down the left hand button on the mouse. Adjust the hours by clicking the up or down arrows to the right of the box. Repeat for the minutes and seconds.

6. At the precise time left click the 'Apply' button and then left click 'OK'. The adjusted time is displayed in the windows task bar at the bottom right of the screen.

END

Includes:	Siemens VICOS VDU Control System
Excludes:	All other Siemens VDU Control Systems

DAILY SERVICES

1. VICOS

1.1 Check the alarm list on all VICOS terminals for any outstanding faults. Rectify or report.

1.2 Check the archive PC is recording, there are no fault messages displayed, and that the display is pink. Rectify or report.

1.3 Archive daily logs to an external recording media.

This can range from a floppy disc to a memory stick depending on the system hardware. Data is automatically over written after 7 days if not archived.

1.4 Check that the IBS_PC and IBS_PC Mirror are operational there are no fault messages displayed and that the display is updating.

Check that all the nodes in the NUC view connections window are green. Rectify or report.

SERVICE A

2. VICOS Terminals.

2.1 Clean & dust the terminal screens, keyboards, & mouse. Use a dry lint free cloth for dusting and an approved cleaning product to remove marks & stains.

Keyboards should be held upside down when cleaning.

2.2 Check that all PC GPS & Anthorn (formally Rugby) clocks are correct. Rectify or report.

2.3 Check the filters in the back panel projection units. Replace if required.

SERVICE B

3. VICOS Terminal.

These tasks shall be undertaken in liaison with the Signaller

3.1 Shutdown and then reboot the main VICOS terminal.

3.2 Login to terminal then run the static test, dynamic test & all image tests. Rectify or report any problems. On completion, log off the terminal.

3.3 Check that all the connections to the terminals are correctly seated and fixing screws are tight where applicable.

Do not inadvertently disturb anything whilst undertaking this task.

END

Includes:	Siemens Controlguide WESTCAD and WESTCAD-E – MCR hardware-based versions
Excludes:	Compact-PCI hardware-based versions of WESTCAD and Interface Systems (see relative NR/SMS for system type)

GENERAL

Cable routes shall not be altered from their original position (if in doubt refer to the drawings manual). Never re-route cables during maintenance.

Observe ESD precautions before handling any electronic equipment.

A usable copy of the WESTCAD maintenance manual should be available on site, if missing or damaged inform your SM(S).

The site software should be available although this might not be on site but held by the technical support group.

DAILY SERVICE

1. Technician's Terminal

1.1 Check that the terminal remote access facility, where provided, is working.

1.2 Any outstanding fault messages shall be investigated and cleared as corrective maintenance.

2. ETCS Diagnostics Terminal

2.1 Check clock indication is displaying white text, investigate and rectify as corrective maintenance if displaying anything else.

2.2 Any outstanding fault messages (M_ERRORs) shall be investigated and cleared as corrective maintenance.

REGULAR SERVICE

3. Control Equipment Cubicle

3.1 Check that the indication LEDs on the SA-2 module, where fitted, are showing as in Table 1.

Any fault indication shall be investigated and cleared as corrective maintenance. Refer to the system maintenance manual as necessary.

Indication	Colour	State
Power	Green	When lit indicates the 12V dc power supply to the SA-2 module is present
WD	Yellow	Watchdog - flashes to indicate the associated system is operating correctly
OL	Green	When lit, indicates which System is on-line
FT	Red	When lit, indicates conditions for indicated System Watchdog are Not true
PSU 1/ PSU 2	Green	Indicates PSU functioning normally
	Red	Indicates PSU fault

Table 1 - LED indications

3.2 Visually check that the cubicle earth terminal is securely bonded to the equipment room earth point.

3.3 Visually check all cables and connectors are secure.

3.4 Check that the area in and around the cubicle is clean and tidy. Remove any rubbish and debris.

3.5 Check that all cubicle doors are closed.

4. Surge Protection Units

4.1 Where fitted, carry out NR/SMS/PartB/Test/062 (Line Protection Unit Test).

SERVICE A

5. Equipment Cleaning

5.1 Operator's monitor surfaces shall be cleaned using a lint-free non-abrasive cloth. Do not use any cleaning solution or glass cleaner.

5.2 Keyboards shall be cleaned using a soft cloth and mild detergent solution.

Moisture shall not be allowed to enter equipment apertures and shall be dried off surfaces as soon as possible. Do not use abrasive cleaners or pads.

5.3 The Operator's mouse (where provided) shall be cleaned using a soft cloth and mild detergent solution.

Moisture shall not be allowed to enter equipment apertures and shall be dried off surfaces as soon as possible. Do not use abrasive cleaners or pads.

5.4 Disconnect and clean the tracker-ball (where provided). If the operation has become intermittent or jerky, remove and clean the ball and rollers.

6. Operators mouse

6.1 Check for correct operation of mouse left and right buttons and cursor movement response. Replace any defective mice as corrective maintenance.

7. Technician's Terminal Clock

7.1 Check that the time on the WESTCAD Technician's Terminal (bottom right of the VDU) is correct. Adjust if necessary (Appendix A).

The internal clock is free running and is not controlled by the WESTCAD time reference, some drifting might occur.

8. Fan Tray (if fitted)

NOTE: *before carrying out this task liaise with the Signaller, as an alarm is generated.*

8.1 Disconnect and slide out the fan tray, clean using a soft cloth moistened with a detergent solution.

SERVICE B

9. System Changeover (dual processor systems only)

It is recommended that this task is carried out during periods of no train movements or only light traffic.

9.1 Check that the Indications on the SA-2 module are showing as follows:

- One On-Line LED is illuminated to indicate which system is on line.
- Both 'Watchdog' LEDs are flashing.
- Power LED is illuminated.
- FT LEDs are not illuminated.
- PSU LEDs are both illuminated green.

9.2 Set the rotary switch to manually select the off-line system and observe that the systems change-over.

9.3 Check the LED indications to verify the system is working correctly.

9.4 Check the Technician's terminal fault reports to ascertain the system is working correctly.

9.5 Verify correct operation of the system at the Signaller's workstation.

9.6 Set the rotary switch back to the 'Auto' position.

10. Cubicle Cleaning

10.1 With the front and rear doors closed, clean the outer surfaces using a dry lint-free cloth.

10.2 Carefully dust the interior faceplates and blanking panels with a dry lint-free cloth.

10.3 Check that all doors are securely closed on completion of cleaning.

11. Plugs and sockets

11.1 Check that all plugs and sockets are correctly fitted and that screw fasteners are tight.

11.2 Check that all wiring connections are correctly made.

12. CPU-3 and CPU-4a Modules Checks

Lithium Batteries

12.1 Check the date on the label fitted to the front of the module which details the date the module was installed or issued as a spare.

NOTE: *These Lithium batteries have a 5-year service life.*

If four years has elapsed since the date shown on the module you shall advise your SM(S), so that arrangements can be made to replace this module and replace its battery.

Hard Disk Drives (if fitted)

NOTE: *Earlier CPU-3 Modules were fitted with Hard Disk Drives (HDD). In the case of these modules, a label is fitted to the module detailing the date this module was installed. These Hard Disk Drives have a 5-year service life.*

12.2 Check the date on the label fitted to the front of the module which details the date the module was installed or issued as a spare.

If four years has elapsed since the date shown on the module you shall advise your SM(S), so that arrangements can be made to replace this module.

13. WESTCAD MCR 12V dc PSUs

13.1 Using a Digital Multi-Meter check the output voltage of each PSU. Adjust the trim control on the PSU front panel as necessary to achieve 12.0V DC.

Appendix A - Adjustment of Technician's Terminal Clock

This instruction should be carried out as soon as possible after changes between BST and GMT to realign the WESTCAD Technician's Terminal internal clock with the WESTCAD clock.

1. If not already powered up, switch on the Technician's Terminal. At the Windows task bar at the bottom of the screen double-click on the time display with the left-hand mouse button. A 'Date/Time Properties' dialogue box is displayed.

2. Select the 'Time Zone' by clicking on the tab. Time zone should show '(GMT) Greenwich Mean Time: Dublin, Edinburgh, London, Lisbon' immediately below the tab.

   If a different legend is shown, click on the down arrow to the right of the legend and select the required GMT from the drop-down menu displayed.

3. Near the bottom of the dialogue box, check the box adjacent to the legend 'Automatically adjust clock for daylight saving changes' is NOT ticked. If it is, click in the box to remove the tick.

4. Select 'Date & Time' by clicking on the tab.

5. To change month or year, click on the down arrow next to the month/year display, then click on the required month/year on the drop-down menu displayed.

6. To set the date, position the cursor over the required date and click the left-hand mouse button.

7. Set up the time display for a short time in advance of the actual time as displayed on the front panel of the radio clock/NTP server unit or other reliable time display.

8. To set Time, scroll the cursor over the 'hours' figure located under the clock face. The figure becomes highlighted. Now click on the up or down arrow to the right of the time digits to set as required.

9. Repeat Step 8 for 'minutes' and 'seconds'.

10. At the precise time, click on 'Apply'.

11. Click on 'OK' to clear the dialogue box from the screen.

12. On completion, the new time is shown at the bottom right of the monitor screen.

END

Includes:	Signallers Assistant (TREsa)
Excludes:	Any other Signallers Assistance Equipment

TREsa is an automatic route setting system designed to help signallers by reducing working by routing timetabled services automatically.

The TREsa consists of a number of subsystems:

- A Diagnostics subsystem. This subsystem acts as a central communications hub, maintains log files and is the TREsa configuration management system.
- A Timetable server (TREtts). This subsystem receives and processes timetables from Network Rail's integrated timetable planning system (ITPS). This subsystem distributes the timetables to the rest of the system.
- A number of SARS processors. Each pair of SARS processors (one acting as Master and the other as Standby) interfaces to the control equipment and issues panel requests to set routes for trains.
- A number of SACS PCs. These subsystems provide the signaller's interface to TREsa. They provide a means of controlling ARS functions and provide the signaller with information regarding the route setting status of each train.
- A number of smaller subsystems such as a change-over system (for each SARS pair), an internet router, network switches and printers.

The SARS can run standalone, but when connected to the Diagnostics system requires a user to set them both to standby. The change-over system should then select one as the Master SARS to provide the automatic routing functions, while the other SARS operates as the standby processor.

Please refer to the System Maintenance Manual for comprehensive maintenance and fault finding instructions.

DAILY SERVICE

1. Daily Tasks

1.1 Check the Diagnostics System Status display for subsystem status.

1.2 Check the Diagnostics alarm list for alarms raised in the last 24 hours:

- If there is an alarm regarding a failed timetable download, inform the Signalling Manager.
- Contact ITPS and request a new full timetable download.

WEEKLY SERVICE

2. TREtts

2.1 Login to the TREtts PC. Open Windows Explorer and navigate to C:\TRETTS\data\backup. Remove all but the last week's database backup files; these files will have a .gbk file extension.

2.2 Remove any error files in C:\TRETTS\import.

2.3 Navigate to C:\TRETTS\data and check the size of the TRETTS.GDB file. Using the TREsa TREtts database form, note the file size against the date and check that it is less than 5GB.

If the file is now larger than 5GB, perform the backup and restore procedure (see TREtts database maintenance below).

2.4 Empty the Recycle Bin.

2.5 Using Windows Explorer, navigate to My Computer, right click on the C:\ drive icon and select Properties. Check the disk space on the C: drive. It should be no more than 80% full. If the preceding activities have not freed up sufficient disk space, contact the design authority.

2.6 Logout of the TREtts PC.

MONTHLY SERVICE

3. SARS

3.1 Inform the signallers that this maintenance task can cause all sub areas to drop out of ARS control.

The sub areas for each workstation need to be manually put back into ARS control by the signaller when the new Master SARS processor is online.

3.2 Force a change-over of SARS processors using the change-over subsystem.

This can force the current Master SARS to reboot and the current Standby SARS to be promoted to Master.

On completion of the reboot, promote the SARS to Standby using the 'SARS Control' function on the Diagnostics subsystem.

4. TRETTS

4.1 Check that:

- The TREtts is not performing a timetable import (this normally happens between 7pm and midnight every day);
- No users have a TREtts Client running.

4.2 Reboot the TREtts Server PC.

4.3 Allow up to 10 minutes for the PC to reboot and initialise, then check that the subsystem is displayed as 'up' on the Diagnostics System Status display.

SERVICE A

5. Diagnostics

5.1 Inform the signallers that they can still be able to control the ARS functions (with the exception of Parameter Set activation/deactivation) via the workstation while the Diagnostics is being rebooted.

5.2 Reboot the Diagnostics PC.

6. SACS

6.1 Inform the signallers that they can still be able to control the ARS functions (with the exception of Parameter Set activation/deactivation) via the workstation while the SACS PC is being rebooted.

6.2 Reboot each of the SACS PCs.

SERVICE B

7. General

7.1 Remove, clean and replace the air filter at the front of the all PC's.

8. Diagnostics

8.1 Remove and exchange the removable hard drive for a new one. Archive the old removable hard drive.

9. TREtts database maintenance

9.1 On the TREtts Server, stop TREtts service:

- From the Windows start menu select
  Control Panel > Administrative Tools > Services > TTPService

- Highlight TTPService, right-click and select Stop.

9.2 Using Windows Explorer, navigate to the folder C:\TRETTS\data

9.3 Rename the database file TRETTS.GDB with the current date as the prefix in the format YYYYMMDD, for example: 20150402TRETTS.GDB

Note that this filename must be used where ever DATABASE.GDB is mentioned in the instructions below:

9.4 Start a command line session:

- From the Windows start menu select Run.
- Type cmd in the dialog box then press OK.

9.5 In the command line, enter the following commands:

Note: Only if the command is unsuccessful, an error can be returned by the program, otherwise the command is deemed to be a success.

a. cd C:\Program Files\Firebird\Firebird_2_5\bin Now <press enter>

b. gbak –b –G C:\tretts\data\DATABASE.GDB C:\tretts_backup.gbk –user sysdba –pass masterkey Now <press enter>

Command on a single line:

c. gbak –b –G C:\tretts\data\DATABASE.GDB C:\tretts_backup.gbk –user sysdba –pass masterkey Now <press enter>

d. gbak –r C:\tretts_backup.gbk C:\tretts\data\TRETTS.GDB –user sysdba –pass masterkey Now <press enter>

Command on a single line:

e. gbak –r C:\tretts_backup.gbk C:\tretts\data\TRETTS.GDB –user sysdba –pass masterkey Now <press enter>

Should command b. be returned as unsuccessful, re-enter the command before attempting command c.

Should it be unsuccessful a second time, then undo the process of file renaming as described at the start of this task by renaming the file back to its original name of TRETTS.GDB. Reschedule this maintenance for one week later.

9.6 Reboot the TREtts PC.

Allow up to 10 minutes for the PC to reboot and initialise, then check that the TREtts subsystem is displayed as ‘up’ on the Diagnostics System Status display.

End

Includes:	ElectroLogIXS Electronic Interlocking / Controller 1 Slot, 4 Slot & 9 Slot Chassis'
Excludes:	All other types of Electronic Interlocking and Chassis variants

No possession arrangements are required to perform the services described below; all the tasks are non-intrusive.

Equipment Identification

1 Slot Chassis

4 Slot Chassis

9 Slot Chassis

SERVICE B

1. Cleaning

1.1 Clean the outside of the chassis using a dry lint-free anti-static cloth.

2. Visual Checks

2.1 Check for foreign material inside the chassis. Remove if electrical isolation of equipment is not required to do so, or report these findings as corrective maintenance.

2.2 Check the chassis is securely mounted.

2.3 Check that all modules are fully seated within the chassis and the locking mechanisms are in the locked position.

2.4 Check for any visual damage. Report any damage so that a replacement can be arranged as necessary.

2.5 Visually confirm that all VPM-3 and CIO-PCA module network cables are latched in position.

2.6 Examine the equipment, terminals, cables and cable connectors. Particularly look for physical damage, overheating and arcing. Rectify as necessary.

END

Includes:	Siemens WESTCAD-LC-TSD (Level Crossing Touch Screen Device)
Excludes:	WESTRONIC 1024 TDM System or WESTRONIC Eight Bit TDM

Cable routes shall not be altered from their original position (if in doubt refer to the drawings manual). Never re-route cables during maintenance.

Observe ESSD precautions before handling any electronic equipment.

A usable copy of the WESTCAD-LC-TSD maintenance manual should be available on site, if missing or damaged inform your SM(S).

The product data is stored on a CompactFlash card. The spare CompactFlash card should be available; this may not be on site but held by the technical support group.

Equipment Identification

There are two versions of the LC-TSD as follows:

- 12.1" LCD monitor with integral processor card, Siemens Part No. 615300129
- 12.1" LCD monitor with external processor installed in a 3U housing located in the workstation desk section, Siemens Part No. CAT00000000306

Cleaning Products

When cleaning the LC-TSD never use:

- Abrasive pads or paper towels.
- Window cleaner, soap or scouring powder.
- Solvents such as alcohol, benzene, ammonia or paint thinner.
- Cleaning fluids, wax, or chemicals.

Service A

1 General Cleaning

LCD screens are fragile and can be damaged if you press too hard during cleaning.

1.1 With the signaller's agreement, activate the products cleaning mode.

1.2 Clean the frame and screen with a microfiber cleaning cloth.

If that does not work, spray water directly onto the microfiber cleaning cloth.

Never spray anything directly onto the LC-TSD screen.

1.3 Return the LC-TSD to its operational mode after cleaning.

Service B

2 Regular Maintenance

2.1 Check the LC-TSD panel brightness and contrast are suitable for the user, adjust the settings as necessary.

The contrast and brightness controls are accessible after removal of a rear mounted protective cover (refer to the technical manual for additional information if required).

2.2 Visually check all cables and connectors are secure.

2.3 The field end Time Division Multiplexer (TDM) System status is displayed on the LC-TSD screen (Top middle section). Investigate further any TDM faults displayed (refer to the technical manual for additional information if required).

2.4 Check on the technician’s terminal for any LC-TSD related faults. Investigate further any LC-TSD faults displayed (refer to the technical manual for additional information if required).

End

Includes:	Logger and archive/analysis PCs
Excludes:	All other types of Logger or Archiving PC

Before working on the system ESD precautions shall be taken.

General

The Logger (or Archive Recorder) PC can be connected to a number of different systems (e.g. RC/TDMs and/or PIIUs). The logger records the information sent from these systems.

It operates in conjunction with an Archive/Analysis PC, which regularly extracts each day's information to be preserved as required on CD ROM, and which provides an analysis facility. These archived logs can then be analysed by creating reports, which can be printed.

An Archive & Analysis PC is designed to connect to the GE Logger either directly through a LAN or remotely through a modem. The messages to the Archive/Analysis hard disk are overwritten every eighth day.

The Logger transfers data to the Archive/Analysis PC every 24 hours or on request, where it is stored on a removable CDR, which is typically capable of holding one month's data.

It is recommended that six re-writeable disks are provided, labelled, and used in rotation, providing six months of stored data.

Records

All activities carried out on the Logger and Archive/Analysis PCs shall be recorded in the system log book.

REGULAR SERVICES

1. System Health

1.1 Request and print a train report for a late train from the previous day specifying date, time, and train description. This proves that the archive PC has received the previous day's data.

1.2 Check all power supply indications are correct.

2. Archive Data

2.1 Change the CDR disc in archive & analysis PC, and label and store the old disk.

2.2 Place a new CDR in the archive & analysis PC.

2.3 Check that the removed disc has accessible and readable data before storage.

SERVICE A

3. System Checks

Due to individual system configurations not all the tasks are performed on both the logger & archiving system, if you are unsure of the correct tasks, ask your SM(S).

3.1 Check that the power supply cooling fans and other cooling fans are running and that the air intakes are not obstructed on both the Logger and archive & analysis PCs.

3.2 Check that the link between the logger terminal and the train describer is reported as OK. Rectify any defect.

3.3 Check that the link (LAN or Modem) between the logger and archive & analysis PCs is reported as OK. Rectify any defect.

3.4 Check the time and date on the logger and archive & analysis PCs. If it is incorrect check the Radio Clock unit and connections.

3.5 Check the power supply indications are indicating correctly for all units.

3.6 Check that the PCs keyboards and mouse are functioning and that the display screens are working correctly. Confirm that there is a working spare keyboard and mouse on site.

SERVICE B

4. System Maintenance

4.1 Change out the Logger and Archive/Analysis PCs with the spare units. Check that the detail of each unit location and serial number is recorded in the site log-book.

4.2 Clean the display screens and housings using a proprietary anti-static screen cleaner, used in accordance with the manufacturer’s instructions. Disconnect and Clean the keyboard and mouse as required, then reconnect. Hold the keyboard upside down when cleaning.

PERIODIC TASKS

5. Equipment Servicing

5.1 Arrange for the PCs to be returned to the supplier for service and replacement of PSU and processor fans, batteries, and hard drives.

END

NR/L3/SIG/10663 Signal Maintenance Specifications		
NR/SMS/Part C/IC52		
GE Standalone FTN unit		
Issue No. 01	Issue Date: 04/03/17	Compliance Date: 31/05/17

Includes:	Standalone FTN unit
Exclude:	

ESD Precautions.

Before working on system use appropriate ESD precautions.

General

FTN Protocol Converter Unit interfaces the TDM products via the Network Rail Fixed Telecom Network fibre infrastructure. This product adds a wrapper layer to the serial (PS9) message structure of the TDM system.

Records.

All activities carried out on the unit shouldbe recorded in line with current maintenance standards.

A Discrepancy Report Form provides a method of logging equipment and system discrepancies/faults that have occurred on a commissioned system. The form is to be completed and should accompany any returned equipment In the event that it is not practical to return the faulty equipment due to its size or installation, the form should be returned to GE as a means of advice of a problem.
Any failures found should be reported to the supervisor/manager.

1 SERVICE A

1.1 Check that the power supply is functional and that its ventilation is not obstructed.

1.2 Check that the link between the TDM systems (field to office) is reported as OK, rectifying any defect.

1.3 Check the power supply indications are indicating correctly for all units.

1.4 Check that the DCD LEDs on any fitted modems are lit.

1.5 Check that there are no fault indications lit.

2 SERVICE B

2.1 Check that all power and serial cables are plugged in and retained to the unit. Do not over tighten the jackscrews / retainers.

2.2 Clean the unit housing using a proprietary anti – static cloth, used in accordance with the manufacturer's instructions.

End

ESD Precautions.

Before working on system use appropriate ESD precautions.

General

The GE Leicester Keyboard/Trackerball unit is a replacement solution that effectively emulates the original interface connections to the Vaughan Keyboard/Trackerball and is transparent to the signallers.

Records.

All activities carried out on the unit shall be recorded in line with current maintenance standards.

A Discrepancy Report Form provides a method of logging equipment and system discrepancies/faults that have occurred on a system. The form shall be completed and shall accompany any returned equipment In the event that it is not practical to return the faulty equipment due to its size or installation, the form shall be returned to GE as a means of advice of a problem.

Any failures found should be reported to the supervisor/manager.

SERVICE A

1.1 Check the link between the unit and the Train describer is OK by checking the cursor moves on the map display with the trackerball movement and that the keyboard characters echo back on the map display. Rectify any defect.

1.2 Check the power supply indications are indicating correctly on the Fanless PC and its power supply.

1.3 Check that the there is a working keyboard/trackerball spare on site

SERVICE B

1.4 Clean the keyboard, trackerball and PC housing using a dry lint-free cloth.

1.5 Check all signal and power connections to the PC are made and where applicable secure. Do not over tighten screw-locks.

PERIODIC TASK

1.6 Send the PC to the supplier for service of battery and hard drive.

End

Includes:	Synelec LMR 1000-50 cube units & LMR 1200- 84 projector & lens
Excludes:	All other Route Display Systems

General

Before working on the system ESD precautions shall be taken.

The Rugby Whole Route Display System utilises the Synelec LMR1000-50 cube units, which comprise of the mechanical structure, the LMR1200-84 projector, and lens. A maintenance PC, installed with the Combase software, is provided that connects to all the cubes via an Ethernet LAN.

This can be used to control the projector functions. Projection lamps will be run until they fail therefore routine lamp changing will not be carried out.

More information on the system can be obtained from the manufacture's manual.

Records

All activities carried out on the system shall be recorded in the system log book.

SERVICE A

1. Screen Cleaning

1.1 As required, clean the front screen with a clean lens cloth.

SERVICE B

2. System Inspection

2.1 Check the condition and the display quality of the system. Ask the Signaller(s) if they have any problems.

This should include the physical condition of the hardware and the projector adjustment.

Any problems should be addressed if possible, prior to continuing with the servicing.

3. System Maintenance

3.1 Check the alignment between projectors. Adjust if necessary.

For very poor alignment use the grid pattern. More information on this can be found in the Mechanical Adjustment Lite Master 50" Series manufacturer's manual.

Check for correct colour balance and adjust if necessary, using the Combase software. More information on this can be found in the Mechanical Adjustment Lite Master 50'' Series manufacturer's manual.

3.2 Check that all cables are secure and undamaged and that they are all screwed into position.

Extreme care should be taken when performing this task as 380V is present on one of the cables.

3.3 Check the image processing electronics. Check that all the cooling fans are working, rectify as necessary. Check that filters are clean and change if necessary.

Check that all the connectors are in position.

4. Cube Cleaning

4.1 Dust the projector casings. Clean the projector lens with a clean lens cloth. Mirrors should not need cleaning, but when necessary clean only with a clean lens cloth.

The inside of screens should not require cleaning on each visit but should be monitored and cleaned when necessary. The same cleaning procedure for lenses and mirrors apply.

5. Final

5.1 Check that all projectors are closed and securely fastened. Check that the Signaller(s) are satisfied with the quality of the displayed images.

END

1. Cambrian Lines (ERTMS)

1.1 System Overview

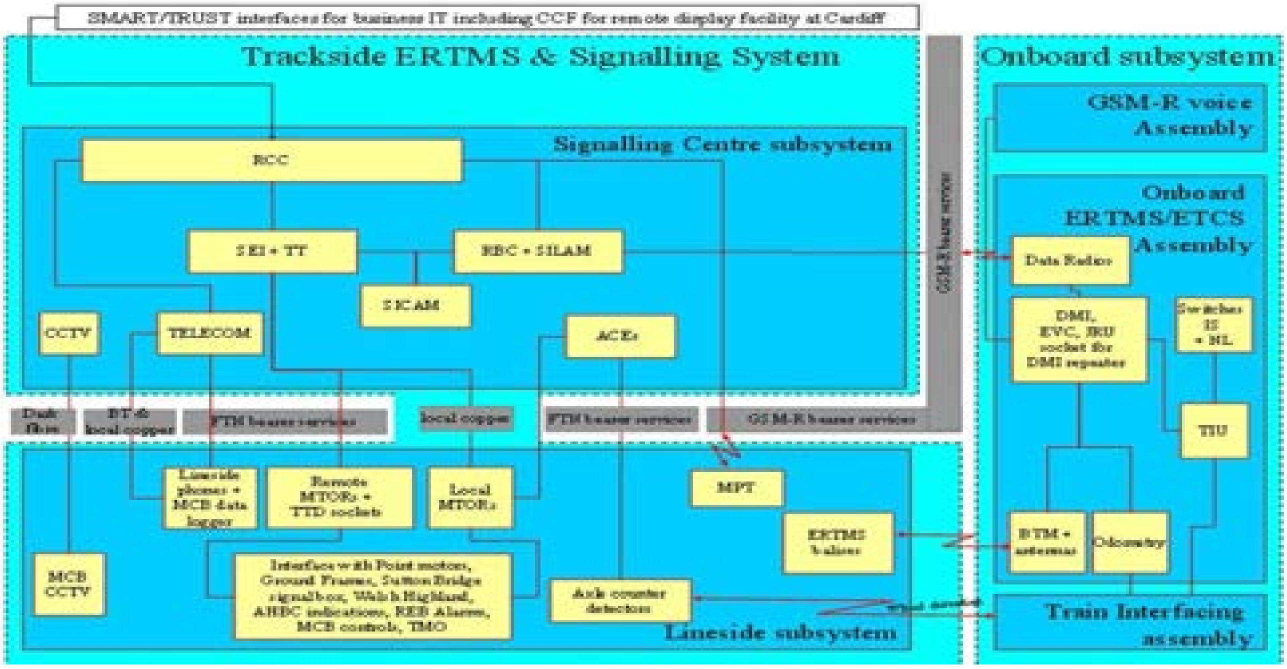

Figure 1 - Schematic Layout of the Cambrian System

1.2 ERTMS Abbreviations

Abbreviation	Meaning
ACE	Axle Counter Evaluator
AHBC	Auto Half Barrier Level Xing
BTM	Balise Transmission Module
CCTV	Closed Circuit Television
DMI	Driver Machine Interface
EVC	European Vital Computer
IS	Isolation
JRU	Juridical Recording Unit
MCB	Manual Crossing Barriers
MTOR	Object Controller
MPT	Mobile Protection Terminal
NL	Non-Leading
RCC	Route Control Centre
RBC	Radio Block Centre
REB	Relocatable Equipment Building
SEI	Interlocking
SICAM	Central Maintenance Aid Equip
SILAM	Local Maintenance Aid Equip
TMO	Trainman Operated Level Xing

Abbreviation	Meaning
TT	Technicians Terminal
TTD	Technicians Terminal Remote
TIU	Train Interface Unit

Table 1 - Abbreviations

1.3 General

The European Rail Traffic Management System (ERTMS) is a cab-based speed signalling system providing automatic train protection (ATP) and is designed to standardise the train control systems of Europe.

ERTMS is the collective term for the following:

a) European Train Control System (ETCS) – Automatic Train Protection (ATP).

b) GSM-R – Standardised mobile communications system for railways that can handle voice communication between the Signaller and train driver as well as data communication between the signalling system and the on-board train ETCS equipment.

The Cambrian lines operate in ETCS Level 2, the principle elements of Level 2 are:

a) Continuous voice communication between the train and Signalling Control Centre (SCC) via GSM-R.

b) Continuous data communication between the train and Signalling Control Centre (SCC) via GSM-R except for defined radio holes.

c) Intermittent communications via Eurobalise to trains.

d) Movement Authority is requested by trains and issued by the Radio Block Centre (RBC) when all necessary conditions are met.

e) Continuous train detection on running lines is by axle counter.

f) Local track circuits are provided to operate level crossings.

g) Fixed block principles are used to separate trains.

h) Line side signals have generally been removed.

i) Degraded mode signalling is provided, train separation achieved by fixed block markers and speed controlled by degraded mode speed signs.

The interlocking system is provided by a 2-out-of-3 Computer Based Interlocking (CBI), the Ansaldo CBI is known as the SEI.

The Radio Block Centre (RBC) enables communications to be made between the SEI and the on-board train ETCS equipment via the GSM-R data radio.

The RBC is a 2-out-of-3 safety processor using similar architecture to the SEI and is configured to confirm only valid messages are transmitted. It also receives position and other information from trains operating within the area of supervision.

All messages between the RBC and trains are encrypted and communications are established by comparing ERTMS Radio Keys loaded onto the RBC and those loaded onto on board units.

Security of these keys is critical therefore copies of the ERTMS Radio Keys shall be stored in a secure specified location.

The contents of any medium on which they are stored shall not be copied or provided to third party.

Separate procedures are in place for the security of ERTMS Radio Keys and only authorised persons shall amend, distribute, receive, store or upload ERTMS Radio Keys.

Lineside signals are only provided in the transition area between the ERTMS and conventional signalling at Sutton Bridge Jcn and in the train maintenance depot at Machynlleth. Lineside markers and speed signage is provided for use when operating in degraded mode.

Moveable items of the infrastructure are sent commands and return indications to the SEI via Object Controllers using the Fixed Telecommunication Network (FTN) or British Telecom (BT) fibre optic networks.

Train detection for train separation is by axle counter, these also use the FTN or BT fibre optic networks to communicate with their respective Axle Counter Evaluator (ACE). All detection points report into one of the four ACE located in the SCC at Machynlleth.

Balise are installed centrally between the rails at intervals along the line, they can be single units or form part of a group using up to four individual balise.

These are passive programmed devices that only transmit data to trains when activated by the train on board equipment.

The data received by the train can include its position in meters, awakening function, text messages, stop messages, etc. This information is used to enable various on-board functions.

e.g. Preventing trains from exceeding the permitted limits of shunt or degraded mode moves, display of text messages on the Driver Machine Interface (DMI) i.e. "AOCL AHEAD", wheel diameter calibration etc.

1.4 GEST

Temporary and Emergency Speed Restrictions (TSR & ESR) are imposed by the Signaller who sets the requirement for a restriction on a screen called the GEST located in the SCC.

When a restriction is activated the GEST updates the RBC which in turn modifies the data sent in the Movement Authority for the area of the TSR or ESR.

No on-track equipment is required to notify drivers of the position of a TSR or ESR as details are displayed to the driver on the in-cab Driver Machine Interface (DMI) screen.

The on-board equipment calculates the braking for the restriction and displays this to the driver on the DMI.
